In point of fact, Archbutt concludes from experiments which he has recently communicated to the Physical Society that the addition of 1 per cent of free fatty acids to a mineral oil lowers the frictional coefficient to the same extent as does 60 per cent of pure rape oil, and thus lends support to the contention that it is not the glyceride, but the free fatty acid in a compounded oil which improves its lubricating value. The theory that the action of the fatty acid is due to the fact that the interfacial tension between oil and water and between oil and mercury is greatly lowered by the addition of fatty acid to a mineral oil has met with criticism, and it has been pointed out that, although neutral rape oil added to mineral oil greatly reduced the friction coefficient, the interfacial tension between neutral rape oil and water was nearly as high as that between mineral oil and water. In the lubrication of a shaft or journal running at a fairly high speed and under moderate pressure, the bearing is separated from the journal by a film of oil, and the friction is solely due to the viscosity of the lubricant. That property of a lubricant which is not viscosity and is termed "oiliness" becomes important only when the conditions are such that solid or "contact" friction occurs, and all recent work points to the fact that it is the chemically reactive unsaturated constituents of lubricants which promote "oiliness" and that they do so by entering into physicochemical union with the solid faces lubricated, forming new composite surfaces with lower surface energy and opposing less resistance to shear than the unlubricated surfaces. The greater activity of free fatty acids is quite in accordance with this theory.

Our Knowledge of Vegetable and Animal Oils

(10) It will be manifest from the foregoing brief summary of our present knowledge on this subject that a very wide and extremely important and absorbing field of research is open not only with reference to mineral oils but including also the vegetable and animal lubricating oils and perhaps synthetic compounds of know composition and ascertainable lubricating efficiency.

The number of lubricating oils derived from vegetable and animal sources is limited, and the chemical constitution of these oils, with some exceptions, is fairly well known. They are composed of the esters of trivalent and monovalent alcohol radicles, containing saturated and unsaturated fatty acids. The particular esters contained in the different oils and fats have to a large extent been identified, and their quantitative proportions can in some cases be stated approximately. Further research is most needed in the case of the sperm oils, the particular alcohols and acids of which are still quite unknown. Castor oil also needs further investigation. The number of different esters in each vegetable and animal oil is comparatively small. The oil or fat yielded by each kind of seed or animal tissue is sufficiently uniform in composition for its lubricating value to be known from past experience. The knowledge that we lack in the case of these oils is the relative lubricating values of the individual esters composing them, and as all the natural oils are mixtures, it is desirable that the pure esters should be prepared and their lubricating properties determined.

With mineral lubricating oils the circumstances are entirely different. The number of these oils is very large, and our knowledge of their composition very incomplete. We know that they consist in the main of hydrocarbons of different series, some saturated and others unsaturated. We know broadly, but very incompletely, the principal series of hydrocarbons existing in the lubricating oils that are manufactured from the crude petroleum obtained from the different oil fields, but we have no knowledge of the quantitative composition of these oils nor of the chemical constitution of any of the particular hydrocarbons composing any particular oil. We are also possessed of very little information as to the relative lubricating values of the different series of hydrocarbons. If the number of mineral lubricating oils were as limited as that of the vegetable and animal oils, if they were definite products like the oils naturally occurring in vegetable and animal tissues, it would not be a difficult matter to learn by experience the lubricating values of the different oils, and a knowledge of their

constitution would then be of secondary importance to the user of lubricants. But the variety of mineral lubricating oils is so great and their composition so variable and so dependent upon the process of manufacture that it is a matter of the utmost importance for us to be able to analyze these oils. For this purpose it is desirable to determine the nature and relative proportions of their constituents, and also to separate the main constituents from each other and determine their relative values as lubricants.

A Suggested Research Program

The main lines on which research is needed may be summarized as follows:

(1) To isolate and determine the nature of the hydrocarbons in mineral lubricating oils which especially promote the properties of viscosity and "oiliness."

(2) To determine the classes of hydrocarbons desirable in lubricants required to work under high pressures and high temperatures, particularly as regards their relative stability under the conditions obtaining in internal combustion engines, steam engines and air compressors.

(3) To study the causes and means of preventing the formation of carbonaceous deposits from lubricating oils under the conditions named in (2), with special reference to the nature of the hydrocarbon and non-hydrocarbon constituents of such oils.

(4) To study the causes of emulsification in circulating oiling and in splash systems, with special reference to (a) the influence of the oxy- and thio-compounds in mineral oils, and (b) the characteristics of oils with non-emulsifying properties.

(5) To study the causes and conditions of oxidation of hydrocarbons at elevated temperatures.

(6) To determine the direction in which the processes of manufacture can be modified so as to lead to the production of lubricating oils of improved types.

(7) To discover new methods of analysis that will enable the chemist when examining a lubricating oil in the laboratory, besides determining its viscosity, specific gravity, flashpoint, etc., to determine the constituents of the oil and with the help of the knowledge gained under (1) to (5) to measure its ability to reduce friction and to meet the conditions of speed, load, temperature and atmosphere in which it is required to work. Much of this information can be ascertained today only by the costly method of trial.

(8) To elaborate further methods of producing lubricants synthetically in order to meet special requirements. Dicresyl-carbonate, for example, has been used as a lubricant. Reduced naphthenes, glycerides of naphthenic acids and cinnamenes have been prepared and shown to have lubricating value. It might be found possible to produce lubricants whose rate of change of viscosity is less and whose freezing point is lower than is the case with existing lubricants.

(9) To prepare in a pure state the esters met with in animal and vegetable lubricating oils and determine their relative lubricating values.

(10) To investigate the claim that the free fatty acids present in commercial fixed oils are the active constituents which enable these oils to improve the lubricating value of mineral oils, and to investigate further whether the addition of such acids to mineral oils may have any deleterious effect.

(11) To investigate the colloidal nature of lubricating oils and its bearing upon lubricating problems.

(12) To study the effect of ultra-violet light, sunlight and ozone upon lubricating oils.

(13) To investigate the phenomena of dissimilar surfaces (oil and metal) in contact, especially in relation to the property of "oiliness."

Testing Oiliness by Friction-Testing Machines

By Winslow H. Herschel
Associate Physicist, Bureau of Standards

Viscosity is the only property of a lubricant which lends itself readily to mathematical treatment and which is usually taken into consideration in investigations of the laws of fluid friction. Oiliness is a more elusive property, which has been defined as the property which causes a difference in friction when two lubricating oils of the same viscosity at the temperature of the oil film are used under identical conditions.[1]

Oiliness has little or no effect under conditions of complete film lubrication, but a change of bearing metal will produce a marked change in friction and of carrying power under conditions of speed and pressure when a change from one lubricant to another of the same viscosity will produce no effect. High pressures, wide clearance, low speeds or low viscosity have a tendency to produce a condition of incomplete film lubrication in which differences in the lubricant in regard to oiliness may be detected. It is generally recognized that fatty oils are superior to mineral oils in regard to oiliness, and hence fatty or compounded oils are in general use on gearing and for cutting oils.

There is coming to be a fair agreement that oiliness is due to some form of interaction between the lubricant and the bearing metal, although different investigators may speak of it as adhesion, adsorption or interfacial tension. There is therefore nothing illogical in the view of Von Dallwitz-Wegner[2] that oiliness is a joint property of liquid and metal, although varying only with the one if the other remains constant. In this paper it will be considered that the bearing metals are constant and that oiliness is a property of the lubricant.

Methods of Measuring Oiliness

Considerable work has been done in England in measuring oiliness by the use of special apparatus such as the Lanchester oil gear-testing machine[3], the Deeley oil friction-testing machine[4], and the interfacial tension apparatus of Donnan[5]. This last-named apparatus is open to the objection of making it necessary to assume that the relative interfacial tension between the lubricants and some liquid is the same as the relative tension between the lubricants and the bearing metal.

Bingham[6] suggests eleven different methods of measuring oiliness, the two most immediately available being the use of a lubricant as a cutting oil and the determination of the coefficient of friction of rest by the inclined plane. Wilson and Barnard[7] had the greatest success with the inclined plane and the Deeley friction machine, and also developed two new lines of investigation.

It was found that the flow through metal capillaries, under a constant head, decreased with time, this de-

crease being the more rapid for oils of good oiliness. Similar observations were made by Fulweiler and Jordon[8] with glass capillaries, in investigating sources of error in viscosimetry, but they found that with some oils the flow increased with time. If it should be confirmed that the rapidity of clogging of metal capillaries is a measure of oiliness, this method is very promising as a routine test, because it could be readily standardized and does not necessitate laborious polishing and repolishing of metallic surfaces.

Wilson and Barnard give as a tentative conclusion that in tests with friction-testing machines the location of the point of minimum friction, or critical point, is "lowered by the oiliness of the lubricant." Any conclusion must necessarily be based upon the very meager data available. The literature is full of reports of inconclusive tests on friction machines, where unsuspected variations of roughness and of clearance between rubbing surfaces, as well as uncertainty in regard to the viscosity of the oil film, cause discordant results. It is believed that the following method of reporting tests is of general application and will make results of tests much more intelligible. The method has been used at the Bureau of Standards in an investigation of the possibility of measuring oiliness with an oil friction-testing machine, and it is hoped to report the results of this work in a subsequent paper.

Method of Reporting Results

It is now generally recognized that a journal is eccentric in its bearings, the eccentricity diminishing as the speed is increased. It is also known that the friction varies with the clearance and with the eccentricity, and according to Sommerfeld[9] eccentricity is a function of $\frac{\mu n d^2}{p \Delta^2}$, that is a function of viscosity, speed and ratio of diameter to clearance, divided by the pressure. Hersey[10], who considered all possible factors which might influence the friction, comes to a similar conclusion provided the supply of lubricant is adequate so that friction is independent of the rate of feed and the bearing is free from cavitation or end effects. Replacing Δ, the film thickness of a concentric journal, by 2Δ, the difference in diameter of bearing and journal, the term $\frac{\mu n}{p}\left(\frac{d}{2\Delta}\right)^2$ may be called Sommerfeld's criterion and will be represented by S.

Considering the factors of Sommerfeld's criterion separately, μ is the viscosity, preferably taken in poises, the c.g.s. unit of viscosity, since data on viscosity are usually given in this unit or in times of flow from which values in poises may be determined by suitable equations or diagrams.[11]

Wilson and Barnard[11] plot the coefficient of friction against zN/p, where "z is in centipoises relative to water at 68 deg. F., where it has a viscosity of 1 centipoise = 0.01 poise." As I have taken μ in poises, $z = 100\ \mu$. The viscosity of lubricating oils is high enough so that the poise is at least as convenient as the centipoise, and there is some objection to introducing the idea of relative viscosity since this is so often confused with relative times of flow.

With μ in poises, S will be dimensionless if the pressure, p, is expressed in dynes per square centimeter (1 lb. per sq.in. = 69,000 dynes per sq.cm.), the speed, n, is expressed in revolutions per second, and d and Δ are taken in any convenient unit.

For a given bearing of constant smoothness, the friction is a function of the viscosity if the pressure, speed and clearance are constant. If the viscosity and speed are both variable, the friction will be a function of $\mu\, n$ as plotted by Biel.[12] If μ, n and p are all variables (and they are seldom absolutely constant in actual tests) and the clearance is constant, friction will be a function of $\frac{\mu n}{p}$ as shown by Hersey.[13] It seem preferable, however, to introduce the term $\left(\frac{d}{2\Delta}\right)^2$ and plot the coefficient of friction against S in order to emphasize the effect of the clearance upon the friction, and to prevent a heedless and unwarranted assumption that the clearance was constant when it was not.

According to Sommerfeld the lowest coefficient of friction, or value of f at the transition point, will be

$$f = \frac{2}{3}\sqrt{2}\left(\frac{2\Delta}{d}\right) \tag{1}$$

This will occur when Sommerfeld's criterion has a constant value of

$$S = \frac{\mu n}{p}\left(\frac{d}{2\Delta}\right)^2 = \frac{5}{24\pi^2} = 0.0211 \tag{2}$$

Hersey gives friction curves for ideal bearings, obtained by a graphical method, taking $\frac{2\Delta}{d}$ as 0.001, 0.002, 0.004 and 0.010, for which the values of f at the transition point are 0.00094, 0.00188, 0.00377 and 0.00943 respectively, and agree with equation (1). His values of $\frac{\mu n}{p}$ vary as to the square of the clearance, according to equation (2).

Wilson and Barnard concluded that the value of $\frac{\mu n}{p}$ at the point of minimum friction varied with the oiliness. If this can be confirmed, or preferably if it can be shown that the value of S at the point of minimum friction varies with the oiliness, journal friction machines might be used under certain conditions to measure oiliness.

In the great majority of recorded tests the clearance is unknown. Even in the few cases where the clearance was measured when the bearing was new, it is possible that the clearance changed by wear before the tests were completed. It is none the less desirable, on this account, to introduce the term $\left(\frac{d}{2\Delta}\right)^2$ as a reminder that any interpretation of the results of tests rests upon an assumption in regard to the clearance. When the clearance is unknown, it is convenient to assume that $\frac{2\Delta}{d}$ has the not unusual value of 0.001. Of course the true value should be used whenever known.

A Study of Bearing Metals*

By Christopher H Bierbaum
Vice-President Lumen Bearing Co., Buffalo, N. Y

It is well established that bearing metals must be composed of an intimate mixture of soft and hard crystals, using the term hard to express the capacity for resisting cutting or abrasion. It is now being appreciated more and more that, for the most satisfactory bearing service, the physical properties of the journal bear some relation to the bearing metal, as for best service requirements the bearing and journal must polish each other. Therefore the hardest crystal in the bearing metal must bear some relation to the hardest crystal in the journal. The relative hardness of these individual crystals has not been studied heretofore, and it is with this object in view that the development of the herein described instrument was carried out and study begun.

THE first significant fact observed in the study of bearing metals is that not a single pure homogeneous metal has given satisfactory service; all bearing metals are alloys made up of two or more phases—that is, they consist of hard and relatively soft microscopic particles intimately mixed. The function of the hard particles, or *bearing crystals*, is to support the load and resist the wear when actual metallic contact exists between the bearing surfaces. The functions of the softer particles are to allow the harder particles to adjust themselves to the surface requirements of the journal and to wear down slightly below the surface of the harder, forming slight depressions on the apparently smooth wearing surface of the bearing, in which some of the lubricant is held when the bearing surfaces are brought into contact with each other. It is this characteristic of certain alloys to form these slight depressions, and thus provide the means for retaining a lubricant, that characterizes them as true bearing metals; in fact, a bearing metal has been defined as "an alloy that is capable of retaining a lubricant upon a bearing surface."[1] The extent to which the lubricant can be so held determines the most valuable characteristic of an alloy as a bearing metal.

An alloy that, perhaps, most characteristically represents a bearing metal is the composition of copper and tin that contains sufficient tin to produce the tin-copper eutectoid, or delta crystal. The depressions worn upon the surfaces of the softer crystals of the teeth of a motor-truck worm wheel, made of an 11 per cent tin bronze, in many cases were from 5 to 6 microns in depth; all other conditions remaining constant, this depth of wear increases with an increase of working pressure. This copper-tin bronze contains intercrystalline shrinkage cavities, which also tend to retain the lubricant, and the relatively low fusing temperature of the delta crystal permits the same, under severe treatment, to fuse upon the bearing surface, while it is being "run in." It is the dissimilarity of the component crystals, both in physical properties and in chemical composition, that makes bronze a bearing metal, and it is the similarity in physical properties and chemical composition of the component crystal that makes brass unsuited for this purpose.

Metals, as cast in the foundry for bearing purposes, are not in a state of equilibrium; they, therefore, must be studied in the condition in which they exist under service conditions. In fact, the value of controlling the chill effect on alloys, thereby rendering them especially serviceable for bearing purposes, is being appreciated more and more. In the copper-tin bronzes, where the delta crystal is desired, the chilling must be done with care; excessive chilling reduces the amount of this eutectoid formed, while cooling too slowly produces an undesirable coarse structure. Some other alloys cannot be chilled too suddenly, especially those in which it is important to reduce the grain size to a minimum. A bearing surface of bronze cast on a carbon chill, having grains of microscopic size, showed that, because the grains presented different angles of orientation, they wore at different rates, producing slight unevenness on the bearing surfaces, for which reason the grains, in a limited manner, caused a functioning of this bronze as a bearing metal.

So far all efforts to make accelerated wearing tests on bearing metals have failed because these tests are not made under service conditions, while tests made under service conditions are so prolonged that they lose their value. In almost all laboratory tests the softer, or more readily conforming, alloys are favored, as they are "run in" in a shorter time. The test of a readily conforming bearing metal upon the hardened-steel arbor of a testing machine is meaningless, when considering practical requirements; a bearing alloy should be tested against the same metal with which it is to be used in service.

The only physical tests on a bearing alloy, in the aggregate state, that can have any possible practical value are those for determining its physical properties and its safety factor for withstanding the treatment to which it is to be subjected under service conditions and temperature; all other conditions relating to bearing metals are of a microscopic nature and depend on the physical properties of the individual crystals constituting this metal.

If a journal could be fitted so as to be absolutely smooth, true and cylindrical, and additional polishing in service would be neither possible nor necessary, the journal could be made of a material having infinite hardness; but a journal of infinite hardness, not having a theoretically accurate surface, could not possibly give satisfactory wear with any bearing metal. In service, the bearing surfaces must polish each other; therefore, the hardest particles in one member must bear a definite relation to the particles in the other; to insure best results, they must be of the same order of hardness. For a long bearing life, there should be a polishing effect between the two metals rather than an abrading tendency.

When studying the abrasion or polishing effected in

*A paper to be read before the February, 1923, meeting of the Institute of Metals Division.

[1]Report of sub-committee on bearing metals, A.S.M.E. (1919).

a new bearing, we find that the worn-off particles of metal, carried away by the oil, gradually decrease in size. In a new bearing, made of proper material and correct design, though poorly fitted up, the first particles worn off may be large enough to be seen with the naked eye; but as the operation continues the particles become microscopic and then ultra-microscopic in size. The largest abraded particles resemble ordinary filings, but as they decrease in size they become spherical in form. This statement is made with due consideration of the fact that for a proportionate decrease in size of particles, the resolving power of the microscope also decreases. In the coarser abrasions, we may find entire crystals, which may be considered as only incidental in reducing the bearing to proper working conditions. In the operation of a long-life bearing, giving satisfactory service, the wearing is of a microscopic or ultra-microscopic order and represents the abrasion of correspondingly small particles of one member upon those of the other.

From the foregoing, it seems obvious that a study of bearings, without taking into consideration both members, could not be conducive of practical results. It is also obvious that a knowledge of the physical properties, especially of the abrasion hardness of the different microscopic constituent elements of a bearing alloy, as well as those of the journal, is imperative.

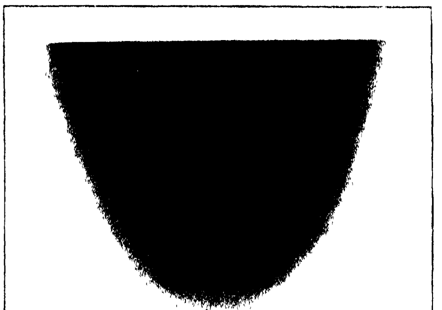

FIG. 1 SHADOWGRAPH SHOWING POINT OF FINEST CAMBRIC NEEDLE, SHARP'S NO. 12. × 2,000

A natural suggestion for testing on so small a scale was to reduce present methods to a corresponding degree of refinement; this at the outset proved impractical. In fact, all methods for testing any one crystal at a time failed, if for no other reason than its difficulty of application. A fact sometimes observed upon a metallographic specimen, polished on soft broadcloth, is that a continuous sharp cut, crossing several crystals, is wider on some than on others; this fact suggested the development of the instrument herein described.

The following fundamental requirements were established, after somewhat prolonged experimentation: (1) The cutting point must be ground with an extreme precision and to definite specifications; its shape must be such that the vertical pressure exerted upon the surface tested will be greater at all times than the horizontal pull applied to the point. (2) The cutting point must be so mounted that it can respond to required successive elevations with the least amount of inertia to overcome, and it must exert a constant pressure while passing over the test surface. (3) The cutting point must be moved over the test surface at a uniform rate, slowly enough so that no additional indentation may occur by stopping on the softest crystal.

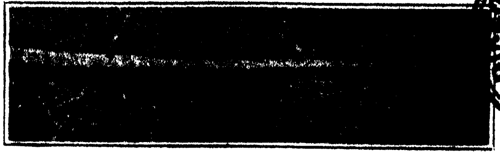

FIG. 2—PHOTOMICROGRAPH OF SOFT-STEEL SURFACE SHOWING END OF MICROCUT. × 2,000

Various materials were experimented with when seeking a suitable cutting point: one that would be hard enough for all ordinary metals and their alloys, if possible including hardened tool steel; one having the necessary hardness and the microscopic homogeneity to permit it to be ground to an extremely accurate point. On account of its hardness, the diamond was the first material suggested, but its grinding has proved unsuccessful. Various other jewels have been tried, the sapphire, tourmaline, ruby, garnet, also various grades of special steels and tungsten. The artificial leuco sapphire (fused Al_2O_3) has proved extremely satisfactory, in that it has the necessary homogeneity, and is much harder than the crystals in the ordinary metals, including martensite in hardened steel and tin oxide (fused SnO_2). The latter is the hardest crystal so far encountered in any of the alloys or their impurities; its hardness is more than twice that of martensite.

The importance of a knowledge of the hardness of the individual crystals of the alloys was appreciated by the early investigators, when applying the microscope to the study of metals. Their investigations, however, were crude, in that they applied the points of steel needles in their work. The crudeness of any work done with a needle is evident from the shadowgraph, of 2,000 magnifications, of the point of the finest cambric needle, Sharp's No. 12, given in Fig. 1; in Fig. 2 is shown the end of a microcut made upon soft steel with a sapphire point ground to definite specifications. The point itself appears sharp under 2,000 magnifications.

After the selection of a suitable jewel, considerable difficulty was experienced in grinding a point that would be sharp and accurate to the extreme limits of the microscope. The grinding of a conical point was early abandoned as being impossible; the point that was finally ground successfully was the corner of a cube or a solid right angle. Fig. 3 gives the details of this point, (1) showing an end view and (2) a side view. The jewel was cylindrical in form 0.022 in. in diameter and 0.08 in. in length. It was cemented securely into a close-fitting hole in the end of the grinding stylus that made an angle of 54.73 deg. with the grinding disk. Three successive facets were ground upon the end of the jewel after successively rotating it through 120 deg., thus making the point the corner of a cube. The jewel point is mounted so that the diagonal of the cube shall be normal to the surface to be tested and with one edge advancing directly in line of motion. After grinding, the jewel was placed in a jig and, after all adjustments for accuracy had been made, cemented into the end of a flexible spring, while both

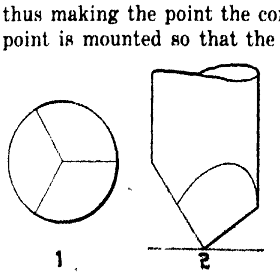

FIG. 3—DETAILS OF JEWEL POINT

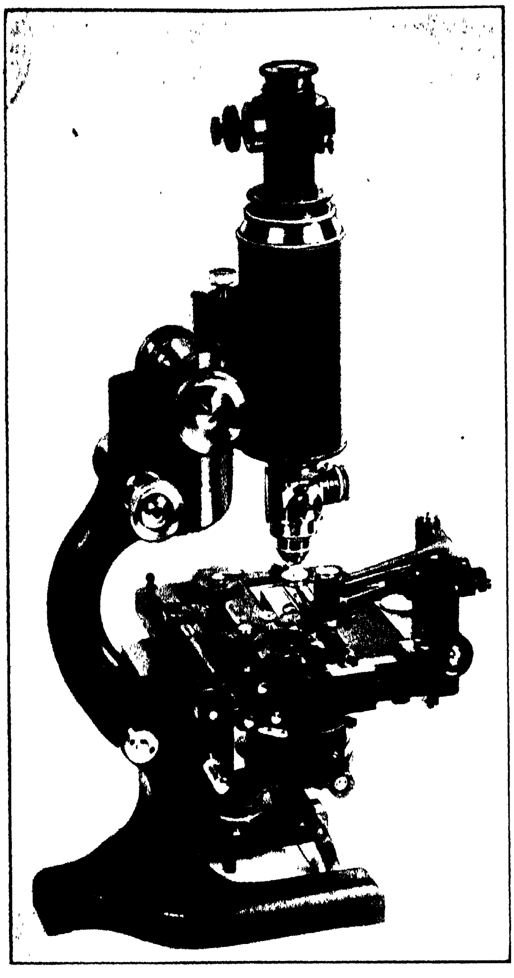

FIG. 4—MICROSCOPE COMPLETELY EQUIPPED WITH MICROCHARACTER AND MICROMETER EYEPIECE

the jewel and spring were held in the jig in the field of the microscope; the cement was a heavy solution of specially refined shellac. After the cement was thoroughly hardened, the excessive length of the jewel was ground off to reduce it to a minimum weight.

Fig. 4 shows a microscope complete and ready for work, equipped with the instrument developed for research on bearing metals; the name chosen for the instrument is Microcharacter. The instrument may be described as a mechanical stage with two additions, the jewel bracket at the right and the micrometer feed at the left. The jewel bracket, as shown in Fig. 5, is provided with a vertical rack for raising and lowering the bracket that carries the jewel suspension. This jewel suspension consists of a balanced arm, pivoted on sapphire bearings, one end of which is provided with a spirit level and the other with a weight, which constitutes the load for the jewel point. The jewel is mounted in the small end of a tapered steel spring, the other end of which is fastened to the lower side of the suspension arm. The suspension bracket is also provided with two adjusting devices, by which the microcut can be located so as to appear in the field of vision. These devices are not absolutely necessary, but are desirable, in that they make possible the testing of a crystal that may be selected in the field of the microscope. A worm and wormwheel attached to the longitudinal movement of the mechanical stage constitutes the micrometer feed.

The specimen to be studied should not be more than ¼ in. thick, and from 1 to 2 sq.in. in area; it should be placed upon an ordinary microscopic slide, leveled, and held in plasticine. After the specimen is in place, the jewel point is brought down upon it and the jewel suspension, by aid of the spirit level, is brought into a level position; this insures that the full load of the weight is being exerted upon the jewel point. The specimen is then moved along under the jewel point by

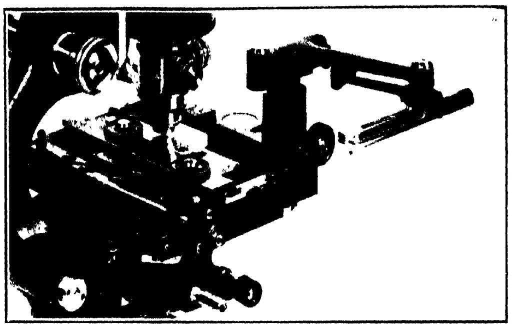

FIG. 5—MICROCHARACTER WITH JEWEL SUSPENSION BRACKET SWUNG OUT

the micrometer worm and wheel actuated by turning the small handle. A drop of oil should be placed upon the test surface and in contact with the jewel before starting, for a somewhat smoother microcut is then made. After the microcut has been made, the jewel bracket is elevated, by turning the knurled head, and swung out of position, as shown in Fig 5. The objective is brought into focus upon the microcut and, after it has been studied through a plain ocular, the micrometer eyepiece is substituted and the widths of the microcut are measured.

$$\kappa = \lambda^{-2}\,10^4$$

FIG. 6—FORMULA, TABLE AND DIAGRAM OF SCALE OF MICROHARDNESS

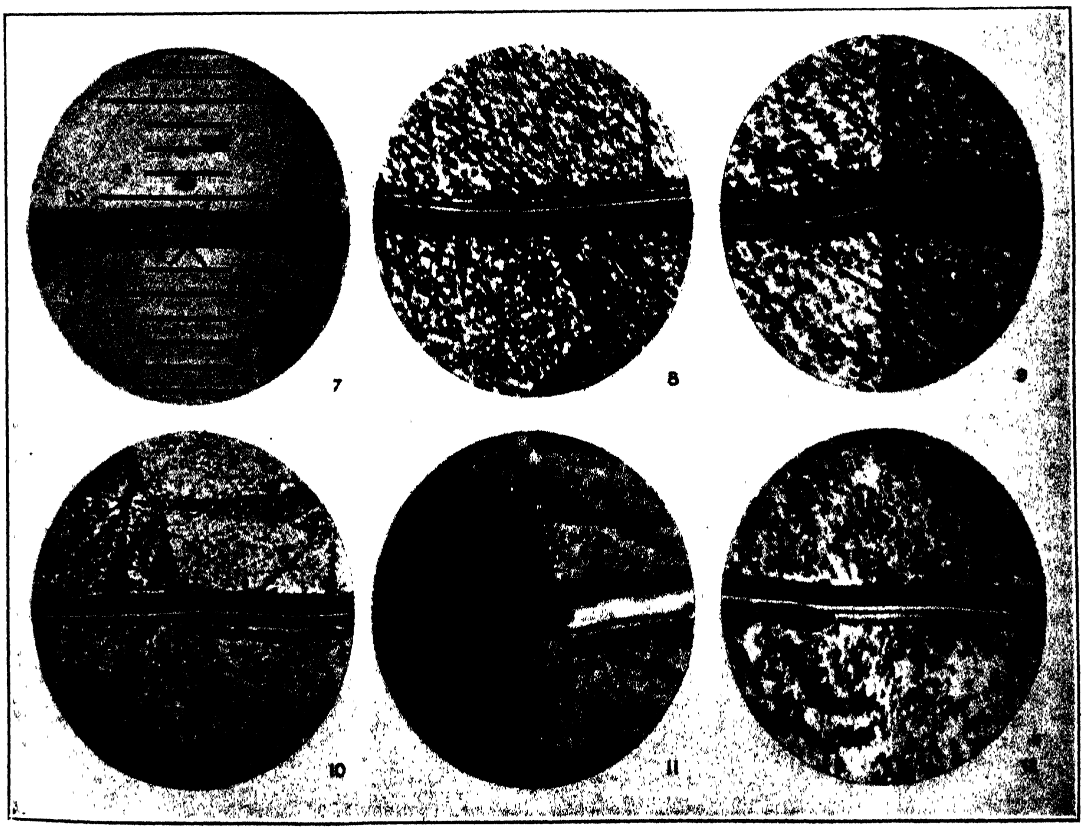
Fig. 7 shows a view of a microcut through the micrometer eyepiece; the focusing, of course, should always be done upon the original surface of the specimen. The X of the scale is moved to one edge, in which position a reading of the vernier is taken; after moving the X of the scale to the other edge the second reading is taken; both edges should be approached in the same direction. The difference between the vernier readings gives the fractional parts, whereas the full units can be read directly. It is necessary to calibrate the scale of the micrometer eyepiece by comparing it with the scale of a stage micrometer, for which the working set-up of the microscope should be used. The micrometer eyepiece scale is then calculated, in terms of microns, and the reading of the width of the microcut multiplied by this factor reduces the reading to terms of microns. A 2-mm. apochromatic objective with 160-mm. tube length and a 20× micrometer eyepiece with a ½-mm. scale gives substantially 2.5 microns per unit of scale division. A convenient weight upon the jewel point seems to be 3 grams, as with this load readings can be made upon the softest lead as well as upon the hardest steel without any change in the microscope set-up.

The micron, 0.001 mm., seems to be a convenient unit for our purpose. As the various cross-sections of microcuts in the different metals and alloys are symmetrical and their areas are proportional to the squares of their respective widths, these squares should be used for comparison. The same should appear as a factor in the mathematical expression for the value which may be designated as microhardness. For the reason that the greater widths represent the softer material the reciprocal of these squares should be used. Let κ represent the microhardness and λ the width of microcuts, then after multiplying by a convenient constant, to avoid unwieldy numbers, $\kappa = \lambda^{-2}10^4$. In Fig. 6 this formula has been plotted to two rectangular co-ordinates covering an ample range of microhardness.

The microhardness of grains in most metals varies in different directions; that is, if a grain on a polished metallographic specimen is cut in different directions the results vary within certain limits, and these limits vary for different metals. This property is illustrated by Figs. 8, 9 and 10. Fig. 8 shows a uniform width of microcut upon a surface of chemically pure copper. The two grains, of necessity, have a different angle of crystalline orientation but they presented approximately the same angle to the surface and the direction of the microcut, so the two crystals present an equal degree of microhardness. Fig. 9 shows the same two grains as in Fig. 8, but the direction of microcut is different, with the result that maximum and minimum microhardnesses are shown.

Fig. 10 shows the greatest difference of microhardness, so far encountered, for chemically pure metal; it shows a microcut of maximum and minimum widths for electrolytic zinc.

Fig. 11 shows a crystal of fused tin oxide imbedded in



FIGS. 7 TO 12

Fig. 8—Microcut in two adjacent grains on pure copper having same apparent hardness. × 875.

Fig. 11—Microcut upon fused tin oxide and bronze. × 875.

Fig. 9—Microcut on same crystals as in Fig. 8 showing maximum and minimum microhardnesses of chemically pure copper. × 875.

Fig. 12—Microcut upon slightly etched hardened tool steel. × 1,250.

bronze. The narrow width of microcut indicates the extreme hardness of the crystal which is found only in bronze that has been heated above the fusing temperature of tin oxide. It has long been known that "burned" bronze was destructive to bearings. The actual hardness of the crystal, however, does not seem to have been determined before this as being more than twice that of hardened tool steel; it is by far the hardest crystal found in any of the common alloys or their impurities.

Fig. 12 shows a microcut in hardened tool steel; the martensite formation is distinctly seen.

Heat tinting or very light etching may be used for the identification of crystals; the etching, however, should always be very light in order not to affect the results. This method of testing offers strictly comparable results, for a single microcut upon a substance of, say, unit microhardness would disturb as large a volume of material as 100 microcuts on a substance having a microhardness of 100. Should conditions require the hardness of the diamond, there is no doubt that it can be ground to this same degree of refinement and results obtained uniform with the present. While it is desirable that the instrument fit the microscope stage it is not absolutely necessary that it should; a plain stand may be improvised, and after the microcut is made the specimen can be transferred to the microscope, where all measurements can be made in the usual way.

By the use of this instrument, it has been clearly shown that the addition of zinc in excess of 2 per cent to a copper-tin bearing bronze increases the hardness of those crystals which, without the zinc, would have been the softest. This addition of zinc, therefore, tends to reduce the range of hardness between the hardest and softest crystals and theoretically reduces the bearing value of such an alloy. This offers a most striking corroboration between theory and practice, for it has long been known that the hardening of bearing bronzes by the addition of zinc increases the rate at which they wear off in service, and that this destructive wearing effect increases with an increase of zinc content.

Name of Substance	Width of Microcut, Average	Microhardness, Average
Lead, c p., Picher	37.7	7.03
Tin, c p., electrolytic	29.3	11.7
Copper, c p., Raritan	11.8	78.4
Antimony, commercial	9.1	121.0
SnSb crystal as found in babbitt	6.9	208.0
Nickel, c p., International Nickel Co	6.4	244.0
PCu_3 crystal as found in phosphor bronze	6.1	267.0
Iron, Swedish, softest crystal	4.8	420.0
Cobalt, c p., International Nickel Co	4.0	625.0
$SnCu_3$, or delta crystal in copper-tin bronze	3.6	750.0
$SnCu_4$, hardest crystal in high-Cu hardened babbitt	3.2	1006.0
Hardened steel - Johansson test block	2.2	2229.0
SnO_2 (fused) as found in burned bronze	1.4	5390.0

An equally interesting fact was brought out in the study of the distinctive effect that a certain high percentage copper babbitt had on a low-carbon journal; the results showed that the $SnCu_4$ crystal was much harder than any crystal in the steel, which was unexpected and accounted for the result. While this instrument was developed for one patricular purpose, it should prove of greater interest, as it offers means for investigation and research that have not been available heretofore.

Dynamite Blasting Tests

A comparison of the breaking qualities of gelatine and ammonia dynamites under actual working conditions is to be made by the U. S. Bureau of Mines. During these tests a study of the fumes from blasting will also be made. An effort will be made to determine the amount of powder required with a standard round to break a foot of drift in different rocks.

A New Method for Case Hardening

BY FRANK HODSON
President Electric Furnace Construction Co.

A PROCESS which seems to have great possibilities for case hardening was recently shown to the writer by the well-known Swedish scientist, Dr. Assar Gronwall, who will be remembered as the inventor of the "Elektrometall" type of electric shaft ore-smelting furnace and various other electrical processes. Dr. Gronwall also showed a number of examples of this new case-hardening method, and I also had the privilege of examining records of tests made by Prof. Armd Johansson of the Tekniska Hogskolan, Stockholm.

Dr. Gronwall's process is based upon the fact that carbonizing is due to carbon monoxide, which in presence with iron at suitable temperature breaks up into carbonic acid and carbon, which latter, together with the iron, forms carbide of iron. In order to facilitate the process it is usual to mix with the carbonaceous packing a so-called carbonizing powder, such as carbonate of barium, metallic oxides, leather, bone, and even quartz and brick dust, which are supposed to facilitate the formation of CO within the furnace.

It is well known, however, that even using the best cementing mediums, the process is unnecessarily slow and that deep carbonization is very difficult. Dr. Gronwall's experiments proved that the gases inclosed in the case-hardening pots reached the equilibrium between CO, CO_2 and the carbonized steel at the outer surface and therefore the process gradually stops. The new method consists of converting much of the carbonic acid as formed to carbon monoxide. This is done by putting catalyzers of a special metal in the form of thin sheets, ribbons or wires into the box with the carbonaceous matter surrounding material to be case hardened. The catalyzer then acts in such a way that the carbonic acid, when coming in contact with it, changes into carbon monoxide. In other words, the catalyzer displaces the equilibrium in such a manner that the amount of CO in the gas is materially increased.

An iron object may be case hardened deeper on a certain spot by placing catalyzer there; gear wheels were carbonized only on the outer parts of the teeth.

The catalyzer is said not to be consumed during the operation and therefore the cost of the new method consists only of expense of original catalyzers and the license to operate.

With the new method less carbonizing material is needed, the temperature can be kept lower than usual, and time occupied is just about half. The tests at the Technical Academy, Stockholm, consisted in treating pieces of steel from the same bar in an electrically heated furnace, first in the usual case-hardening method and second with the addition of the catalyzer. The amount of case was considerably deeper in the second samples, although time occupied, temperature and other conditions were exactly the same.

Paper Waste Costs $50,000,000 Annually

Efforts to save the nation's forests by the reworking of waste paper was a feature of the past year's work of the American Paper and Pulp Association, which found that 300,000 acres of forest land could be saved by the collection of paper now being burned, which would be worth $50,000,000 a year to the paper mills.

A German Apologia

THE following appeared as an editorial in the *Chemical Age,* London, for Jan. 20, 1923, relative to German comment on a series of articles published by Mr. Negru on "European Conditions as I Saw Them":

"A few days ago an interesting package reached us from Berlin—so insufficiently stamped, it is our painful duty to add, that inspection of its contents could only be obtained by the payment of 8d. excess. On being opened, it was found to contain a pamphlet by Dr. W. A. Dyes, of Berlin, constituting 'an appeal to commonsense,' and a reply to a series of articles which Mr. J. S. Negru, a member of the editorial staff of *Chemical & Metallurgical Engineering,* recently contributed to that journal on German conditions as he saw them during a 6 months' tour of Europe.

"We happened to meet Mr. Negru in New York shortly after his return from Europe. He went there as the representative of one of the most reputable journals and one of the best publishing houses in the United States. His object was to see things as they are, and to tell the American public what he saw. He recounted to us some of the difficulties put in his way. In spite of them he collected a considerable body of facts and published them. It was not to his interest or to that of his journal to write mischievous fiction; the purpose of his visit was to obtain first-hand information, and if as a Belgian he wrote occasionally with some feeling it is only what might have been expected.

"But Dr. Dyes resents his description of German conditions, and seeks to discredit it. One might imagine, if we did not recall such judicial reports as those of Lord Bryce's commission, that Germany had hitherto enjoyed a spotless record, and was entitled to have its word accepted against all other witnesses. If Mr. Negru discovered another side, he is by no means alone, and we know no reason for supposing that he visited Germany for any other purpose than to discover and make known the truth.

SAMPLE OF THE STRANGE PSYCHOLOGY OF THE TEUTONIC MIND

With the immense detail of this 27-page pamphlet we have not space to deal. It is mainly interesting as another sample of the strange psychology of the Teutonic mind. During the war we were privileged to see some confidential German documents containing instructions to their information agents in this and other countries. They were a revelation of German mental ingenuity. And we have something of the same quality here. Out of his well-stocked pigeon-holes Dr. Dyes seems able to produce every favorable reference to Germany uttered since the Flood, and with pathetic belief in their efficacy he employs them to display his country arrayed in white robes. It is the attitude of a highly sensitive man, wounded in his conscience by being thought ill of, and indignant at the slightest aspersion on his honor. To Dr. Dyes it really seems impossible to understand any feelings save those of respect and confidence toward his country.

"As representing those who have no desire to see Germany 'go under,' may we offer him a few words of friendly advice? Throughout the war every device which Germany adopted, whether to inspire terror or to elicit sympathy, almost invariably produced the opposite effect. And Dr. Dyes exhibits just the same lack of imagination now—an immense and most ingenious capacity for seeing things in detail and total blindness to broad moral values and effects.

HOW GERMANY CAN RE-ESTABLISH HERSELF

"If Germany wishes to re-establish herself among the nations, it will not be by meticulous reasoning of this sort. It will be by frankly disowning her recent past, admitting the injustice inflicted on others, and making good the damage. France won the respect of the world by the splendid spirit in which she discharged the crushing penalties Germany imposed on her. The profound respect which Great Britain commands in the United States today is due to the quiet and dignified way which we, the most heavily taxed nation of all, face our obligations. If Germany desires to regain the world's respect, it can be done in the same way, but not by weaving ingenious webs of excuses or reciting long rolls of synthetic virtues or affecting the unsuitable rôle of the innocent and injured party. A little sackcloth and ashes would be far more becoming as well as more convincing."

Some Problems Which Brazilian Manufacturers Must Solve

Lack of Fuel and Inadequate Transportation Facilities Are the Chief Handicaps, but Labor Is Plentiful and Efficient

BY WARREN E. EMLEY

FROM August to December, 1922, I was favored with the opportunity of visiting many industrial plants in Brazil and of making a survey of conditions. Many of the ways of doing things are so radically different from the methods in vogue in this country that a description of them would be at least interesting to North American manufacturers. Before going into detail about any particular industry, it might be well to cite a few facts which have a general bearing on every industry.

Probably the most prominent factor, which has modified all manufacturing processes, is the lack of fuel. There is some coal mined in the most southerly state, Rio Grande do Sul, but this is far away from the industrial center of the country, and besides it is of very poor quality, being extremely high in both sulphur and ash. Serious attempts have been made to use this coal, powdered, in locomotives, but it is not satisfactory unless mixed with a better grade of imported coal. English coal costs 140 milreis (about $17) a ton, delivered at a factory in São Paulo. Oil shale and oil made therefrom are to be found in every museum, but the most careful inquiries failed to bring to light any commercial source of this material. Wood has been, and still is, the main reliance for fuel, but is now getting scarce within economical hauling distance of the factories and railroads. An effort is being made toward reforestation. Groves of eucalyptus extending for miles along the railroads are not an uncommon sight.

The fuel situation is saved by the unlimited supply of hydro-electric power. This has been developed to the point that cheap electricity is available throughout the industrial districts of the country. This dependence upon electric power has brought about a condition which seems peculiar, but is quite logical: a single company

Published by permission of the Director of the Bureau of Standards of the U. S. Department of Commerce.

frequently makes a number of products which bear no relation to one another. Having purchased and developed a waterpower site to supply the primary business of the company and having expanded that business to its present economical limit, there is still some power left over, so that an entirely different industry is started to use this excess power or to use some natural resource which was accidentally acquired with the site. Thus one company makes clay tile, lime and paper; another makes enameled iron utensils, locks and keys and nickel-plated ware. Obviously the name of such a company can give no indication of its activities, a fact which is apt to be confusing to a North American.

The development of water power usually involves the holding of large tracts of land. This is facilitated by the fact that there is no tax on unimproved real estate. However, other taxes are sufficiently plentiful to make up for this lack. There is an annual tax to do business —a sort of license. Each state levies an import or export tax, or both, on all materials crossing its borders. Everything is subject to a retail sales tax. Some of these taxes are levied in gold milreis. There is no such thing as a gold milreis, so the taxes must be paid in paper. Once a week the Bank of Brazil publishes a statement showing how many paper milreis make one of gold, which is, in effect, a weekly change in the tax-rate.

TRANSPORTATION, LABOR AND MACHINERY IN BRAZIL

Transportation is difficult. For local hauling, the two-wheeled cart drawn by oxen or mules is very much in evidence. The system of hard-surfaced highways is growing, but outside of the cities the automobile truck is unknown. Some of the railroads are owned by the federal government, others by private individuals, and apparently the gage is fixed by the whim of the owners. This necessitates transshipment of freight into different cars at nearly every junction point. Distances between cities are great, and small towns are very few in number. In vast areas of the country there are no railroads, transportation being effected only by mules. Even the capital, Rio de Janeiro, must rely almost wholly upon ocean steamers to communicate with such large northern cities as Bahia, Pernambuco and Manaos.

Labor is plentiful, low priced and of excellent quality. It is mostly south European stock mixed with Indian and negro. Their necessities of life are few and easily supplied, so that they can live well on a low wage. Artisans have the pride of workmanship so characteristic of Italians and Spaniards, so that they will not do a poor job, no matter what the boss may tell them.

Machinery is practically all imported, and is very expensive. It is not the first cost of a machine which matters so much. In a land of plentiful labor and power, the efficiency of a machine is hardly worth considering. It is the repair cost that counts. If the smallest part of the machine breaks, it may shut down the entire factory for months until a new part can be imported. This is the important factor deterring manufacturers from a more extended installation of machinery. Many machinery manufacturers maintain agencies and carry a stock of spare parts in Brazil. This is frequently the determining factor in the selection of a particular kind of machine.

Although I visited many different kinds of factories, my interest was centered chiefly on building materials, their manufacture aud use. I hope in succeeding articles to show some of the points of difference between Brazilian and North American methods.

Canadian Experiments With Nitrite Fertilizer

Some interesting experiments were made in Canada during the past year with soda nitrogen. This byproduct of the American Nitrogen Products Co. was first brought to the attention of the Canadian Government Division of Chemistry in February, 1921, when it was being offered on the Pacific coast markets as a nitrogenous fertilizer. The examination of a sample received from the manufacturers revealed the fact that of the total nitrogen present, approximately two-thirds existed in the form of sodium nitrite and one-third in the form of sodium nitrate.

The practical experience with soda nitrogen so far has been limited to the knowledge gained from the results of investigations carried on with oats in the greenhouse at the Central Experimental Farm at Ottawa, with oats and potatoes at the Experimental Farm at Agassiz, B. C., and with potatoes, corn, beans and peas at the Experimental Station at Sidney, B. C.

In the experiment with oats in the greenhouse, soda nitrogen and nitrate of soda, in quantities of each representing applications of 150 and 300 lb. per acre, were compared. In some series of plots the smaller and in another series the larger application was made at seeding time. In two further series the applications were made after the plants had attained 1-in. growth.

Of course, under greenhouse conditions the activities of the nitrifying bacteria would be favored, so that the conversion of the nitrite to nitrate would have taken place almost immediately. Be this as it may, observations made at the beginning and during the progress of the experiment failed to detect evidence of injury either to the germinating seedling or to the maturer plant at any stage.

The heavier applications, whether of soda nitrogen or of nitrate of soda, gave results superior to those from the lighter applications, while the untreated checks were decidedly inferior. The experience at Ottawa was repeated in a field test with oats at Agassiz, B. C.

The results of the experiment with potatoes at Agassiz favor nitrate of soda throughout. Besides the nitrogenous material, each fertilized plot received superphosphate and muriate of potash at the rate of 300 lb. and 150 lb. per acre respectively.

The experiments at Sidney, B. C., were carried out on a small scale with potatoes, corn, beans and peas. Of the corn, beans and peas on the plots receiving soda nitrogen, 90 per cent failed to germinate, whereas germination on the nitrate of soda plants was normal. On potatoes there was much less evidence of injury.

Engineering Tables for Low Pressure Air and Gas

Calculations involving the flow of air at low pressure are simplified through the use of data and charts contained in Bulletin 118, Engineering Tables, published by the P. H. & F. M. Roots Co., Connersville, Ind. The bulletin is designed to give as completely as possible the information which is required in making installations of blowers, pumps and exhausters for various services, such as agitation of liquids, pneumatic conveyors, foundry cupolas, combustion of fuel oil, water-gas sets, etc. General tables complete a booklet which chemical engineers will find very useful.

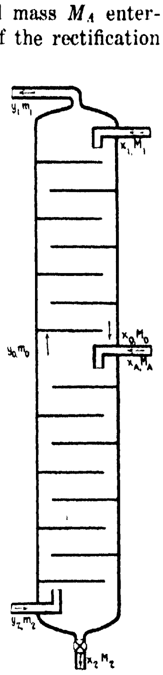
Fundamentals of Rectification

Effect on Rectification of Liquid Feed at an Intermediate Level

Also Conditions for Minimum Reflux and an Example of the Use of the Derived Formula Taken From Liquid Air Fractionation*

BY C. C. VAN NUYS
Chief Physicist, Air Reduction Co., New York City

NOW let us consider the case where we have a liquid of composition x_A and mass M_A entering at an intermediate point of the rectification column.



In what follows, we shall assume that the composition of all fluids entering and leaving the column are given or stipulated. That is to say, x_A, x_1, y_1, x_2 and y_2 are to be considered as constants. Since the equations we shall write take no account of phase relations, we may, if we choose, suppose that x_1 and y_1, and also x_2 and y_2, are compositions of liquid and vapor in phase equilibrium. The only supposition we shall make at present regarding x_A is that its value lies between x_1 and x_2.

We then have six equations containing four M's and three m's, and by means of these equations we may determine the ratio between any two of the seven (M, m)'s.

These six equations are as follows in which m_0 is the mass of ascending vapor passing per unit time the level of admission of the liquid x_A and M_0 is the mass of liquid descending from above at this level.

$$M_1 + m_0 = M_0 + m_1$$
$$I_1M_1 + y_0m_0 = x_0M_0 + y_1m_1$$
$$I_1M_1 + J_0m_0 = I_0M_0 + J_1m_1$$
$$M_A + M_0 + m_2 = M_2 + m_0$$
$$x_AM_A + x_0M_0 + y_2m_2 = x_2M_2 + y_0m_0$$
$$I_AM_A + I_0M_0 + J_2m_2 = I_2M_2 + J_0m_0$$

Let us assume that M_A is fixed arbitrarily, then the values of M_1, M_2, M_0, m_1, m_2 and m_0 may be determined in terms of M_A and of the various x's, y's, I's and J's. This system of equations may be readily solved by properly changing subscripts in the results obtained from the system of three equations solved above. We thus obtain

$$M_0 = \frac{(J_1-I_1)(y_0-y_1)+(J_0-J_1)(x_1-y_1)}{(J_0-I_0)(y_0-y_1)+(J_0-J_1)(x_0-y_0)}M_1$$

$$m_0 = \frac{(J_1-I_1)(x_0-x\ )+(I_0-I_1)(x_1-y_1)}{(J_0-I_0)(y_0-y_1)+(J_0-J_1)(x_0-y_0)}M_1$$

$$m_0 = \frac{[(J_2-I_2)\ (x_2-x_A)+(I_2-I_A)\ (x_2-y_2)]M_A}{(J_2-I_2)\ (y_2-y_0)+(J_2-J_0)\ (x_2-y_2)} + \frac{(J_2-I_2)\ (x_2-x_0)+(I_2-I_0)+(I_2-I_0)\ (x_2-y_2)M_0}{(J_2-I_2)\ (y_2-y_0)+(J_2-J_0)\ (x_2-y_2)}$$

whence

$$[(J_2-I_2)(x_2-x_A)-(I_2-I_A)(x_2-y_2)]\ [(J_0-I_0)(y_0-y_1)-(J_0-J_1)(x_0-y_0)]\,M_A =$$
$$\{[(J_2-I_2)(y_2-y_0)+(J_2-J_0)(x_2-y_2)]\ [(J_1-I_1)(x_0-x_1)+(I_0-I_1)(x_1-y_1)]$$
$$-[(J_2-I_2)(x_2-x_0)+(I_2-I_0)(x_2-y_2)]\ [(J_1-I_1)(y_0-y_1)+(J_0-J_1)(x_1-y_1)]\}\,M_1$$

This value of M_A vanishes if

$$\frac{(J_1-I_1)(x_0-x_1)+(I_0-I_1)(x_1-y_1)}{(J_1-I_1)(y_0-y_1)+(J_0-J_1)(x_1-y_1)} = \frac{(J_2-I_2)(x_2-x_0)+(I_2-I_0)(x_2-y_2)}{(J_2-I_2)(y_2-y_0)+(J_2-J_0)(x_2-y_2)}$$

which is the same equation as that obtained above as the necessary relation between x and y in order for perfect rectification to be possible—that is to say, the amount of liquid of composition x_A that it is possible to add at the intermediate point is zero if the composition y_0 of the vapor having phase equilibrium with a liquid of composition x_0 bears the relation to x_0 as determined by the last equation written.

Now assume that we are dealing with a binary system which has the property described above—viz., the total heat J of the mixture at the dew point and also the total heat I at the boiling point follow the proportionality relation indicated by the equations

$$J = J_Bx + J_A(1-x)$$
$$I = I_Bx + I_A(1-x)$$

so that the latent heat L at constant pressure of any mixture of composition x is given by

$$L = L_Bx + L_A(1-x)$$

For such a mixture the above relation between M_A and M_1 may be easily shown to take the form:

$$\frac{L_Bx_0+L_A(L-x_0)}{L_Bx_1+L_A(1-x_1)}\ \frac{M_A}{M_1} = \frac{(x_0-x_1)(y_2-y_0)}{(x_2-x_A)(y_0-y_1)}$$
$$\frac{L_By_1+L_A(1-y_1)}{L_By_2+L_A(1-y_2)}\ \frac{L_Bx_2+L_A(1-x_2)}{L_Bx_1+L_1(1-x_1)} - \frac{x_2-x_0}{x_2-x_A}$$

Let us denote by l_1 the function $L_By_1 + L_A(1-y_1)$ and by L_1 the same function of x_1 with a corresponding notation for y_0, y_2 and x_0, x_2. Then the last equation may be written:

$$\frac{L_0M_A}{L_1M_1} = \frac{M_A}{M_0} = \frac{l_1L_2}{l_2L_1}\ \frac{(x_0-x_1)(y_2-y_0)}{(x_2-x_A)(y_0-y_1)} - \frac{x_2-x_0}{x_2-x_A}$$

In what follows we shall employ the term "equivalent mass," in speaking of the products L_1M_1, l_1m_1, etc. For example, the equation $L_1M_1 = L_2M_2$ obtained above for a simple column may be regarded as a statement that the equivalent masses of the liquid at the top and at the bottom of a simple adiabatic column are equal.

CONDITIONS FOR MINIMUM "REFLUX"

From the above equation for the mass ratio, $Z = \frac{M_A}{M_0}$, it follows that for fixed values of x_A, x_1, x_2, y_1, y_2 the maximum value of the ratio is obtained when y_0

*The first two articles in this series were published in the issues of Jan. 31 and Feb. 7, 1923.

is the least possible. If now, x_1 is less than x_0, it is clear that the minimum possible value for y_0 is the composition of a vapor having phase equilibrium with the liquid of composition x_0, since this liquid has previously been in contact with a vapor whose composition is less than y_0. If, on the other hand, x_1 is greater than x_0, then the minimum possible value of y_0 is that of a vapor having phase equilibrium with the liquids M_1 and M_0 combined. That is to say, if x_c is the composition of those liquids combined, the minimum possible value of y_0 is that of a vapor in phase equilibrium with a liquid of composition x_c.

We shall now ascertain the conditions existing in an adiabatic rectification column when, for a given mass, M_0 of "reflux" liquid entering the top, the maximum possible mass M_1 of a given composition x_1 is entering an intermediate point of that column, the end compositions x_1, y_1, x_2, y_2 being specified. Let us first suppose that the mass M_1 is added at a point in the column and in amount such that after it has been flowing steadily the composition x_0 at this level of the liquid descending from above is the same as the composition x_1 of that liquid i.e., $x_1 = x_0$. Under these conditions, let us determine for what composition $x_1 = x_0$ the ratio $Z = \frac{M_1}{M_0}$ is a maximum if such a maximum exists. If we place $x_1 = x_0$, our original expression for that ratio becomes:

$$Z = \frac{M_A}{M_0} = \frac{l_1L_2\,(x_0-x_1)\,(y_2-y_0)}{l_2L_1\,(x_2-x_0)\,(y_0-y_1)} - 1$$

That x_0 which makes the ratio Z a maximum must satisfy the equation $\frac{dZ}{dx_0} = 0$. From the equation for Z we obtain by differentiation:

$$\frac{dZ}{dx_0} = \frac{l_1L_2}{l_2L_1}\cdot\frac{(y_2-y_0)\,(y_0-y_1)\,(x_2-x_1) - (x_2-x_0)\,(x_0-x_1)\,(y_2-y_1)\dfrac{dy_0}{dx_0}}{(x_2-x_0)\,(x_0-x_1)\,(y_0-y_1)}$$

If, however, the ratio Z is a constant whatever be the value of x_0, then $\frac{dZ}{dx_0}$ must be identically 0. That is to say, the equation

$$\frac{dy_0}{dx_0} = \frac{(y_2-y_0)\,(y_0-y_1)\,(x_2-x_1)}{(y_2-y_1)\,(x_0-x_1)\,(x_2-x_0)}$$

with given end compositions x_2, y_2, x_1, y_1, must be an identity—i.e., it must be satisfied for all possible pairs of values of x_0 and y_0 connected by the relation $y = F(x)$ where F denotes the functional relation between x and y for phase equilibrium.

If we assume that x_2 and y_2 and also x_1 and y_1 are any two given pairs of compositions of liquid and vapor in phase equilibrium, the most general form of the functional relation between x and y in order for the last equation to hold for all possible pairs of values of x and y may be derived as follows: The equation for $\frac{dy_0}{dx_0}$ may in that case be regarded as a differential equation in which the variables are x_0 and y_0. It may be written in the form:

$$\frac{dy_0}{y_2-y_0} + \frac{dy_0}{y_0-y_1} = \frac{dy_0}{x_2-x_0} + \frac{dy_0}{x_0-x_1}$$

Integrating this, we obtain:

$$\log_e(y_0-y_1) - \log_e(y_2-y_0) = \log_e(x_0-x_1)$$
$$= \log_e(x_2-x) + \log_e$$

or

$$\frac{y_0-y_1}{y_2-y_1} = K\,\frac{x_0-x_1}{x_2-x_0}$$

where K is a constant for any (x_0, y_0) with given values of (x_1, y_1) and (x_2, y_2).

Since K in the last equation is a constant for any (x_0, y_0), it must be the same when $x_0 = y_0 = 0$ as when $x_0 = y_0 = 1$. In the first case, we have:

$$\frac{y_1}{x_1} = K\,\frac{y_2}{x_2}$$

and in the second case, we have

$$\frac{1-y_1}{1-x_1} = K\,\frac{y_2-1}{x_2-1}$$

or, by division:

$$\frac{\dfrac{y_1}{1-y_1}}{\dfrac{x_1}{1-x_1}} = \frac{\dfrac{y_2}{1-y_2}}{\dfrac{x_2}{1-x_2}}$$

Since, however, (x_1, y_1) and (x_2, y_2) are any pair of values satisfying the functional relation desired, we must have

$$\frac{\dfrac{y_0}{1-y_0}}{\dfrac{x_0}{1-x_0}} = a$$

where a is a constant for any (x_0, y_0) whatever—i.e.,

$$\frac{y_0}{1-y_0} = a\,\frac{x_0}{1-x_0}$$

is the most general form of the functional relation which makes the above equation for $\frac{dy_0}{dx_0}$ an identity.

This equation between co-existing liquid-vapor phase compositions is characteristic of those mixtures which in the liquid state have the properties of dilute solutions for which the heat of mixture is zero. (See Kuenen, "Theorie Der Verdampfung und Verflussigung von Gemischen," pages 127, 144-145.) This relation is satisfied approximately by a considerable number of two-phase binary liquid mixtures of the type having no maximum or minimum vapor pressure composition. In particular, it is satisfied approximately by liquid mixtures of oxygen and nitrogen, as we shall see later.

The above result shows that for a mixture satisfying this relation, the quantity of "reflux liquid," M_0 of a given composition necessary for a constant equivalent amount of the liquid M_A is constant—i.e., does not depend on the composition x_A of that liquid. We assumed in the above discussion that the composition x_A was identical with the composition x_0 of the liquid descending in the column at the point where the liquid M_A was added.

That, for given compositions x_1, y_1, x_2, y_2 of end products and for a given amount of "reflux" M_1, the amount, M_A, of liquid of a given composition x_A that it is possible to add at an intermediate level in the column is a maximum for this type of mixture when the condition $x_A = x_0$ is satisfied, may be shown as follows:

First assume that conditions are such that $x_0 > x_A$. Then the value of the ratio

$$\frac{M_A}{M} = \frac{l_1L_2}{l_1L_2}\,\frac{(x_0-x_1)\,(y_2-y_0)}{(x_2-x_A)\,(y_0-y_1)} - \frac{x_2-x_A}{x_2-x_0}$$

for given values of x_A and x_0 is the greatest possible

when the relation between x_0 and y_0 is that for phase equilibrium. With this value of y_0 the above expression for the ratio $\frac{M_A}{M_0}$ is a maximum when x_A is as large as possible. That is, x_0 and y_0 being fixed, that ratio is greater when $x_A = x_0$ than when $x_A < x_0$. But since when $x_1 = x_0$ the value of that ratio is independent of x_0, it follows that, x_1 being fixed, the ratio is greater when $x_0 = x_A$ than when $x_0 > x_1$.

Next assume that $x_0 < x_A$. Then the least possible value of y_0 is that for phase equilibrium with the combined liquids M_0 and M_A. If x_3 is the composition of this combined liquid, we have

$$x_3(M_0 + M_A) = x_0M_0 + x_AM_A$$

from which

$$x_A = (x_3 - x_0)\frac{M_0}{M_A} + x_3$$

Substituting this value of x_A in the equation

$$\frac{M_A}{M_0} = \frac{l_1L_2(x_0 - x_1)(y_2 - y_0)}{l_2L_1(x_2 - x_A)(y_0 - y_1)} - \frac{x_2 - x_0}{x_2 - x_A}$$

we obtain

$$\frac{M_1}{M} = \frac{l_1L_2(x_0 - x_1)(y_2 - y_0)}{l_2L_1(x_2 - x_3)(y_0 - y_1)} - 1$$

Now suppose that x_3 remains constant—i.e., x_A decreases and x_A increases in such a way as to maintain x_3 constant; then y_0 remains constant. But as x_0 increases, the ratio $\frac{M_A}{M_0}$ increases—i.e., the ratio when $x_3 = x_A = x_0$ is greater than when $x_0 < x_3 < x_A$. Since, however, when $x_3 = x_A = x_0$, the ratio is constant whatever be the value of x_0, it follows that for a constant x_A a maximum value of the ratio $\frac{M_A}{M_0}$ is obtained when $x_0 = x_A$.

In other words, for minimum reflux the liquid feed entering an intermediate level should be admitted in amount and at a level such that the composition of the liquid descending in the column has the same composition at that level as the entering liquid.

Example of Use of Preceding Formulas

As an example, let us consider the case where we are rectifying a liquid whose molecular composition is 40 per cent oxygen. Then $x_0 = 0.40$. The molecular composition of the vapor having phase equilibrium with the liquid is, according to Baly, 15.5 per cent; i.e.:

$$y_0 = 0.155$$

Let us assume that we obtain pure liquid oxygen at the bottom and pure nitrogen vapor at the top of the column. On this assumption, we have:

$$x_2 = y_2 = 1 \quad x_1 = y_1 = 0$$

For oxygen, $L_B = 51.15$ cal. per gram, or 0.0731 cal. per c.c., and for nitrogen, $L_1 = 47.85$ cal. per gram, or 0.0598 cal. per cc.

Substituting these values in the above equation between M_1 and M_0, we obtain:

$$M_A = 2.42M_1$$

or

$$M_1 = 0.413M_A$$

as the minimum relative amount of "reflux" liquid necessary. If the 40 per cent liquid is obtained by selective liquefaction of a gaseous mixture of nitrogen and oxygen, the percentages of which have the same ratio as those of ordinary air, the increase of the oxygen percentage of the liquid being obtained by withdrawing a residual gas composed of pure nitrogen during the process of liquefaction, then the amount of this pure nitrogen vapor available after liquefaction for use as "reflux" liquid may be calculated as follows:

Dry air contains, by volume, 21 per cent oxygen and 78 per cent nitrogen approximately, the remainder being mostly argon, carbon dioxide and hydrogen—i.e., the relative molecular percentages of oxygen and nitrogen in air are, say, 21 per cent oxygen and 79 per cent nitrogen.

Since the oxygen contained in the 40 per cent liquid is 21 per cent of the original gaseous mixture, all of this liquid is 21 ÷ 40 = 52½ per cent of the whole. Hence the pure nitrogen withdrawn during the formation of the liquid enriched in oxygen is 100 — 51½ = 47½ per cent of the whole.

The minimum amount of nitrogen necessary as reflux liquid, being 0.413 times as much as the liquid enriched in oxygen, will be 0.413 × 0.52½ = 0.217 of the whole. Hence there will be as surplus a maximum of 0.475 — 0.217 = 25.8 per cent of the whole as pure nitrogen not necessary for perfect rectification.

Continuation of this series of articles will be published in a subsequent issue.

Surface Oxidation During Hardening

One of the problems now being studied by the gage steel committee of the Bureau of Standards is the dimensional changes on hardening. To determine this, an accurate 4-in. cylinder 1 in. in diameter is measured and weighed both before and after hardening.

Surface oxidation may easily cause a scale to form thicker than the changes expected. If the scale is removed, some metal is lost and the change recorded is less than that due to hardening alone. The dimensional changes on hardening may be completely masked by the scaling effect. Coatings such as enamels, sodium silicate and electrodeposited silver have been tried in an effort to prevent oxidation in the air atmosphere of an electric furnace, but none was satisfactory under these conditions. However, by allowing illuminating gas to flow into the furnace at a rate just sufficient to burn the air leaking in, oxidation was apparently inhibited without disagreeable fumes from the furnace. Scale is then formed only during transfer to the quenching bath and is removed by cleaning with gasoline and pickling for a short time in cold 10 per cent H_2SO_4.

It was recently noticed that the 4-in. gage specimens, weighing about 400 grams, were losing from 0.5 to 1.0 gram in weight on hardening in this manner. To determine at what stage the loss occurred, a specimen was heated to 800 deg. C. as above, and after holding in the air for 5 seconds, was quenched in a small can of water so that the scale could be recovered. The weight of scale collected was 0.81 gram and the loss of weight of the specimen was 0.56 gram. On pickling 10 minutes the specimen lost 0.19 gram more, and on repeating the pickling only 0.01 gram, showing that the acid removes residual scale not flaked off during the quenching, but does not attack the metal seriously. This specimen increased in length by 0.0144 in. and in diameter by 0.000 in. on hardening, but before pickling. On pickling it lost 0.0004 in. in both length and diameter, which is evidently the thickness of the remaining oxide.

The total loss of 0.76 gram is equivalent to a layer of metal about 0.0004 in. thick over the whole surface or a loss of double that amount in length and diameter

Legal Notes

Of the Chicago Bar

Officers as Dual Agents

Presumption Against Validity of Transactions by Men Acting for Both Corporations

In a suit brought by the Mathieson Alkali Works against Arnold Hoffman & Co., Inc., the U. S. District Court in its opinion (280 Federal, 133) says that there is a strong presumption against the validity of transactions between corporations where conducted entirely through the agency of officers acting at the same time for both corporations, and the burden is on those who would maintain the transactions to show their entire fairness.

And a settlement or acceptance of accounts rendered requires independent representation to the party to whom they are rendered, and there can be no account rendered as between corporations where the transactions are conducted entirely through the agency of officers acting at the same time for both.

Again the court says that in a controversy between two corporations, when plaintiff corporation sought an accounting from defendant corporation, which was both a buyer and an agent for sale, with a limited agency, as in this case, the plaintiff is presumed to know what disposition was made of its own product and what it received for it from defendant, both as buyer and as sales agent. It is the duty of plaintiff, its officers and directors, to conduct its business with ordinary care, and the burden of explanation rests on it which cannot be sustained by a mere general claim that it confided implicitly in the defendant, so as to require the defendant to assume the burden.

Further, it says that when a business transaction is closed by an agent and his report is made thereon, the principal is charged with knowledge of what is reported, and cannot excuse himself from responsibility for action or inaction by continued reliance on one who is no longer a fiduciary as to completed transactions.

Langmuir Patent Again Upheld

Preliminary Injunction Granted Against Company Copying Tungsten-Nitrogen Lamps

Application of the General Electric Co. for a preliminary injunction against the Incandescent Products, Inc., was recently granted on the basis of the Irving Langmuir patent No. 1,180,159, owned by the former. This patent has been upheld in many cases and in various jurisdictions, and the court says ordinarily a patentee presenting such facts is entitled to a preliminary injunction on a showing of infringement. (280 Federal Rep. 856.)

The courts have written the history of the incandescent electric light lamps prior to the Langmuir invention. The Edison elements were three—a carbon filament, in a vacuum, inclosed in a glass chamber. These elements remained the same, with refinements, until Langmuir introduced into the art a co-ordination between a coiled tungsten filament in nitrogen, argon or mercury vapor gas, inclosed in a glass chamber under pressure.

The court says defendant's lamps are designed for use in the ordinary circuits. Those manufactured directly are rated at 150, 100 and 75 watts. The imported Austrian lamps sold by it are rated at 40 and 25 watts. There is in each a glass container with a coiled tungsten filament, filled with nitrogen gas under pressure. In the Austrian lamp the gas is a mixture of argon and nitrogen.

Defendant's Action Willful Disregard of Established Rights

There is nothing to distinguish defendant's lamps from the plaintiff's, as the entrance of the defendant into such business, after the establishment of the validity of the plaintiff's patent in another jurisdiction, indicates not only a slavish imitation but a willful disregard of established rights, says the court.

Defendant contended that the Langmuir patent is limited by the measure of the effectiveness and life of the lamps, as contrasted with those in which a vacuum was used. But the court points out that the patent was granted on a structure definitely described and clearly portrayed, the privilege being for the structure and not the result. It says it was a device, and not a result, which was patented, and the defendant can avail itself of nothing because in its manufacture the parts used by the Langmuir are so inartistically correlated as to produce a less efficient result.

Again, defendant called attention to the prior French patent La Tang No. 384,915 as an anticipation, and also to the Edison patent. But the court says the Langmuir patent having a tungsten filament in nitrogen gas was not infringed by prior patents for a vacuum tungsten lamp, or for a lamp having a carbon filament in nitrogen gas.

Sale of Element of Patented Combination Does Not Give Implicit License to Use Combination

More litigation involving the infringement of the Langmuir patent No. 1,180,159 is found in two separate suits in equity brought by the General Electric Co., against the Continental Lamp Works, Inc., and against the United Lamp Manufacturers' Corporation. (280 Federal 846.) Defendants admitted the validity of the patents, but denied infringement, claiming an implied license.

It appears that the General Electric Co., plaintiff, sold and continued to sell lamp bases for the lamp of the Langmuir patent to defendants after it knew or had reason to believe that the latter were using these bases in the manufacture of lamps infringing the Langmuir patent. Plaintiff contended that in making such sales it was not granting a license under the lamp patents, the contract of sale providing in red letters:

"The sale of bases by us confers on the purchaser no license under any patents of the General Electric Co. covering or relating to the structure of incandescent lamps, or the materials, machines or processes used in their manufacture."

Trial Court Held Plaintiff's Knowledge Implied License

Regardless of this, the defense contended that by reason of the purchase of the bases there was an implied license to use the lamps constructed under the Langmuir patent. The trial court upheld this contention and gave

judgment for the defendants, upon the theory that the bases which the plaintiff sold to them were sold with the knowledge that these manufacturers were making the lamps under an implied license from the plaintiff, General Electric Co., and that because the bases which were sold could be used only in constructing a patented article (Langmuir construction), it is presumed in law to be intended, by both the buyer and seller, to be used for that specific purpose, and when the plaintiff made a sale it carried with it to the defendants an implied license.

This decision was reversed by the United States Circuit Court of Appeals. It said the burden was upon the defendants to establish that the parties agreed, by a meeting of the minds, that the license contended for should be granted, or that when the bases were purchased the parties understood, and the defendants had adequate reason to assume, that they had received an implied license under the circumstances, which stopped the owners of the patent from denying that such was the intention of the parties at the time of the sales. And the court found the facts to be that there was nothing written or spoken from which a license was granted or might be implied.

Inventor Controls Terms for Use of Invention

Use of an invention can be obtained only on the inventor's terms. Without paying or doing whatever he exacts, no one can be exempt from his right to be excluded and, whatever the terms, the courts will enforce them, provided, of course, the licensee is not thereby required to violate some law outside of the patent law. On this point, in the case of United Nickel Co. vs. California Works, 25 Federal 475, the court said:

"The selling of the solution does not authorize, inferentially or otherwise, the use of it for the purpose of nickel-plating, whatever else it may be used for, without also procuring a license to nickel-plate under the first and fourth claims, which are separate inventions."

So where the owner of a patent sells a patented article subject to a restriction, the purchasers, with notice of this limitation, could acquire no better rights than strangers to infringe upon that part or claim of the monopoly still secured to the patentee. And the sale of an element of a patented combination does not necessarily imply license to use the whole combination. But there is always a question of what is a fair inference from the transaction.

In Edison Electric Co. vs. Peninsular Light Co., 43 C. C. A. 479, Judge Lurton pointed out that there may be circumstances under which the sale of a patented article by the patentee will carry with it the right to use another in co-operation with the first, although the thing be covered by a second patent, such as where an article of a peculiar construction is sold which has no practical use unless it be used in combination with some subordinate part covered by the patent of the vendor and the right to use the latter in co-operation with the former might be implied under the circumstances.

Rule of Law Covering Such Cases

The law was stated by Judge Lurton in these words: "The limitation upon this is that the things which pass by implication only must be incidental to the grant, and directly necessary to the enjoyment of the thing granted; the foundation of the maxim lies in the presumption that the grantor intended to make his grant enjoyable. . . . It is evident that the extent of an implied license must depend upon the peculiar facts of each case. The question in each case is whether or not the circumstances are such as to estop the vendor from asserting infringement."

In the case at bar this rule was applied. The court said that the mere sale imparts no license, except where the circumstances plainly indicate that it did, or except where good faith required, or where it cannot be doubted that the vendees understood that they were getting a license. In view of the red-lettered provision in the terms of sale, there was no justification for the vendees' assumption that they received a license under the patent. Neither conduct or language of the parties would justify the buyers of the bases in their use of the patented lamp in connection with same. The bases were capable of non-infringing uses, and the notice on its face was intended to warn against the use by infringement of the patent in suit. Therefore the lower court's judgment was reversed.

Breach of Implied Warranty

Federal Court of Appeals Holds Payment of Price Does Not Bar Action for the Breach

A question in sales law was presented in an action brought by the Lackawanna Steel Co. against the Herbrand Co. in the federal District Court, whose judgment was partly affirmed by the U. S. Circuit Court of Appeals. (280 Federal Rep., 12.)

Suit was brought for the price of a large quantity of steel bars sold to defendant, which counterclaimed for damages alleged for an asserted breach of implied warranty of fitness of a large amount of steel bars purchased in the previous year. The damages claimed consisted of the difference between the invoice value of the defective steel and its scrap value ($4,605.15), together with expenses incurred by plaintiff ($16,927.50) in manufacturing the defective forgings.

Plaintiff denied the claims of defendant. First, because defendant paid in full for the steel after it knew or should have known of the alleged defects therein. Second, because there was a general custom existing in the steel trade at the time whereby the manufacturer was not liable for the cost of labor or other expense incurred by the buyer in working defective steel, but that the latter's remedy with respect to reimbursement was limited to the replacement of the steel.

A verdict was directed upon the sole ground that defendant's right to complain of the defective steel was barred by its voluntary payment of the purchase price in full, with knowledge of the defects. It is a general rule of law that money voluntarily paid with full knowledge of the facts cannot be recovered.

Question of Waiver of Warranty Is a Question of Fact

But the Court of Appeals points out that an action for breach of warranty is not barred as a matter of law by payment of price. A retention of goods purchased and the payment of the price, or suffering the seller to recover a judgment therefore without defense and with knowledge of breach of warranty, does not as matter of law bar an action for the breach. The question of waiver of the warranty is at the most one of fact. Nor does retention of goods and payment bar an action for breach of warranty under the uniform sales act

as in force in Ohio. And while the extension of time granted for payment would furnish a good consideration for the waiver of action for breach of warranty, an extension does not as matter of law show such a waiver under the uniform sales act.

Now whether the defendant waived its right to damages under the circumstances of having paid without protest, etc., was a question of fact that should be left to a jury to decide.

Custom Limiting Liability Held Not Unreasonable

The custom in the steel trade as alluded to was established by witnesses, and this custom, under which the buyer's only remedy for defective steel was replacement or credit for its value, at the buyer's option, the seller not being liable for cost of labor or other consequential damage, the court held was not an unreasonable custom.

But the court said this custom did not forbid a recovery for failure to replace defective and unused steel, whose purchase price was greatly in excess of its scrap value; the seller being asked to replace such defective steel and having failed to make such replacement.

For error of the District Court in directing verdict for plaintiff in full of its claim the judgment was ordered reversed unless the plaintiff should remit from the judgment the sum of $4,605 15, covering the defective steel.

New Quenching Tank

Fig. 1 shows a quenching device recently designed by the W. S. Rockwell Co. The rectangular tank is filled to any desired depth with circulating oil or water. Heated metal parts of such size and shape as will permit

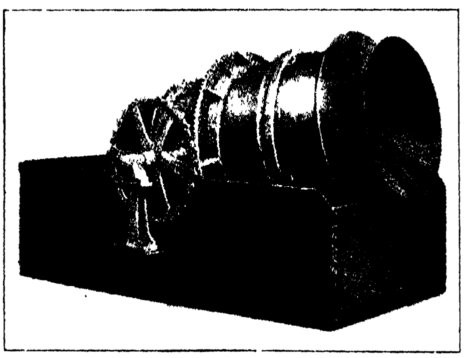

FIG. 1—ROCKWELL ROTARY QUENCHING TANK

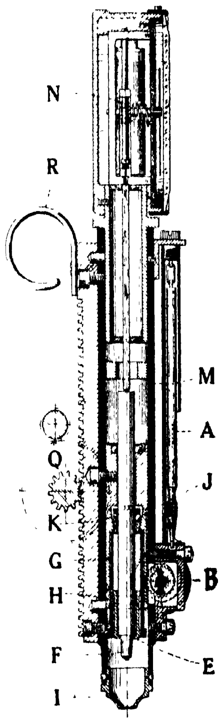
tumbling about are then dropped into the submerged end of the rotating drum. It is then automatically picked up in small batches by the internal thread of the rotating tank and conveyed through the quenching fluid as it is raised to the cone-shaped discharge spout. Naturally the device works best with a continuous flow of heated metal.

New Model Scleroscope

The problem of recording indications of the well-known Shore Rebound Reading Scleroscope Model C was solved by the use of a comparatively long hammer F, which, being much heavier, develops the same striking force by dropping only a short distance ($\frac{3}{4}$ in.). This principle is embodied in the "Model D Recorder." Although too complex to describe here at length, the hammer rebound is locked and recorded by means of a ball and hollow cone clutch. This clutch is made passive and active by raising balls in their retainer cage out of jamming contact with the hammer body, or putting them back to jam on downward pressure—no movement in this direction is then possible.

First Cycle (Second Period)

Thus when the hammer is ready to drop, its shoulder rests on the inner flange of the pilot sleeve E (see illustration), the upper end of which has just raised the ball cage G-J out of clutching contact. This bushing is held up by a hook.



MODEL D RECORDER

Upon releasing the hook, the hammer and its pilot sleeve E drop down together. The clutch having been left open, as it were, the ball cage remains up by friction of a band spring H.

The hammer strikes first, a moment later, the lower end the pilot sleeve E, which falls a little further, strikes the downward extending inner shoulder of the ball retainer sleeve G, instantly dropping them in jamming contact with the hammer. The movement of the ball cage sleeve is very short; the last part of its critical period, or just when the balls begin to touch the hammer body, is done at the moment the hammer is brought to momentary rest preparatory to rebounding.

The balls now in position do not retard the rebound but absolutely prevent a reverse motion, hence the slightest rebound is fixed positively and faithfully recorded.

Second Cycle

The hammer F, now locked firmly in the hardened cone sleeve K, the ball retainer G and pilot sleeve E are all raised up together by a rack and pinion by knob B to an upper stop Q. Here the pilot sleeve catches on its hook D and the hammer is brought in contact with the dial hand rack bar M, moving it to the extent of the recorded rebound. The spiral spring inside of the knob B then holds the clutch hammer and dial hand fixed until the next test is made.

First Cycle (First Period)

The turn of knob forward against its spring causes movements inside which constitute the first cycle. In the first period of this cycle the clutch sleeve, with its hammer still locked in it, is caused to descend. Soon the hammer contacts with the previously hooked up pilot sleeve E, where it remains on it as a standard height rest. As the clutch sleeve descends more, the ball cage contacts with the pilot sleeve, de-clutches the hammer and releases the hook so that they drop again for the second test (see first cycle, second period).

Synopsis of Recent Chemical & Metallurgical Literature

Manufacture of Blue Gas

James Hall, of Glasgow, Scotland, presented at a recent gas association meeting operating results from work at the gas plant of that city where thorough test of the efficiency of water-gas operation was made recently. This test was a 24-hour run with two Humphreys and Glasgow carburetted water-gas sets operated as blue-gas generators, using coke as fuel. The operating cycle was 1½ minutes blow, 1 minute up-run, 2 minutes down-run, and ½ minute up-steam run. Clinkering five times per set per day occupied from 15 to 50 minutes for a total of 6.16 hours out of the 24 operated. Some of the most interesting results are as follows:

Dry ash-free coke used per 1,000 cu ft of blue gas made . . . . . . 33.85 lb

Heating value of gas (gross). . . . . .296 B.t.u per cu ft

Composition of gas	
H	16.8
CH_4	1.1
CO	11.1
O	0.1
CO and H_2S	3.1
N	7.2
Composition of blue gas	
CO	9.0
O	Nil
CO	16.6
N_2	71.1

Further details can be found in *Gas Journal* (London), page 209, issue of Jan. 24.

Automatic Control of Water-Gas Sets

In the current (February) number of *American Gas Association Monthly*, C. H. Stevick presents a history of the development of automatic control of water-gas sets. The article also includes full description of the U.G.I thermal automatic control equipment, the Gas Machinery Co. type of equipment, and the Kennedy automatic control apparatus as made by the Bartlett-Hayward Co. The mechanism thus described is planned exclusively for water-gas apparatus operation, but the methods and apparatus would be adaptable to other types of automatic process control where periodic opening and closing of valves, lids, etc., is necessary. Chemical engineers having problems of this sort will find this review of the subject particularly pertinent.

Electroplating With Cobalt

A few years ago some Canadian research workers in the Canadian Department for Mines created considerable interest by putting forward a proposal to use cobalt as a metal for electroplating in the place of nickel. The results of these researches showed that cobalt could be deposited on brass, iron, steel, copper, tin, german silver, lead and britannia metal, and that the deposits were firm, adherent, hard and uniform, and could be readily polished to a satisfactory finished surface. The cobalt deposited was harder than the nickel and the speed of deposition considerably greater. It was also claimed that its resistance to corrosion was definitely superior to that of nickel, and that the deposits stood satisfactorily all the usual bending, hammering and burnishing tests. The actual weight of cobalt required for a good coating was stated to be about a quarter that of nickel. These claims have not, apparently, been entirely substantiated in British workshop practice, according to *The Engineer* (Jan. 12, 1923), but it is possible to electroplate with cobalt quite satisfactorily and very rapidly. It is considered by that publication unlikely that cobalt will ever attain the industrial importance of its sister element nickel, but it has a peculiar interest of its own, and exercises considerable fascination upon those who work with it.

Recent Chemical & Metallurgical Patents

American Patents Issued Jan. 30, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.*'s staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,443,359—Fuel and Manufacturing Process. Christian I Gillstrap, Iowa.

1,443,367—Apparatus for Dehydrating Fruit, Vegetables and Other Materials. Joseph E. Kennedy, New York.

1,443,381—Accelerating the Vulcanization of Rubber and Method of Producing the Same. Stanley John Peachey, Davenport, Stockport, England.

1,443,439—Process and Apparatus for Introducing Electric Energy Into a Space of Action. George T Southgate, Washington, D. C.

1,443,454—Process of Manufacturing Paper or Pulp. Lewis Miller Booth, Plainfield, N. J.

1,443,492—Apparatus for Determining the Relative Density of Two Gases. Ross F. MacMichael, Chicago, Ill.

1,443,538—Foam for Preventing Evaporation of Stored Liquids. Frank A. Howard, George H. L. Kent, James M. Jennings, Elizabeth, N. J.

1,443,547—Apparatus for Recovering Solvent. Arthur Samuel O'Neil, Springfield, Ill.

1,443,552—Esters of Trihalogentertiary Butyl Alcohol and Process of Forming Same. Thomas B. Aldrich, Detroit, Mich.

1,443,602—Preservative Composition. Max G. Weber, Newark, N. J.

1,443,616—Process for Separating Solids by Crystallization from Solvents. Henry Vincent Aird Briscoe, London, England.

1,443,618—Process of Making Coke. William Everard Davies, London, England.

1,443,674—Method for the Treatment of Silicates With Acid in Order to Obtain Saline Solutions Free From Silica. Gian Alberto Blanc, Rome, Italy.

1,443,697—Manufacture and Production of Tanning Agents. Robin Bruce Croad, Liverpool, England.

1,443,707—Roasting of Zinc Sulphide Ores, Preparatory to Leaching. Herbert W. Gepp, Melbourne, Victoria, Australia.

1,443,708—Roasting of Zinc Sulphide Ores, Preparatory to Leaching. Herbert William Gepp, Melbourne, Victoria, Australia.

1,443,714—Concentrating Process. Oliver Edward Merrell, Syracuse, N. Y.

1,443,735—Mixing Machine. Robert Edmondson, Rochester, N. Y.

1,443,742—Method of and Apparatus for Effecting Continuous Distillation. Francis M. Hess, Chicago, Ill.

1,443,743—Vapor Box or Still for Distillation Systems. Francis M. Hess, Whiting, Ind.

1,443,813—Enamel and Method of Making the Same. Alexander L. Duval D'Adrian, Washington, Pa.

1,443,816—Electric Furnaces. Francis A. J. FitzGerald, Niagara Falls, N. Y.

1,443,881—Fermentation of Cellulose. Herbert Langwell, Stockton-on-Tees, England.

1,443,935—Resinous Product. Louis Weisberg, Grantwood, N. J.

1,443,936—Process of Making a Molding Composition. Louis Weisberg, Grantwood, N. J.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Artificial Silk.—W. O. Mitscherling, of the Atlas Powder Co., Wilmington, Del., has been granted a patent covering a process for the preparation of viscose solutions of cellulose for the production of films or threads whereby the keeping qualities of the solution are improved, and at the same time the product is improved in quality. The ordinary carbon bisulphide viscose solution is quite unstable and gradually decomposes so that the mass sets to a solid jelly in about a week. This of course necessitates spinning before the setting takes place.

The process described in this patent is briefly as follows: The soda-cellulose is treated with carbon bisulphide to form the cellulose xanthate without aging the soda-cellulose and by using a weight of carbon bisulphide, which instead of being from 40 to 60 per cent of the weight of cellulose is only 30 to 32 per cent of that weight. The temperature does not have to be carried so low, the patentee recommending a temperature of approximately 20 deg. C. The cellulose xanthate formed is dissolved without aging in an alkaline solvent containing an amount of caustic soda so that the total amount of caustic soda is not less than the weight of the cellulose and not more by 2 per cent.

In connection with this patent, it will

be interesting to refer to British patent 183,882, which was granted to H. Dreyfus of London on Sept. 27, 1922, and which was abstracted in *Chem. & Met.* on p. 1138 of the issue for Dec. 6, 1922. (1,435,650. Nov. 14, 1922.)

Oil Treatment—An improvement in petroleum refinery methods, particularly as they relate to the washing of mineral oil, paraffine wax and other petroleum products, is described in a patent by Charles F. Kennedy, which has been assigned to the Atlantic Refining Co. of Philadelphia. The purpose of the washing, of course, is to improve the odor or color of the product or to render it non-emulsifying. Recourse is made to a suitably diluted solution of soap such as can be made by the combination of an alkali metal or ammonium salt with those organic or sulphonic acids found in ordinary acid sludge, such as results from the treatment of petroleum or petroleum distillates with strong or fuming sulphuric acid. Another and perhaps better source of these acids is the acid coke or tar which separates from the sludge.

Washing wax-bearing mineral oil or distillates prior to chilling and pressing is said to result in an improved crystalline structure of the wax formed upon chilling the oil, with resultant improved pressing qualities of the oil itself, better and more complete separation of the wax from the filter medium, an improved slack wax and a resultant improvement in the filtered oil.

Thus, in fractionating crude petroleum, as is indicated in Fig. 1, there is a residuum in the still which is heavy wax bearing oil, from which heavy or so-called cylinder lubricating oil may be produced. This residue may be washed with the soap solution previously referred to, and upon reducing its viscosity by the addition of naphtha or other low viscosity oil, it is chilled and the contained solids of the nature of petrolatum separate out more readily. In Fig. 2 is indicated one of the various forms of cracking distillation of crude petroleum, resulting in various cuts or products, any of which may be washed by the solution of sludge acid soap described in this patent. (1,439,171. Dec. 18, 1922.)

Dyes—A new yellow dye which is insoluble in water and in most organic solvents and for which is claimed superior fastness to washing, acids, chlorine and to light, is covered by a patent taken out by Georg Kalischer, Jens Muller and Detlev Nissen, all of Frankfort-on-the-Main, Germany, and assigned to Leopold Cassella & Co., Gaselschaft mit Beschrankter Haftung. This vat dye is prepared by heating methylanthraquinone with sulphur and aromatic compounds which contain the paradiamine-nucleus in their molecule. The paradiamines themselves such as benzidine, p-phenylenediamine and its substitution products are particularly well suited for the reaction. The quantities of the paradiamines of the compounds containing the paradiamine-nucleus may be varied considerably, but the proportion of 2 molecules 2-methylanthraquinone to 1 molecule paradiamine has proved particularly advantageous. The dyes yield olive to brown colored vats with hydro sulphites from which vegetable fibers are dyed greenish to reddish-yellow shades. The new dyestuffs are distinguished from those obtained by heating 2-methylanthraquinone with sulphur alone by their different chemical behavior and also by their superior tinctorial properties. (1,440,833. Jan. 2, 1923.)

Dehydration of Petroleum Emulsions—It is proposed to apply the principles of osmosis to effect a separation of water from emulsions of various petroleum products. In brief, the process consists of separating a body of the emulsion from a body of water by means of a porous diaphragm, and causing a direct current of electricity to flow between these two bodies. The water particles of the emulsion are caused to pass through the diaphragm by osmosis, thus dehydrating the emulsion. (1,440,835. Wynn Meredith, assignor to Petroleum Rectifying Co., of San Francisco. Jan. 2, 1923.)

Recovery of Phenol Vapor—Walter Runge and H. A. Curtis, of the International Coal Products Co., describe in two patents methods for recovery of phenol vapors evolved from solvent recovery processes or from other gaseous mixtures. The first of these patents proposes the use of phenolates, the second the use of suitable tar-oils, such as the material commonly known as "dead oil."

"When the sodium phenolate solution is made by neutralizing a sodium hydroxide solution of greater than 1.07 specific gravity the resulting sodium phenolate solution is miscible with tar acids in all proportions. It is feasible to employ this absorbing function of the sodium phenolate solution to ad-

FIG. 1.

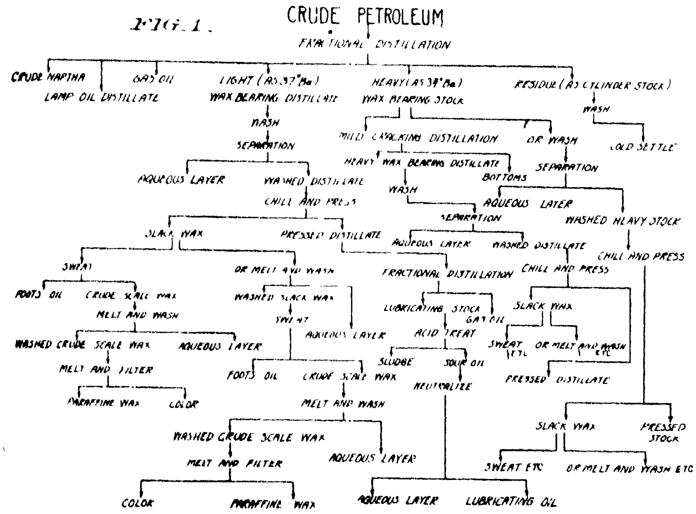


FIG. 1—A TYPICAL SCHEME FOR THE FRACTIONAL DISTILLATION OF CRUDE PETROLEUM

FIG. 2

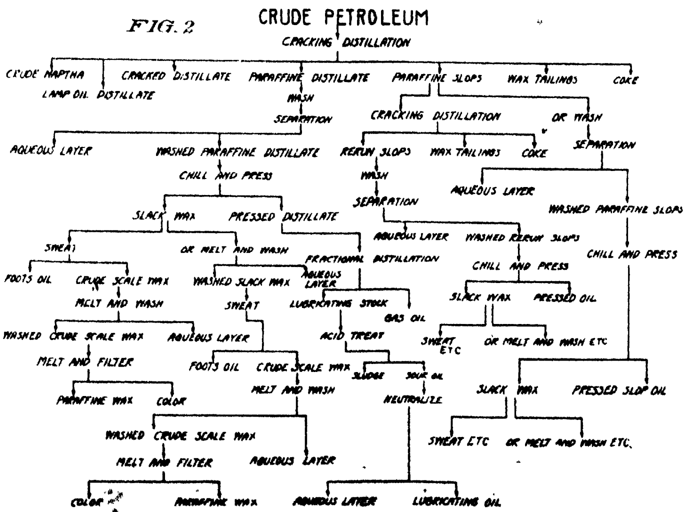

FIG. 2—DIAGRAMMATIC REPRESENTATION OF A TYPICAL CRACKING DISTILLATION OF CRUDE PETROLEUM

vantage in the recovering of the phenol-cresol-vapors from the gaseous mixture, and the present process employs the sodium phenolate solution of sodium cresylate solution—of the character specified—as the absorbing agent for the phenol or cresol vapors. The sodium phenolate solution picks up much less carbon dioxide from the air than would be the case with sodium hydroxide or caustic soda. The process may be employed as a continuous process or as an intermittent one."

The second patent, relating to the use of tar-oils, employs oils distilled from tar between 170 and 230 deg. C., preferably oils freed from tar acid.

Both patents are assigned to the Bregeat Corporation of America; and reference to this company's process is made in describing the invention. (1,439,128, 1,440,108, granted Dec. 19, 1922, and Dec. 26, 1922, respectively.)

Purification of Liquors Containing Phenol—Two recent patents, both assigned to the Koppers Co., Pittsburgh, relate to somewhat similar procedures for purification of waste liquor from ammonia stills of coke or gas plants and other waste liquor containing phenol which cannot be discharged to waste because of the damage done in streams, lakes or other water courses. The first of these patents, issued to Ralph L. Brown, relates to the use of certain phenol-destroying micro-organisms which are apparently of the bacterial type for the elimination of phenol apparently by oxidation to other unobjectionable compounds. The operation is conducted by passing the liquor through a filter of humus material properly activated by the presence of the suitable micro-organism. The other invention relates to the use of humus material for filtration with intermittent operation during which the humus material is used and then subsequently revived for re-use. (1,437,394 and 1,437,401, granted Dec. 5, 1922, respectively to Ralph L. Brown and to H. S. Davis and Saul D. Semenow.)

Anesthetic Compound—Roger Adams and Ernest H. Volwiler have patented a process of manufacture of the normal butyl ester of para-amino benzoic acid, an anesthetic compound which may be used locally, internally, for dusting on wounds and for anesthetic purposes in general. The compound is made by the reduction of the normal butyl ester of para-nitro benzoic acid. The latter is prepared by refluxing a mixture of para-nitro benzoic acid and butyl alcohol with a small amount of concentrated sulphuric acid for 8 hours. The reaction mixture is then distilled in a vacuum to remove the excess alcohol, the residue treated with dilute sodium carbonate solution, then extracted with ether, dried and distilled. After the ether has been removed, the residue is warmed up to vacuum for some time to remove the remainder of the normal butyl alcohol. The residue consists of fairly pure normal butyl ester of para-nitrobenzoic acid, which may be crystallized from petroleum ether. This nitro ester is mixed with powdered iron and 20 per cent of hydrochloric acid added gradually, the mixture being kept at about 50 deg. C. during the reduction. The reaction mixture is filtered, made alkaline with sodium hydroxide and extracted with ether. The compound may be crystallized from water or petroleum ether and has a melting point when pure of 57 to 58.5 deg. C. (1,440,652. Jan. 2, 1923.)

Commercial Fertilizer—E. A. Morgan, of Dorchester, Mass., has patented a commercial fertilizer which he claims is exceedingly beneficial. Primarily, it consists in the use of an appreciable percentage of finely ground sulphur in a dry mixed fertilizer. For example, 600 lb. of Canadian hard-wood ashes, 200 lb. of commercial crude potassium carbonate, 400 lb. of powdered sulphur, 400 lb. of sodium nitrate, 300 lb. of ground bone and 300 lb. of acid phosphate make up what might be called a typical formula. Sometimes when a less concentrated fertilizer is desired, a proportion of 5 parts of sifted soil or loam, ground wood, sawdust, etc., to 1 part of the formula is used. (1,440,836. Jan. 2, 1923.)

Method of Controlling Foaming of Boiling Liquids—C. E. Dolbear has assigned to the Industrial Research Corporation of San Francisco the following patent on preventing foaming in boiling liquids. Both petroleum and chlorine individually have some effect on the diminution of foaming, but the author has found that if the lighter boiling petroleum oils (the lighter oils prevent foaming which would be present in the heavier boiling fractions), the so-called "slop distillate" or "tops," are used in conjunction with chlorine (as the element or as chlorite or hypochlorite or other chlorine compound), the foaming is cut down by a very much greater amount. The author has used it particularly on potassium bearing brine. (1,440,973. Jan. 2, 1923.)

Vulcanizable Composition — W. E. Gardner, of Pittsburgh, has patented the following compositions which can be vulcanized to any degree of hardness or softness, depending on the time of heating. Twenty-five per cent of commercial rubber is broken down on the rolls to a consistency of thick molasses, and the following ingredients are incorporated with the rubber by sifting on to the roll: Sixty parts of fine Tripoli or its chemical or geological equivalent, 5 parts of sized mica, 2 parts of hydrated lime and 8 parts of sulphur. The compounding is then finished as usual on the roll and the sheets thus obtained can be treated in any way desired. (1,440,455. Jan. 2, 1923.)

Process and Apparatus for Treating Rubber—G. B. Britton assigned to the Firestone Tire & Rubber Co. a patent on a machine for drying rubber sheets. The washed sheet, thoroughly cleansed, is run through a pair of squeeze rollers and then into a small chamber, where it is treated with a blast of hot air from both sides. From this chamber it passes over a number of heated rolls, finally being wound up in convenient rolled form. It should be noted that the last roller is water-cooled, in order to prevent any bad effect from the rolling of the heated rubber. (1,440,371. Jan. 2, 1923.)

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Artificial Silk—In the manufacture of artificial threads from an unripened viscose employing an acid coagulating bath, the carbon bisulphide contained in the freshly precipitated acid threads is removed by treating the threads, without previous washing, with an alkaline bath. The threads may be in the form of hanks or layers of yarn, the bath may be maintained at 60 deg. C., and to it may be added a small quantity of sodium sulphide so as simultaneously to remove the sulphur; in that case, only a single washing is necessary. (Br. Pat. 187,942; not yet accepted. Glanzfäden Akt.-Ges., Petersdorf. Dec. 20, 1922.)

Chromium Compounds—Chromite is decomposed by treatment with sulphuric acid and an oxidizing agent, such as chromic acid, at a temperature above 150 deg. C., the oxidizing agent, whether added directly to the reaction mixture or generated *in situ* by electrolysis, being present in amount insufficient to oxidize the iron completely. The chromite may first be treated with carbonaceous matter or a gaseous reducing agent at a red heat and part of the iron then extracted with dilute acid. Under the conditions set forth above, the chromium and part of the iron are converted into insoluble sulphates, from which the chromium is separated by adding a reducing agent to the diluted reaction mixture when the ferric sulphate is reduced, leaving a residue of insoluble chromium sulphate. This compound may be decomposed by boiling in aqueous suspension with caustic alkalis or alkaline earths, alkali sulphides or carbonates, alkaline earth carbonates or ammonia to yield chromium hydroxide or basic carbonate; it may be heated with caustic soda or potash in presence of air and with the optional addition of other oxidizing agents to yield sodium or potassium chromate; or it may be boiled with strong barium chloride or acetate solution to yield the corresponding chromium salt and barium sulphate. Alternatively it may be dissolved in dilute sulphuric acid in presence of ferric oxide and a small amount of oxidizing agent and the solution, after reduction of any ferric salt formed, treated with potassium sulphate for the production of chrome alum.

Instead of first separating the insoluble chromium sulphate, the mixture of

insoluble chromium and iron sulphates obtained in the initial decomposition may be treated directly for the production of chromium oxide.

In one process the mixed sulphates are washed and heated with excess of coal in a reducing atmosphere, a mixture of iron sulphide and chromium oxide being obtained.

In another process, the mixed sulphates are boiled with a slight excess of alkali-sulphide solution and the black precipitate obtained ignited in a reducing atmosphere at red heat.

In a third process the mixed sulphates are calcined and the resulting oxides mixed with coal and heated in a reducing atmosphere.

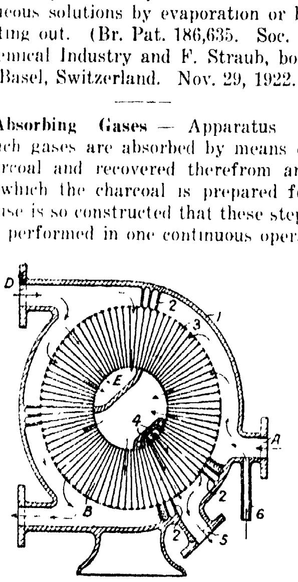
In each case the product is treated with acids to dissolve the iron, and the residual chromium oxide may be dissolved in sulphuric acid in presence of a small amount of oxidizing agent and used for the preparation of other chromium compounds. (Br. Pat. 187,636. C. K. Potter, St. Annes-on-Sea, and F Robinson, Bolton. Dec. 20, 1922.)

Dehairing Hides—Skins, especially those of rabbits, hares, kangaroos and opossums, are treated for the removal and recovery of the fur and hair without impairing the usefulness of the skins for the production of leather, by immersing them in a solution of sulphite of soda, then in a solution of ammonia, and finally subjecting them to a sweating process. The solution of sulphite of soda is of about 3 per cent strength, and the skins are soaked therein for about 12 hours to remove blood and fatty matter. The solution of ammonia contains about 4 pints of 880 ammonia in 4 gal. of water, and the treatment therewith is carried out in a closed vessel at a temperature of 80 to 120 deg. F. for about 12 hours. The skins are left in the sweating vat for 12 to 24 hours, the time varying according to the strength of the ammonia solution used and the temperature at which the sweating is carried out. The hair is then removed by scraping or brushing, which operation should be carried out as soon as possible after the removal of the skins from the sweating vat. (Br. Pat. 186,608; not yet accepted. G. Duckworth, Victoria, Australia. Nov. 22, 1922.)

Azo Dyes and Chromium Compounds—The chromium compounds of chromable azo dyes described in the parent specification are prepared by treating the dyestuffs in question in alkaline solution with the complex chromium compounds made by action of alkaline suspensions of chromium hydroxide on organic compounds containing more than one hydroxyl group. The process permits the use of iron vessels. According to examples: (1) the dyestuff from diazotized 1-amino-2-oxynaphthalene-4-sulphonic acid and α-naphthol, or that from diazotized 1-oxy-2-amino-4-methylbenzene-6-sulphonic acid and β-naphthol is refluxed with the product made by heating glycerine with caustic potash and chromium hydroxide paste; after diluting with water and neutralizing free alkali, the dyestuff is salted out; (2) the dyestuff from diazotized 1-oxybenzene-2-amino-4-chloro-6-sulphonic acid and 1-phenyl-3-methyl-5-pyrazolone is boiled with the chromium compound from gallic acid or glucose, the free alkali neutralized and the chromium compound salted out. The products dye wool blue, violet or red shades fast to light.

Complex chromium compounds of organic compounds containing more than one hydroxyl group are obtained by heating with alkaline suspensions of chromium hydroxide the parent compounds—for instance, polyhydric alcohols and phenols, tanning agents, sugars, degradation products of cellulose and waste products from sulphite cellulose manufacture; glycerol, glycol, glucose, tannin, gallic acid and phloroglucinol are mentioned. The compounds may in part be separated from their aqueous solutions by evaporation or by salting out. (Br. Pat. 186,635. Soc. of Chemical Industry and F. Straub, both of Basel, Switzerland. Nov. 29, 1922.)

Absorbing Gases — Apparatus in which gases are absorbed by means of charcoal and recovered therefrom and in which the charcoal is prepared for re-use is so constructed that these steps are performed in one continuous opera-



tion. The annular sieve drum 3 is subdivided by radial imperforate partitions into a series of narrow sectors containing charcoal, and the annular space between the drum 3 and the closed cylindrical casing 1 is divided by partitions 2. Gas entering at A passes radially through the charcoal, from which the absorbed constituents are recovered by rotating the drum so that sectors containing absorbed gas are subjected to the action of steam introduced from inlets 4. The mixture of steam and liberated gas leaves the apparatus at 5 for condensation and recovery, any residual gas being returned by the inlet 6. The gas originally introduced at A passes again through the charcoal at B, thereby cooling and drying the charcoal, and the gas having been cooled, it is passed again through the charcoal by means of the inlet D to complete the cooling process, and is finally withdrawn at E. The gas streams and the steam current may be applied axially instead of radially, and it is also stated that the system of supply pipes may be rotated. The apparatus is described with reference to the removal of benzene from illuminating gas. (Br. Pat. 187,223. Farbwerke vorm. Meister Lucius and Bruning, Hoechst-on-Main. Dec. 6, 1922.)

Desulphurizing Oils—Petroleum and similar oils are desulphurized by vaporizing the oil to convert the sulphur into sulphuretted hydrogen, and then treating the vapors with water or steam and a gaseous dissociating agent such as chlorine or sulphur dioxide, preferably under the action of a magnetic field. The vaporized oil, steam and dissociating agent are led into a chamber, packed with firebrick, pumice, etc., and surrounded by an electrical coil. The chamber is heated to 300 to 400 deg. C. In an example, the oil is vaporized, and the contained volume of sulphuretted hydrogen is determined. An equal volume of chlorine or sulphur dioxide and five volumes of steam at 240 deg. F. are then admitted. (Br. Pat. 186,738. W. R. Walkey, Westminster, and A. F. Bargate, London. Nov. 29, 1922.)

Food Products From Colloid Mill—Fruit, vegetables, etc., are made into colloidal dispersions in water or other liquid by a mechanical process such as that described in specification 155,836; undesired constituents may be precipitated and the solution concentrated or dried. When grapes are treated, the cellulose may be coagulated by boiling or by alcohol, which may be added or produced by fermentation. Apples may be treated and the juice freed from cellulose by boiling, mixed with sugar and evaporated to form a conserve. In treating beet, impurities may be coagulated by boiling and sugar separated in the ordinary way. Cacao beans may be treated and the solution heated to 60 to 80 deg. C. to coagulate cellulose, lignin, etc. The solution is concentrated by drying with or without sugar and a protective colloid such as gelatine or Iceland moss, and the dry product pulverized. (Br. Pat. 186,756. Plauson's, Ltd, London. Nov. 29, 1922.)

Hydrogen Peroxide—Hydrogen peroxide is distilled from solutions containing or yielding it by bringing the solutions into contact with the highly heated surface of a liquid or a fused salt, the evolved vapors being rapidly condensed. The liquid or fused salt employed is such that it can be heated, without boiling, to a temperature higher than the boiling point of the solution to be distilled, and this having been done, the solution is directed on to the heated surface either as a thin sheet or, preferably, as a spray; a stream of air may be sucked through the liquid to prevent sudden frothing. The preferred material for the heated surface is sulphuric acid or a fused bisulphate, and as examples of solutions which may be treated by the process, the following are mentioned: crude solutions of hydrogen peroxide, sodium, potassium, or ammonium persulphate, persulphuric acid and inorganic peroxides. (Br. Pat. 186,840. Woodlands, Ltd., Dover. Nov. 29, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Bureau of Mines Plans Ceramic Studies

Georgia Clays and Bauxites to Be Investigated in Co-operation With Manufacturers

In the course of the investigation of the kaolins, bauxites and feldspars along the right of way of the Central of Georgia R.R., being conducted by the United States Bureau of Mines at its ceramic experiment station, Columbus, Ohio, under a co-operative agreement with the Central of Georgia R.R., which was recently renewed for another year, the work is being grouped under three heads — whiteware clays, refractory clays and bauxites, and vitrified face brick.

In order to attempt the separation from the whiteware clays of certain deleterious materials, a semi-commercial centrifugal elutriation outfit has been devised by R. T. Stull, supervising ceramist of the Bureau of Mines, and set up at the Columbus station. With this outfit, about 1,000 lb. of clay is washed at one time. Seven clays have been so washed and seven more are still to be washed and tests made on the several separations. The clay washer has proved very satisfactory. The most highly purified material from the several clays burns to a white body free from specks.

Manufacturers to Co-operate

Five hundred pounds of the most promising of these clays will be sent to the Homer Laughlin China Co., at Newell, W. Va., where about eight hundred pieces of china are to be made in accordance with pottery practice. The behavior of these clays, as to working properties, color, percentage loss, etc., will be tabulated.

Some clays which are unsatisfactory for casting and jiggering can be used successfully in dry-press processes; so 500 lb. of one of the washed clays is to be made into tiles at the American Encaustic Tiling Co., Zanesville, Ohio, where this process is used.

Electrical porcelain is to be made from another of the clays at the plant of R. Thomas & Sons Co., East Liverpool, Ohio. The body which is best suited for this purpose is to be worked out and prepared at the station.

Proper dewatering methods will be studied in an endeavor to make both a saving in the time necessary to refine the clay and to improve its slaking properties. In this connection arrangements have been made to have some of the slips washed by the Bureau of Mines put through a Dorr thickener and continuous filter process. The Dorr Co. and the United Filters Corporation are co-operating in the work.

Preheating in order to improve the casting properties of these clays will be tried out, as a preliminary investigation has indicated that this property can be improved by such treatment.

Tests of Impure Bauxites

Great quantities of impure bauxites and bauxitic clays, which have been little utilized up to the present time, are being tested for their utility as material for refractories.

Bricks made from these clays and bauxites have been proved to have a higher fusion temperature than the best grade of firebrick, exceptional hot crushing strength and low spalling tendency. These properties, together with the large range of basicity obtainable in such refractories made from it, should insure a large application.

Tests are under way to prove whether it is not possible to use the same material for the bond as is used in the grog, since this would greatly cheapen manufacturing costs.

The bauxite grog is to be electrically sintered at the Seattle station of the Bureau of Mines. This grog is to be used in the electric furnace refractories.

Refractory Tests

The refractories are to be tested out in electric furnace practice, and bungs for malleable iron furnaces. The refractories are to be made at one of the plants of the Harbison-Walker Co., Pittsburgh, Pa. Mechanical strength, low spalling tendency and resistance to cinder abrasion are prime requisites for this type of refractory.

The electric furnace refractories are to be tested at the plant of the Bonney Floyd Co., Columbus, Ohio, in a Heroult furnace melting alloy steel. The requisites for such refractories are high fusion point and low slag penetration.

The bung brick, which have to withstand considerable heat together with sudden temperature changes, are to be tested at the plant of the Ohio Malleable Iron Co., Columbus, Ohio.

Large deposits of feldspar not sufficiently pure for pottery purposes exist along the right of way of the Central of Georgia R.R. These deposits can probably be utilized, together with some of the white clays, for making a semi-vitreous face brick. It is the purpose of the Bureau of Mines to run an investigation pursuant to the utilization of this material.

Chemical Products From Ruhr Cut Off by Occupation

Latest advices reaching Washington from the Ruhr indicate that practically all hope of any early shipments of chemical products from occupied Germany has been abandoned. Because of the exchange situation, however, it is believed that any stocks of chemicals in unoccupied Germany will be shipped to the United States in preference to other countries.

Manning Will Lead A.C.S. Motor Fuel Symposium

Motor fuels and substitutes will be the subject of discussion at a joint meeting of the gas and fuel chemists and petroleum chemists at the New Haven meeting of the American Chemical Society. Dr. Van H. Manning has consented to preside at this meeting and several well-known speakers will contribute important papers to the discussion. In addition to a résumé of present chemical knowledge in this field, some important new research results on several phases of the motor fuel problem will be included.

British Report on Transmission of Heat

A recent report of the Food Investigation Board of the British Government gives particulars of experiments carried out at the instance of the engineering committee of the board. The primary purpose was to obtain data which would be of assistance in investigations on problems of insulation connected with cold storage construction, but as the work progressed it became somewhat more general in character and a large number of the experiments were carried out as pure problems of engineering.

The process of the transfer of heat by convection of air has been exhaustively investigated, and it is said that the experiments throw new light on the mechanism of convection, especially in connection with the loss of heat from parallel vertical walls with an air space between. It is believed that these results will be of service not only in cold storage work but in various other departments of engineering.

House Approves Federal Sale of Nitrate

Recommends Adoption of Resolution to Authorize Government Sales of Fertilizer and Insecticide

With an amendment extending the period through the calendar year 1924 as well as throughout 1923, the House Committee on Agriculture has reported, with a recommendation for adoption, the Senate joint resolution authorizing and directing the President to procure stocks of nitrate of soda and calcium arsenate and to dispose of them at cost. The resolution also creates a $10,000,000 revolving fund for this purpose.

During and immediately after the war, nitrate of soda was purchased by the government and sold at cost to farmers under authority of the food control act. Charles J. Brand, who was chief of the Bureau of Markets of the Department of Agriculture at that time, testified before the House committee that during 1917 and 1918 120,000 tons of nitrate was purchased in Chile. Only 75,000 tons was received in time to be distributed during the season of 1918. Forty thousand tons of the 1918 purchases remained on hand and was sold in 1919, together with 113,000 tons declared surplus by the War Department and distributed by the Department of Agriculture, the total for the 2 years under this form of distribution being 228,000 tons. The testimony showed that the 1918 and 1919 nitrate deals of the Department of Agriculture involved about $20,000,000 and that the operations were conducted without loss and with a small fraction of 1 per cent gain.

Competition Among Nitrate Importers

B. M. Baruch, former chairman of the War Industries Board, and L. L. Summers, formerly a member of the Munitions Board of the Council of National Defense, told the House committee that competition among importers of Chilean nitrate has been keen and that there have been no evidences of combinations or price-fixing agreements.

The committee amended the Senate resolution to apply to 1924, because the reason when farmers purchase both nitrate and calcium arsenate is well advanced for this calendar year.

The report shows that government distribution of nitrate in 1919 represented sales in 38 states from 21 storage points. The normal quantity of nitrate of soda used for agricultural purposes in the United States annually is between 250,000 and 300,000 tons.

The report points out that white arsenic, which is chiefly a product of the copper smelters of the United States, is available only in limited quantities under existing circumstances.

The Department of Agriculture recommends the use of calcium arsenate as an insecticide for the control of the boll weevil. Its use for this purpose began only in 1919 and has increased so rapidly that the supply has not kept pace with the demand.

White arsenic is oxidized to arsenic acid under very carefully controlled conditions. The arsenic acid is then combined with hydrate of lime, both processes under very strictly controlled operation, and by the use of elaborate factory equipment, to produce calcium or lime arsenate. This careful preparation is of the utmost importance, as an improperly prepared product might readily kill a large number of plants.

In 1922 about 8,000 tons of calcium arsenate was sold and did not satisfy the demand. In the manufacture of this tonnage 3,600 tons of white arsenic was required. The probable minimum demand for the present and future seasons is about 12,000 tons of 2,000 lb.

Klein Explains Hoover Stand on Foreign Trade Zones

Criticism of Secretary Hoover's attitude on foreign trade zones and on the exemption from federal taxation of the income of American citizens engaged abroad has led Julius Klein, the director of the Bureau of Foreign and Domestic Commerce, to make the following explanation:

"The kind of products which are most likely to be imported into foreign trade zones for re-exportation are raw materials and certain types of bulk foodstuffs for which, under favorable conditions, we might become distributors. Such products are very largely of a non-competitive nature, many of them being on the free list of our tariff. Furthermore, they are produced, to a large extent, by tropical countries not possessing any considerable merchant marines. It is evident, therefore, that the creation of foreign trade zones could not possibly injure American industry, while, on the other hand, they are likely to benefit our shipping by enabling it to obtain return cargoes. Then, too, the benefit to be derived from free trade zones is not confined entirely to exemption from customs formalities, but is also due to the simplification of shipping regulations which make for a more economical utilization of merchant vessels.

Would Relieve Income Tax Burden

"With reference to the question of tax exemption, Mr. Hoover's proposal contemplates only the provision of relief for those incomes actually earned abroad in professional or trade activities by Americans resident overseas. At present they are compelled to pay in most instances a double income tax, to the United States and to the country in which they earn their income. In the World War states, this double taxation amounts to practical confiscation, and is rapidly driving American citizens out of representation of our commerce abroad. We are, therefore, confronted with the unpleasant prospect of entrusting our commercial interests abroad to the hands of foreigners, which is, of course, undesirable under all circumstances and decidedly dangerous. It is manifestly unjust, as it puts our citizens on a clearly unfavorable footing as against their rivals."

Representative Favors Ford Shoals Offer

Madden, of Illinois, Desires Matter Closed in Businesslike Manner —Has Confidence in Ford

Unqualified acceptance of Henry Ford's Muscle Shoals offer was proposed on Feb. 3 in the House, by Chairman Madden of the Appropriations Committee.

Representative Madden declared he viewed the matter purely from a business standpoint and that his desire was to put the great Alabama project in the hands of a man of demonstrated capacity, irrespective of his politics.

"I know of no person who has demonstrated a larger capacity to handle an undertaking of this magnitude than Henry Ford," declared the Illinois member.

Mr. Madden received an ovation as he concluded, many Democratic members from the Southern states being among those who rose to applaud him.

History of the Project

The appropriations chairman reviewed the whole history of the Muscle Shoals project and declared the issue had narrowed itself down to whether the government would spend another $100,000,000 in completing the dams and plants and putting them in operation or would turn the whole project over to Mr. Ford and receive a "substantial return" annually with a repayment at the end of 100 years of practically what it had spent under the Ford offer.

"We can't stop now," he said. "I feel we owe it to the taxpayers, the farmers and the nation to finish the operation. My own judgment is we should accept the Ford offer and get out of the business so as better to provide for the common defense in time of war and the welfare of the nation."

Pointing out that the government already had spent $107,000,000 on the project, Mr. Madden said estimates were that it would have to expend an additional $84,000,000 to complete it and get it into operation under government control. Under the Ford offer, he added, the government would have to put up another $50,000,000 to complete the dams and other work and then the demand on the Federal Treasury would end.

8 Per Cent Profit on Nitrate

For his part, Mr. Ford, he went on, would agree to operate nitrate plant No. 2 to its present capacity of 40,000 tons of nitrate annually, and in addition would keep the other plant fully equipped and ready for operation in the event of war. Profits on the sale of nitrate to the farmers would be limited to 8 per cent.

"Mr. Ford agrees to pay the government $5,000,000 for the project," he continued. "In addition he would have to put up $59,000,000 to get the whole works into operation, so he would not get such a wonderful bargain."

In concluding Mr. Madden said he had tried not to take sides in the matter but

to state "the plain, unvarnished facts," so that the House might draw its conclusions.

While Representative Madden's announcement that he regards it desirable for Congress to accept Henry Ford's Muscle Shoals proposition did much to stimulate the flagging hope of the advocates of that proposal, it apparently has brought the realization of those hopes no nearer.

It is admitted that this statement from such a prominent member of the House of Representatives is a great asset to the proponents of the Ford offer, but it is an asset which will be of more service in the next Congress than in this, since it is conceded that no vote can be had in the Senate at this session.

Coke Plants Plan to Install New Ovens

It is announced by the Columbia Steel Co. that a byproduct coke-oven plant of 33 new-type Koppers ovens will be constructed near Salt Lake City, Utah, for carbonization of Utah coal. This installation will have a carbonizing capacity of approximately 1,000 tons of coal per day. It will be the first plant installed to carbonize Utah coal in a coke oven.

An extension of the Republic Iron & Steel Co.'s Youngstown plant is planned to include a battery of 61 of the same type combination oven. This battery will be of the standard 12½-ton, 13¾-in. average width oven, designed to carbonize approximately 30 tons of coal per oven per day.

The small gas oven developed some time ago by the Koppers Co. is to be given practical plant trial through the installation of eleven 6¾-ton ovens for the Battle Creek Gas Co., Battle Creek, Mich. These ovens will be 13½ in. wide, designed for an average coking time approximately 12 hours, giving the plant a capacity of about 1½ million cubic feet of gas per day when fired with producer gas. The producer will utilize breeze and small coke and will operate in connection with a waste-heat boiler. Normally the plant will use producer gas for heating the ovens, but any individual oven or the entire battery may be changed over to burn coke-oven gas for oven firing if desired. The new oven corresponds in general type with that which has been tested out during the past year or more at the Chicago By-Product Coke Co. plant, with only such modifications as change in size make necessary.

Reviews Work of A.P.P.A.

Hugh P. Baker, executive secretary of the American Paper and Pulp Association, has opened a tour of the papermaking districts of the South and West, his first address having been delivered before the Virginia manufacturers at the Jefferson Hotel, on Feb. 6. He devoted his talk to a review of the work of the American Paper and Pulp Association, and made public a notable list of accomplishments of the association during the year just closed.

French Purchase of Haber Rights Approved by Deputies

The plan of the French Government to operate a fifty million franc nitrogen and synthetic ammonia plant and its agreement to purchase the rights of the Haber patent from the German Badische Anilin Co. today safely ran the gantlet of the anti-German criticism of members of the Chamber of Deputies, says an Associated Press dispatch dated Feb. 6. Government leaders were confident that Parliament would approve the proposed use of the enormous Toulouse gunpowder plant for the manufacture of fertilizers and gunpowder materials.

Louis Loucheur, former Minister of Reconstruction, was complimented for his success in negotiating for the Haber rights in 1919, for the option on which France paid 2,500,000 francs. The balance is to be paid when the factory is functioning normally. A French engineer has been for 9 months in the Badische Anilin plant watching the process of manufacture. Under the agreement France will be entitled to all developments in the process for 15 years. Under the plan the French Government will rent the Toulouse plant to a private corporation, but will subscribe for one-half of the stock.

Revised Winslow Bill Excludes Chemical Patents

Chemical Foundation Trusts Not Included in Those to Be Returned to Owners

A new bill which represents majority sentiment among the members of the House Interstate Commerce Committee has been introduced by Representative Winslow, to provide for the return by the Alien Property Custodian of certain trusts held by him under the trading with the enemy act. This measure will displace the one on the same subject which has been considered by the committee several months.

The revised bill, broadly speaking, provides for the return of trusts valued at less than $10,000, but no more than that maximum amount shall be returned to any one person regardless of the number of trusts in which he may possess an interest. A new provision is written in this bill stipulating that after its enactment dividends and interest on trusts still held shall be paid to the one for whom the trust is retained.

Excludes Foundation Patents

Exceptions to the bill are patents, trademarks and copyrights which have been "sold, licensed or otherwise disposed of" or which are involved in litigation "in which the United States, or any agency thereof, is a party." This exception excludes from the provisions of the bill all the patents given into custody of the Chemical Foundation, Inc., and all licenses under these patents and the patents previously issued by the War Trade Board, and also excludes various patents held by the War Department and the Navy Department.

The funds still to be held by the Custodian under the terms of the Knox-Porter peace resolution, together with several hundred million dollars worth of former enemy ships, will, in the opinion of administration officials, be a sufficient guarantee of American claims against Germany when adjudicated, although this administration has made it plain that it does not approve of confiscating the remainder of this property to pay these debts. This bill if enacted into law will provide:

1. For the return to their former owners of all trusts of the value of $10,000 and under, and a like sum to be returned to the owners of all trusts whose value exceeds $10,000.

There are approximately 28,000 trusts held by the Alien Property Custodian valued at less than $10,000 and approximately 2,200 trusts of the value of over $10,000; the total amount to be returned under this item alone will approximate $45,000,000.

2. On and after the passage of the act, all income accruing to the various trusts will be remitted by the Custodian to the former owners or their beneficiaries.
3. All patents that are not the subject of litigation, such as in the suit of the United States Government vs. the Chemical Foundation, Inc., or those that have been sold or assigned to the War and Navy Departments, will be returned by the Custodian.

This includes patents that are held by the Custodian and have not been sold, assigned or licensed by the previous administration to any government department or the Chemical Foundation.

4. Fugitives from justice are prevented from receiving any return of their property.
5. Another provision permits a corporation, partnership, or association to recover their property if their principal place of business is outside of Germany, Austria or Hungary and the majority of their stock is not owned by individuals of German, Austrian or Hungarian nationality.

This includes certain banks, corporations, etc., in those nations which formerly were a part of the Austro-Hungarian Empire, and those portions of Germany which are Polish or Danish territory, or Alsace or Lorraine, now French territory.

6. Extends power of the Custodian in deciding expatriation claims.

This relates to Americans or naturalized Americans who were caught in Germany or Austria at the outset of the war and whose property was seized and who have not satisfactorily explained or satisfied the State Department that they did not expatriate themselves.

No estimate has yet been prepared of the full effect of this bill as revised, Testimony before the committee by Alien Property Custodian Miller showed that there are 28,144 trusts held by that official valued at $10,000 or less each, the return of which would involve $22,122,002, leaving still in custody 2,224 trusts valued at $296,235,899.

Expect New Dye Customs Rules This Month

Special Deputy Appraiser of the Port of New York John Donnelly stated last week that tentative rules and regulations governing the customs appraisal of imported dyes may be issued by the Division of Customs, Treasury Department, prior to Feb. 15. The rules that will be issued will be of a temporary nature only and subject to change where such change may improve the method of ascertaining the tariff values of incoming dyes.

"We want importers and manufacturers to 'shoot' at these rules when they are issued," Mr. Donnelly declared. "This," he continued, "will enable us to perfect them from time to time in accordance with suggestions from interested parties."

The draft of the new rules, as prepared by the appraising officers at New York, were to have been submitted to the Treasury Department last week. It is believed that several days will be consumed by the Treasury in studying the draft as submitted and making any necessary changes. This means, it was explained, that the tentative or test rules will be in operation possibly on or about Feb. 15.

Canadian Experimental Farms Reports Busy Year

In the latest report of the work performed by the Division of Chemistry of the Dominion Experimental Farms in Canada during the past year, details and the results are given of the examination of 4,122 samples sent in for analysis from different parts of the country and including every province. Of these samples, 626 were of soils, 146 of manure and fertilizers, 597 of forage plants, fodders and feeding stuffs, 300 of waters, 2,190 samples of food products from the Meat and Canned Foods Division, and 263 under the head of miscellaneous, including dairy products, insecticides and fungicides.

The investigational work on soils for the Reclamation Service of the Department of the Interior, which was begun 2 years ago for the purpose of assisting in classification of the irrigable lands of southern Alberta and southwestern Saskatchewan, has been continued. The chief object of this work is the determination of alkali, enabling a report to be made upon the lands examined, as to their suitability or otherwise for cultivation under irrigation.

As required and in as far as circumstances permitted, analytical work and research was undertaken during the year for the several branches of the Department of Agriculture, the Post Office Department, the Department of the Interior, Department of Customs and Excise, Department of Marine and Fisheries, Department of Naval Service, and the several commissions and boards in connection with soldiers' civil re-establishment and settlement, so that the division acts as a bureau of chemistry for the entire government service.

New Laboratory Planned for Johns Hopkins

Plans for a new chemical laboratory for the Johns Hopkins University, to be erected at Homewood at a cost of about $600,000, have been completed. The details of the building have not been made public, but it is known that the type of architecture will conform to the Colonial style of the buildings in that group.

New Anode Alloy Cuts Copper Cost

Copper-Silicon Alloy Developed by C. G. Fink Reduces Anaconda Co.'s Costs to 6.4c. Per Pound

From the standpoint of technology, the most interesting and important portion of the annual report of the Anaconda-Copper Minning Co. is the following statement referring to electrometallurgical practice at Chuquicamata: "The solution is electrolyzed with a special copper-silicon anode which has greatly reduced the cost."

At this plant the solution for electrolysis is formed by leaching oxide ores containing about 1.8 per cent Cu with dilute sulphuric acid. In the electrodeposition of copper from such copper sulphate electrolytes ferrosilicon anodes (about 87 per cent Fe and 13 per cent Si) have been largely employed in commercial practice. Lead has also been used. The copper-silicon anodes referred to contain 15 to 25 per cent Si, 2 to 15 per cent Mn, 0.5 to 10 per cent Pb, 0.01 to 10 per cent Ba or Ca, with the remainder Cu.[1]

These have the advantage over ferrosilicon anodes that a normally lower voltage can be used and substantially no iron is introduced into the electrolyte by corrosion of the anode, whereas with ferrosilicon anodes a very considerable contamination of the electrolyte by introduction of iron takes place, and this contamination increases progressively with recirculation of the electrolyte.[1]

Long Life of Anodes

By avoiding such introduction of iron the copper-silicon anode materially decreases the cost of maintaining a low iron content in the electrolyte, since the electrolyte can be used for longer periods of time without requiring purification, thus reducing the acid lost with the impure electrolyte and reducing the amount of impure copper formed. As compared with the use of a lead anode, the copper-silicon anode presents the advantage of increased efficiency, particularly in electrolytes containing iron, inasmuch as lead anodes give extremely low current efficiency with such electrolytes unless special precautions are taken to keep the iron in the ferrous condition. The anode loss is materially less than with either ferrosilicon or lead anodes, with certain electrolytes, particularly copper sulphate electrolytes containing chlorides and nitrate. Owing to the relatively low cost of the anodes themselves in the first instance, and their resistance to breakage during handling and ordinary use, as well as their resistance to anodic disintegration, the process can be carried out for long periods of time, with resulting low cost of operation for the anodes, as well as with economy of operation in low voltage and power consumption and high current efficiency.

Reduction of Costs

Referring again to the annual report of the Chile Copper Co., the cost per pound of copper exclusive of interest, depreciation and depletion dropped from 10.8c. in 1921 to an average of 6.4c. in 1922. In 1915 the figure was 16.34c. Percentage recovery of copper has improved from 66.87 per cent in 1915 to 91.07 per cent in 1921. Present production rate is about 200,000,000 lb. per year, but further extension in the use of the new anodes will probably raise this to 225,000,000 lb. per year by May, 1923.

[1]See U. S. Patents 1,441,567 and 1,441,568, issued Jan. 9, 1923, to Colin G. Fink, assignor to Chile Exploration Co.

Paint Concern Restrained on Misbranding Charge

Misrepresentation in the advertisement and sale of paint was found by the Federal Trade Commission in the case of L. C. Orrell & Co., of Chicago, Ill. It developed in the commission's investigation that the company sold and offered for sale, through catalogs and other literature, ready mixed paints under the principal brand of "Painters' Pure Paint." This brand, the commission found, was represented as "100 per cent pure" and as composed of pure ingredients, whereas the fact was that substitutes comprised the principal component parts of such paints.

By specific terms of the commission's order, L. C. Orrell and Fredericka B. Orrell, co-partners in the Orrell company, are prohibited from using representations of "Painters' Pure Paint" brand or any other paint so offered and sold by respondents.

Chemical Tariff Rate Protests Will Be Heard First

Complaints against the chemical schedule of the new tariff act will be among the first to be investigated by the Tariff Commission, says a dispatch to the New York *Journal of Commerce*.

The commission expects to take up early next week the report of its advisory board with particular reference to the chemical schedule and investigations into costs of production as preliminary to public hearings which are to start shortly thereafter.

Lack of a quorum has delayed the commission in its plans to begin the preparation of recommendations to President Harding under the elastic provisions of the new law. Commissioner Edward P. Costigan is in the West and Commissioner William Burgess is ill, but is thought both will be ready to take up their duties next week.

Explosion Damages Helium Purification Plant

It was not an "explosion of helium" which damaged the purification plant at Langley Field, Va. In an official statement, R. B. Moore, chief chemist of the Bureau of Mines, declared that "there was no helium in the plant at the time of the accident and helium had absolutely nothing to do with the explosion." The accident took place when one of the liquefaction machines was being tested under air pressure.

The plant at Langley Field is intended to purify helium after it has been used in airships. There is some infiltration of air through the gas bag which must be removed periodically to maintain the lifting power of helium. It is for that purpose that the plant is being provided at Langley Field. It has no connection whatever with the production plant at Fort Worth and this accident has no bearing whatsoever on the general helium program.

Engineering Colleges Neglect Social Sciences

Federated American Engineering Societies' Committee Urges Broader Scope for Education

The colleges of the country are urged to "point engineers toward leadership in public affairs" in a report submitted to the Federated American Engineering Societies by its committee on industrial ideals, of which Prof. Joseph W. Roe, head of the department of industrial engineering at New York University, is chairman.

The report stresses the need of the engineer in public life, asserting that he must aid in removing the difficulties of the material world which he has created. Carrying out the idea expressed by Edwin Ludlow, past president of the American Institute of Mining and Metallurgical Engineers, that "this is an engineer's country but a lawyer's government," the report continues:

"For a century, engineers have directed their energy toward the utilization of the physical forces and the materials of nature. The developments which they have brought about have created an epoch in human history.

"While these developments have been of inestimable benefit and modern society could not exist without them, they have introduced many public problems and social readjustments so closely related to the engineer's activities that it is increasingly evident he must assume an active part in their solution.

Need for Public Service

"Recognizing this growing need, the engineers of the country formed the Federated American Engineering societies, primarily to place their knowledge and training at the public service on all public matters affecting engineering, or affected by it.

"Engineering education, reflecting closely the attitude of engineers heretofore, has confined its work almost exclusively to scientific and technical training, giving little if any attention to the social and human aspects of engineering enterprises.

"The Federated American Engineering Societies, therefore, speaking for the engineering profession, urges upon engineering colleges an increased attention to the social aspects of engineering activities and a broadening of their technical training in every way possible, to develop in engineering students the spirit of, and a capacity for, active leadership, not only in industry but in public affairs."

The other members of the committee, whose report has been adopted by the governing body of the Federation, are: Mortimer E. Cooley, dean of the engineering schools of the University of Michigan, Prof. C. F. Scott of Yale University and J. C. Ralston of Spokane, Wash.

Herty Optimistic on the Outlook for Industry

Tells Boston Meeting Ruhr Occupation Will Cut Off German Dyes, U. S. Will Not Notice It

An optimistic view of the present status of the American synthetic organic chemical industry was presented by Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers' Association, in a speech before the Northeastern Section of the American Chemical Society in Boston, Feb. 10.

"The economic struggle now in progress between France and Germany will, in all probability, result in the cessation of exports of German dyes and other synthetic organic chemicals, just as the blockade of German ports during the great war cut off all German chemical exports in 1916," said Dr. Herty. "It is very plain that with the Ruhr Basin isolated, thereby shutting off the coal needed for power and the essential raw materials, with transportation demoralized throughout the Rhine territory, which is the center of the dye and chemical industry in Germany, and, finally, with upset labor conditions as the result of French occupation, the crippling of the German chemical industry must necessarily follow, unless reparations questions are quickly settled by France and Germany."

Pre-War Conditions Changed

The blockade of 1916 found the American textile industry in a very embarrassing position, for there was then in this country barely a few months' supply of necessary colors, and no factories, or even a nucleus of an industry prepared to make dyes and chemicals. These facts are too well known to need repetition here. The American chemical manufacturer can justifiably point with pride to the condition which exists today, with an American synthetic organic chemical industry ready to supply practically the entire needs of the country. As a matter of fact, the American consumer would scarcely feel the result of the complete stoppage of German colors, so well has the American industry progressed during the 6 years of its existence.

Corn Products Acquires "Sealite" Rights

Newly Developed Substance for Preventing Oil and Gasoline Evaporation Was Perfected by Standard Oil Co.

Formal announcement has just been made that the Corn Products Refining Co. has acquired from the Standard Development Co., a Standard Oil subsidiary, control of all the rights of "Sealite," the newly developed preparation used to prevent evaporation of oil in storage and to minimize the danger from lightning. Negotiations have been under way for some time for the control of the product. The amount involved in the transfer was not made known.

Development of "Sealite"

The product "Sealite" represents the result of several years' research and development work by the technical staff of the Standard Oil Co. of New Jersey. The patents have been owned by the Standard Development Co. The product went into general use in the refineries of the Standard Oil Co. of New Jersey and its subsidiaries last year.

The principal constituents of "Sealite" — glucose, corn starch, glycerine, calcium chloride and glue—are produced by the Corn Products Co. at its various plants in the United States, and arrangements have been concluded to produce the "Sealite" itself at these plants so that it may be delivered to the petroleum refining and producing industry at a minimum cost.

Properties of Compound

It is explained that "Sealite" is a highly viscous fluid weighing approximately 4.75 lb. per gallon and having the appearance of a thick white paint. Although its viscosity increases at low temperatures, it flows freely down to 25 deg. F. It can be pumped, but only with great difficulty due to its high viscosity. Some of its constituents are of a drying character and some of a hygroscopic character, the proportions being so balanced that the material neither loses nor gains water upon exposure to the air. Tests and experience justify the conclusion that it is unaffected by atmospheric conditions.

It is chemically neutral, faintly sweet in odor and taste, non-poisonous, non-corrosive, and would be rated as non-combustible, although it decomposes under extreme temperatures, as do all organic materials. It is soluble in water in all proportions and insoluble in any petroleum oil in any proportion. It does not impart any color or odor to either crude or refined petroleum products. It is not subject to fermentation or decay.

New Society Formed to Champion Chemist

American Institute of Chemistry Will Devote Efforts to Promotion of Economic Status of Profession

The American Institute of Chemistry, an organization with the announced objects of aiding in the establishment of the professional status of chemists and promoting their economic interests, was formally organized on Feb. 5 in New York City. Constitution and bylaws were adopted and temporary officers elected.

The general purposes of the organization, as stated in the constitution, also include the compilation of a code of ethics and the promotion of popular appreciation of chemical research and control in the industrial field. The efforts of the Institute are to be devoted primarily to the interests of chemists rather than to the interests of the science. In a general way the functions of the new society will follow the model of the British and Canadian Institutes of Chemistry.

No Conflict With Present Societies

"It is not the intention of the Institute to encroach upon the fields of usefulness of the American Chemical Society, the American Electrochemical Society or the American Institute of Chemical Engineers," says a statement of the president, Horace G. Byers. "On the contrary, it earnestly seeks the co-operation of these agencies in their fields of usefulness with the efforts which the Institute will make in its own

"The Institute does not propose to enter the field of publication in any connection either directly or indirectly," continues the statement, "and it hopes to be mutually helpful to all the agencies of publication of chemical information which are now serving the public. The scientific papers presented at its meetings will seek publication in the present journals and every effort will be made by the Institute to co-operate with existing agencies for the benefit of the profession."

Its objects appeal naturally more strongly to the younger men, and development will doubtless be guided largely by their influence.

Temporary Officers

Temporary officers were elected as follows: President, Horace G. Byers; vice-president, Lloyd Van Doren; treasurer, Clarence K. Simon; secretary, Lloyd Lamborn.

Councilors were selected as follows: Ralph E. Lee, L. R. Seidell, F. D. Crane, L. W. Parsons, H. L. Lourie, Casimir Fink, L. J. Matos, Miss C. M. Hoke, Stanislaus Skowronski.

Membership of the new organization is to consist of fellows, associates and juniors. Fellows will comprise those who have had training equivalent to the B.S. degree in chemistry and a minimum of 5 years of experience. Associates must have the above educational training and juniors may be undergraduate students.

Personal

RICHARD V. AGETON, of the Bureau of Mines, who has been doing examination work for the War Minerals Relief Commission, is acting as assistant chief mining engineer of the bureau.

Prof. W. L. BADGER, professor of chemical engineering, University of Michigan, Ann Arbor, Mich., is taking a year's leave of absence beginning Feb. 1. He expects to continue his research work on evaporator design in Ann Arbor.

Dr. MARSTON T. BOGERT, professor of chemistry in Columbia University, gave a lecture at Connecticut College for Women, New London, Conn., on Jan. 23 on "Synthetic Dyestuffs and Their Bearing on the Life of the Individual and of the State."

HENRY T. CHANDLER, chemical and metallurgical engineer, has become connected with the Vanadium Corporation of America as metallurgical engineer, with headquarters at Detroit, Mich. He was formerly with the Ford Motor Co. as research engineer and more recently was connected with C. H. Wills & Co., Marysville, Mich., manufacturers of automobiles.

PERCIVAL CHRISTIE has been elected president of the Taylor-Wharton Iron & Steel Co., High Bridge, N. J., succeeding the late Knox Taylor. He has been vice-president and treasurer of the company for a number of years. Mr. Christie will also act as president of the William Wharton Co., Easton, Pa.; the Tioga Steel & Iron Co., and the Philadelphia Roll & Machine Co., both of Philadelphia, subsidiary organizations.

WIGGINGTON E. CREED, president of the Columbia Steel Corporation, Pittsburg, Calif., gave an interesting address on the progress of the steel industry at the weekly luncheon of the Down Town Association, San Francisco, on Jan. 25.

H. R. HANLEY has been appointed associate professor of metallurgy at the School of Mines and Metallurgy, Rolla, Mo.

Dr. ELLWOOD HENDRICK spoke at the Sterling Laboratory, before the New Haven section of the A.C.S., New Haven, Conn., Feb. 13, on "Obligations in Chemistry."

JOHN M. HOOD, JR., president of the Crown Cork & Seal Co., Baltimore, Md., has resigned.

HERMAN LIVINGSTON and PAUL MCMICHAEL, chemical and mechanical engineers, have opened an office in the Woolworth Building, New York City.

Dr. THOMAS MIDGLEY, JR., research engineer of the General Motors Research Corporation, has unfortunately contracted organic lead poisoning from his work on lead compounds used in preparing anti-knock motor fuels. Although Dr. Midgley's condition is not at all serious, he is on leave for an indefinite vacation to recuperate.

GEORGE SOUTHGATE has resigned from the Bureau of Soils, Washington, D. C., to accept a position with the Federal Phosphorus Co., Birmingham, Ala.

Dr. P. V. WELLS of the optics division of the Bureau of Standards, has resigned to take up research work for E. I. du Pont de Nemours & Co., Parlin, N. J.

Obituary

EVERETT C. BRITTON, an official of E. I. du Pont de Nemours & Co., Wilmington, Del., died at his local residence, Jan. 29, from pneumonia. He was 38 years old. His entire business career was spent with the du Pont organization, and for some time he acted as assistant to the director of the high explosives operating department.

DAVID COCHRANE, of the H. S. B. W. Cochrane Corporation, Philadelphia, Pa., the inventor, designer and first builder of the open-feed water heater which bears his name, died Jan. 24. Mr. Cochrane was born in Sawkey, Clackmanmonshire, Scotland, in 1850, and in his early years worked as a pattern maker on the Clyde. In 1879 he came to the United States, where he entered the employment of Ferris & Miles, but shortly afterward went with the Harrison Safety Boiler Works, then the builder of a sectional cast-iron boiler. His open heater, brought out in 1883, was specifically designed to protect boilers from the effects of cold, unpurified feed water, and was itself the first to be built of cast-iron plates, to avoid corrosion. Mr. Cochrane was also the first to design a successful oil separator, a heater and receiver, and other appliances which have since become standard practice. He was distinguished by great common sense in engineering matters and had a peculiar capacity for winnowing the wheat from the chaff and for simplifying construction. He was frequently consulted concerning the design of steam plants and his great contribution to steam engineering consisted in focusing attention upon the more efficient utilization of exhaust steam for heating buildings and for heating and purifying water to be used for feeding boilers and for industrial purposes. As early as 1894 he advocated the withdrawal of steam in course of expansion for feed heating and similar purposes, thus anticipating the present-day movement to provide all large turbines with bleeder connections.

What Shall We Do About Immigration?

Leaders in Commerce, Finance and Industry Contribute Their Opinions to Symposium of National Manufacturers Association—Recommend Changes in Law

PROBABLY no single economic question in this country is being so widely discussed at the present time as the fundamental problem of immigration. Current shortages of labor, particularly in the metal industries and building trades, have served to focus attention on our present immigration law and its operation under conditions that may be regarded as approximately normal.

In view of the timely importance of the subject, the National Association of Manufacturers recently sent out an inquiry asking a large number of representative men the question: "What shall we do about our immigration?" Forty-six responses were received from presidents of corporations, agricultural leaders, heads of great rail and water transportation systems, bankers, college professors, financiers and immigration specialists. The replies were practically unanimous in recommending that the present 3 per cent quota law be amended.

Constructive Suggestions

In addition the following constructive suggestions have been picked out as summarizing the recommendations most generally agreed upon:

The quota should be determined with the ultimate object of obtaining net immigration, and not according to the present method which in many instances causes a deficit of labor.

The Secretary of Labor should be authorized, on the presentation of satisfactory evidence of a shortage of labor in any industry, to bring about the admission of desirable immigrants to fill the special need.

A scientific selection of immigrants should be made by United States officers, on the other side of the ocean, so that intending immigrants who do not qualify may be rejected at the port of embarkation.

A centralized bureau or commission should be set up, so that all matters respecting immigration may be handled by it in the most expeditious, efficient and practical way.

The adoption of a more definite policy in the registration and distribution of the immigrants.

The nation should extend and make more humane its method of receiving immigrants.

A broader method of immigrant education is needed; one that will take him from the time of his entry and guide him properly for his naturalization.

Abolition of the literacy test.

Among those who contributed to the symposium were Judge Elbert H. Gary, W. W. Husband, Commissioner of Immigration; Frederick A. Wallis, former Immigration Commissioner at the Port of New York; Prof. Albert Shields, of Columbia University; Frederick Underwood, president of the Erie Railroad; Lee J. Eastman, president of the Packard Motor Co. of New York, and C. H. Markham, head of the Illinois Central system.

Legislative Proposals

It is interesting to know that the Immigration Committee of the House of Representatives is now considering and is reported to be in practical agreement on a tentative redraft of the present immigration law. It is suggested by the committee that the 3 per cent quotas based on foreign nationals resident in this country in 1910 be changed to 2 per cent on the basis of the 1890 census. This would have the effect of sharply reducing the allotted number of immigrants from Italy, Greece and southeastern Europe, but it is reported that other features of the bill will so liberalize the present law that at least 200,000 more aliens than are now permitted will be allowed to enter. This would increase the present maximum to about 550,000 per year, it is estimated.

To meet any shortages of skilled labor which may develop after the quotas are filled the Secretary of Labor would be authorized to admit workers in the groups needed when labor of like kind can not be found in America.

Aliens returning from temporary visits to their home lands, the number of which may likely run as high as 75,000 a year, are not counted in the quotas, as is now provided.

Broad exceptions are established for the foreign kin of American citizens or the close relatives of permanently admitted aliens.

Another exception includes immigrants who have resided for 5 years in contiguous territory, with their wives and children, provided they accompany them.

The Immigration Committee abandoned the idea of introducing the examination of aliens at the source, as well as the literacy tests.

However, in order to obtain a consular certificate required for entry the alien must fill out a form which in itself is a sort of literacy test.

February, 1922	148
February, 1921	166
February, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

As the result of a typographical error in our issue of Feb. 7, 1923, this index was reported as 175.08 for "last week" (Jan. 31, 1923) and the proper quotation for that week was omitted. Correct figures for this index since the first of the year are as follows:

Jan. 3, 1923	171.30
Jan 10, 1923	172.79
Jan 17, 1923	171.71
Jan. 24, 1923	174.21
Jan 31, 1923	175.15
Feb. 7, 1923	175.08
Feb. 14, 1923	175.64

Chemical Price Changes During January

Most of the price changes that occurred during January have not been of a fundamental character and in most instances were the result of current developments. The outstanding feature of the list was arsenic. The demand for calcium arsenate producers brought prices up from 15c. per lb. to 15½c. Bleaching powder was also advanced by leading producers to 2c. per lb. The resale market advanced from 2c. per lb. to 2¼c. Importers of caustic potash showed a strong tendency to increase quotations and prices recorded a net advance of 1c. per lb. during the month. Early in January quotations ranged around 6¼c. per lb. and during the latter part of the month prices advanced to 7¼c. per lb. Carbonate of potash also advanced from 5¼c. per lb. to 6c. Permanganate of potash showed a gain of 1½c. per lb. for the month. Quotations opened at 16c. per. lb. and gradually advanced to 17¾c. Producers announced an increase of 1c. per lb. on acetate of lead during January. Ammonium nitrate was sharply advanced due to the sold up condition of producers and the inability to import large quantities. Prices late in January were around 10¼c. per lb.

There were only a few declines. Oxalic acid, barium chloride, citric acid, red prussiate of potash, prussiate of soda and acetate of soda showed slight reductions during the month. The transportation situation has had a strong effect on many commodities. On the whole chemical prices have been well maintained and producers are confident that business will show material expansion in the next few months.

New York Chemical Market Lacks Important Features

But Few Significant Price Changes as Business Reflects an Unusual Lull —Shipping Conditions Improved

NEW YORK, Feb. 10, 1923.

Although on the surface the chemical market in New York City has been practically featureless during the past week, there is nevertheless abundant evidence that underlying conditions are fundamentally sound. The consuming trades continue their activity and the fact that there has been a temporary lull in buying does not necessarily mean that the consuming demand has been supplied.

The shortage of freight cars reported in these columns last week has been considerably relieved and as a result the alkali and heavy chemical producers are again able to make fair-sized shipments.

Arsenic and its compounds continue to be in demand and dealers are very firm in their belief that prices will reach much higher levels before spring. Lead arsenate has been advanced because of the strong demand from the insecticide trade. Importers of white sal ammoniac, sodium sulphide, lump potash, alum and sodium fluoride quoted fractionally lower prices in an effort to attract new business. Carbonate of potash, caustic potash, permanganate of potash, salt cake, prussiate of soda and bleaching powder continue along moderately active lines at former levels.

Principal Price Changes

Acetic Acid—The general tone was quite steady, with 28 per cent material quoted at $3.15 per 100 lb., carload lots. Glacial was held at $12 per 100 lb. in barrels.

Acetic Anhydride—Manufacturers announced lower prices for this material. The general range was around 36@38c. per lb. The demand, however, was somewhat unsteady.

Arsenic—Resale goods were reported firm at 15¾c. per lb. The general market is very strong, although a few odd lots are selling at slightly lower figures. Future shipments were held around 16c. per lb.

Barium Chloride—Leading importers offer spot goods at $90 per ton. Shipments quoted around $85. Domestic factors quote $95. Market rather irregular.

Bicarbonate of Soda—Producers quote the market around $1.75 per 100 lb. in barrels and $2 per 100 lb. in kegs, f.o.b. works. The general movement is of a routine nature.

Calcium Chloride—Manufacturers report transactions for the granular at 1½c. per lb. Fused material is quoted at $20@$21 per ton, f.o.b. works.

Carbonate of Potash—Imported material continues quite firm, with dealers quoting limited quantities of calcined 80-85 per cent at 6c. per lb. and 96-98 per cent at 7@7¼c. per lb.

Caustic Potash—Several fair-sized lots have been sold at 7¼@7½c. per lb. for the imported 88-92 per cent. Shipments are quite difficult to obtain below 7½c. per lb. c.i.f. N. Y.

Caustic Soda—Export business is without any special feature and prices for standard goods range around $3.45@$3.50 per 100 lb. Railroad shipments have been somewhat improved and consumers have been able to purchase at 3¾c. per lb. for prompt shipment. Contracts continue at 2½c. per lb., basis 60 per cent f.o.b. works.

Lead Arsenate—Producers report a very firm market, due to the increased demand from the insecticide trade. Sales of powdered recorded at 23c. per lb., with the paste at 12¾c.

Muriatic Acid—A slightly firmer market was noted for the lower grade and producers were not inclined to shade 90c. per 100 lb. for the 18 deg. acid in tank cars. The 20 deg. acid held at $1 per 100 lb.

Company Dividends and Financial Notes

Standard Oil Dividends. On Feb. 7 the Standard Oil Co. of Indiana announced a quarterly dividend of 62½c., which is an increase of $1 per year over the rate paid on its old stock prior to the recent 100 per cent stock dividend. The old rate was $4 a year; the new is $2.50, equivalent to $5 on the old stock.

On the same day the Imperial Oil Co., Ltd., of Canada, which is owned by the Standard Oil Co. of New Jersey, declared an extra dividend of $1 per share. If this is made a permanent quarterly feature the stock will be on a basis of $7 per year.

Ingersoll-Rand. The Ingersoll-Rand Co. has declared a quarterly dividend of 2 per cent on its common stock, payable March 1 to stockholders of record Feb. 17. This company had declared a 100 per cent stock dividend last December, prior to which time the quarterly rate had been 2½ per cent.

Eastman Kodak. The directors of the Eastman Kodak Co. recently declared the usual quarterly dividend of $1.25 a share and in addition an extra 75c. dividend on the common stock payable April 1.

American Hide & Leather Profits. The report of the American Hide & Leather Co. for the quarter ended Dec. 31, 1922, shows a net income of $294,875, which is equal to $2.35 per share on the $12,548,300 of preferred stock This compares with a net income of $268,209, or $2.13 per share, in the preceding quarter and $207,601, or $1.65 per share in the corresponding quarter of 1921.

In 1921 this company reported a deficit of $550,257, while in 1922 the net income amounted to $1,022,660. It should be pointed out, however, that the latter figure includes an extraordinary income for fire loss of $495,000.

Nitric Acid—Manufacturers report sales of the 36 deg. at 4½c. per lb. in carboys. Smaller lots command from 4½@5c. per lb. The 42 deg. test was held at 6c. per lb.

Prussiate of Soda—A slightly better tone was noted in this market and dealers were not inclined to shade 19c. per lb. for spot goods. Shipments from abroad held firm at 20c. c.i.f. N. Y.

Linseed and Cottonseed Oil Advance

The general tone of the market continued along very steady lines, due largely to the firmness in cottonseed and linseed oils. Most prices were unchanged, but dealers were quite certain that materially higher quotations would be seen before the spring season sets in.

Linseed Oil—Leading crushers announced another advance for February shipments, due to the pronounced scarcity of spot and nearby goods. Quotations range around 96c. per gal. Futures were advanced in proportion to the spot price.

Castor Oil—Prices showed practically no change for the interval, with AA quoted at 12¾c. per lb. and No. 3 at 12¼c. per lb. Demand continues along moderate lines.

China Wood Oil—Demand continued along very steady lines, with spot goods quoted at 18c. per lb. February-March shipments were held at 17½c. Nearby shipments from the coast in sellers' tanks were quoted at 15@15½c. per lb.

Satisfactory Business in St. Louis Market

Most Chemical Prices Are Firmly Maintained—Higher Alkali Prices in Prospect—Citric Acid Lower

ST. LOUIS, MO., Feb. 6, 1923.

A very satisfactory volume of business was transacted in this market during the month of January, and the activity has continued this month. The character of this business is very sound, which is accounted for by the firm market which has maintained for some time. Stocks in general are adequate, although a few articles are reported short in some directions. Transportation is still an obstacle confronting the shipper and very little improvement is expected before spring, as weather conditions during the winter months greatly hamper the operations of the railroads.

The chaotic condition in Europe has made no material change so far, but if the occupation of the Ruhr district is prolonged there will be a shortage of supplies of articles coming from this district, and consequently higher prices will be forthcoming.

Good Trading in Alkalis Reported

The market on alkalis continues firm, with a good volume of business being transacted. Prices have not changed, but a slight rise would not come as a surprise. *Caustic soda* is still being quoted at $3.90 per 100 lb. for the solid, and $4.25 per 100 lb. for the flake in 5-drum lots delivered to the buyer's door.

Quotations on carload lots would indicate about $3.40 per 100 lb. f.o.b. this market for the solid. *Soda ash*, 58 per cent light, is being quoted at $2.10 per 100 lb. in 5-bag lots, $2.30 per 100 lb. for 5 barrels. This has been shaded in one or two instances, but this price generally prevails. Carload lots sell around $1.55 per 100 lb. in bags f.o.b. shipping point. *Bicarbonate of soda* is holding firm and the best that can be done on less than carload quantities is $2.25 per 100 lb. on truckloads delivered. The 5-bbl. price is pretty generally $2.40 per 100 lb. *Sal soda* is in good demand at $1.55 per 100 lb. in barrels, $1.85 in kegs, $2 in cases—90 lb. in 2½-lb. packages.

General and Special Chemicals

Heavy mineral acids continue to move in good volume, particularly *muriatic*, and producers report being sold ahead over the next few months. Last week leading manufacturers announced an important reduction in the price of *citric acid* which was said to be due mostly to foreign competition. The reduction brought the price of crystals to 50c. per lb. and powdered to 51c. per lb., both in barrels, f.o.b. St. Louis, with the usual ½c. advance for kegs. *Citrates* remain unchanged, although citric acid declined. The demand for *tartaric acid* is nil, while *cream of tartar* has been more active. There are no special changes reported in *white arsenic*. Supplies are still very scarce and many users are buying as far ahead as 6 months so as to insure them of supplies when needed. *Carbon tetrachloride* and *bisulphide* are both moving in fair volume and remain unchanged in price. There is now a big demand for *creosotes* and *guiacols*. *Glycerine* continues in an unsettled state, and such a thing as an established market price does not exist—17@18½c. and anywhere between is considered a satisfactory price. *Cyanide of potash* is very firm, with a good demand. Red and yellow *prussiate of potash* are moving in larger volume. *Potassium permanganate* is very strong, with a good demand, and an advance in price in the very near future would not be surprising. *Sulphur* has not gained noticeable strength since our last report. A fairly good volume of business has not as yet brought about any strength in price, which continues very low. *Zinc sulphate* is quiet and very firm and the market is quoted at 3½c. f.o.b. St. Louis in carloads. *Zinc dust* is also quiet and firm with an increased inquiry, and the market is quoted at 10c. in carloads f.o.b. St. Louis.

Vegetable Oils and Paint Materials

Castor oil is maintaining its position of firmness attained a short time ago and a good volume of business is being done at 14c. in drums. *Turpentine* has declined sharply and is being quoted today at $1.43 in 5-bbl lots. *Linseed oil* has taken the expected advance, the prevailing price being $1.06 for the raw oil, $1.08 for boiled oil in single-barrel lots. In 5-bbl. lots a differential of 10c. per gal. prevails.

Advancing Tendency Continues in Steel Market

Increasing Strength the Result of Better Prices, More Business and Active Inquiry

PITTSBURGH, Feb. 9, 1923.

There is a still more pronounced advancing tendency in the steel market. In fact, the advancing tendency has been growing constantly since it first appeared about Jan. 1. Measured by prices, the steel market is stronger than ever. Measured by volume of business on books, it is likewise stronger than at any previous time in this movement. Measured by volume of inquiry, the market appears almost as strong as at any time. By still another symptom, the actual volume of sales and purchases, the market is decidedly quieter.

When the mills are not well sold up, inquiries and sales are much the same. When they are, the apparent volume of inquiry may greatly exceed the transactions, on account of many mills refusing to quote and an inquiry having to go the rounds before finding a seller, thus being magnified in apparent volume. A number of mills have been refusing more business than they have been accepting.

Production to Reach Maximum

Maximum steel production will probably be reached next month. Outputs have been increasing slightly in the past few weeks, with slowly increasing labor supply, due to intelligent employment effort, and with smoother operation of mills, from practice. March is almost always a month of high outputs, on account of weather conditions. After March labor shortage is likely to be a factor. A great deal of new construction is planned, and it is practically certain that not a few workmen will be drawn from mills by bonus wage rates.

Steel ingot production was at a rate of about 40,000,000 tons a year in each of the last 3 months of the old year. The rate has been increasing since December and it is far from improbable that a rate of close to 45,000,000 tons will be attained next month.

There is no particular scarcity of any finished steel commodity. The steel industry evidently has its old-time flexibility, with a finishing capacity well in excess of steel-making capacity, so that finishing departments can be operated in relation to the demands for the various products.

While no formal action seems to have been taken, it appears that the Carnegie Steel Co.'s price on shapes and plates has been advanced from 2.10c. to 2.20c. in the past week, following a definite advance in January from 2c. to 2.10c. The company's usual quotation on bars is 2.10c., but order books are so well filled that little tonnage can be taken. A large independent, on the other hand, is quoting 2.10c. on shapes and 2.20c. on bars. There is no single price quotable, much depending on tonnage, time of delivery and relation between mill and prospective buyer.

Late last week several independent pipe mills advanced prices two points on merchant steel pipe, three points on oil country goods and about $6 a ton on oil country goods. The Steel Corporation followed with similar advances. Nominally a point in merchant pipe discount is $2 a net ton, but on account of the trimmings it amounts to about $1.85. In the present advance one trimming, the last discount of 2½ per cent, was eliminated, so that the actual advance in merchant pipe averages slightly over $5 a net ton. The new basing discount is 64 per cent, the basing discount at the low point a year ago being 71 per cent. The total advance has been in the neighborhood of $15 a net ton.

For months past there has been some divergence in prices quoted on hoops and bands, according to width and gage. The divergence arose from the fact that with greatly advanced labor cost the old schedule of extras does not cover additional cost on the lighter material, weighing in some cases only a few hundred pounds per mile. Of late the irregularities have crystallized into two base prices, one, 2.75c., applying on bands and on hoops 1-in. and wider and 20 gage and heavier, the other, 3.50c., applying on lighter material. While this makes quite a difference between 20 and 21 gage, the mills are averse to tampering with established extras. A similar gap occurs between flats ¼-in. and $\frac{3}{16}$-in. respectively, the former being a bar and the latter a band.

Nearly all the independent sheet mills have now withdrawn from the market, being sold up to April 1 or later. These mills did not wish to fill up unduly prior to an advance in prices, but were not as ready as on former occasions to make formal announcement of advances. In a few cases mills have been quoting higher prices. It is taken practically for granted that prices will advance $3 or $5 a ton from the market level generally prevailing of late, 2.50c. for blue annealed, 3.35c. for black and 4.35c. for galvanized. Some mills have been disposed to increase the spread between black and galvanized from 1c. to either 1.10c. or 1.15c., on account of the high cost of zinc.

Coal and Coke

Market prices of Pittsburgh coal, Connellsville coal and Connellsville coke have declined slightly in the past week. In coal the decline is less than would be expected from the decreasing demand of the past few weeks, a supporting influence being car shortage, for car supplies in the Pittsburgh district have averaged decidedly less in the past 30 days than during December. Pittsburgh coal is now quotable at $2.75 for steam mine-run, $4.50 for nut and $4.25 to $5.00 for lump. Connellsville byproduct is quiet at about $3.50.

Demand for coke for heating purposes has been decreasing, but is still of fair volume. All prices are down about 50c. in the week, at $6.50@$7 for heating, $7.50@$8 for furnace and $8.25@$8.75 for foundry.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

Sodium bisulphate (niter cake)	ton	6 00 -	7 00
Sodium bisulphite, powd., U S.P, bbl	lb	04½-	04¾
Sodium chlorate, kegs	lb	06½-	07
Sodium chloride	long ton	12 00 -	13.00
Sodium cyanide, cases	lb	20 -	.23
Sodium fluoride, bbl	lb	.09 -	10
Sodium hyposulphite, bbl	lb	03 -	.03½
Sodium nitrite, casks	lb	08½-	09
Sodium peroxide, powd, cases	lb.	28 -	.30
Sodium phosphate, dibasic, bbl.	lb	03¾-	.04
Sodium prussiate, yel drums	lb	19 -	19½
Sodium silicate (40°, drums)	100 lb	80 -	1 15
Sodium silicate (60°, drums)	100 lb.	2 00 -	2 25
Sodium sulphide, fused, 60-62% drums	lb.	04 -	.04½
Sodium sulphite, crys., bbl...	lb.	.03½-	.03¾
Strontium nitrate, powd., bbl.	lb.	.09½-	.10½
Sulphur chloride, yel drums	lb.	.04½-	.05
Sulphur, crude	ton	18.00 -	20.00
Sulphur dioxide, liquid, cyl...	lb.	.08 -	.08½
Sulphur, flour, bbl	100 lb.	2.35 -	3.15
Sulphur, roll, bbl.	100 lb.	$2 00 -	$2.50
Talc—imported, bags	ton	30 00 -	40.00
Talc—domestic powd, bags	ton	18 00 -	25 00
Tin bichloride, bbl	lb	.11 -	11½
Tin oxide, bbl	lb	.45 -	.47
Zinc carbonate, bags	lb	14 -	.14½
Zinc chloride, gran, bbl	lb	.06 -	.07
Zinc cyanide, drums	lb	.38 -	.40
Zinc oxide, XX, bbl	lb.	.07½ -	.08
Zinc sulphate, bbl	100 lb	2.75 -	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl	lb	$0 80 -	$0.85
Alpha-naphthol, ref, bbl	lb	1 05 -	1 10
Alpha-naphthylamine, bbl	lb	27 -	.30
Aniline oil, drums	lb	16½-	.17
Aniline salts, bbl	lb	24 -	.25
Anthracene, 80%, drums	lb	75 -	1 00
Anthracene, 80%, imp, drums, duty paid	lb.	.65 -	.70
Anthraquinone, 25%, paste, drums	lb	70 -	.75
Benzaldehyde U S P, carboys	lb.	1.40 -	1.45
Benzene, pure, water-white, tanks and drums	gal.	.30 -	.35
Benzene, 90%, tanks & drums	gal.	.26 -	.32
Benzene, 90%, drums, resale	gal	.32 -	.34
Benzidine base, bbl	lb	.85 -	.90
Benzidine sulphate, bbl	lb	75 -	80
Benzoic acid, U S P, kegs	lb	72 -	.75
Benzoate of soda, U S P, bbl	lb	57 -	.65
Benzyl chloride, 95-97%, ref, drums	lb	25 -	.27
Benzyl chloride, tech, drums	lb	.20 -	.23
Beta-naphthol, subl, bbl.	lb	55 -	.60
Beta-naphthol, tech, bbl	lb	25 -	.26
Beta-naphthylamine, tech	lb	1 00 -	1.25
Carbazol, bbl	lb	.75 -	.90
Cresol, U S P, drums	lb	.25 -	.27
Ortho-cresol, drums	lb	.24 -	.26
Cresylic acid, 97%, resale, drums	gal.	1.60 -	1.75
95-97%, drums, resale	gal.	1 60 -	1.75
Dichlorbenzene, drums	lb	07 -	.09
Diethylaniline, drums	lb	.50 -	.60
Dimethylaniline, drums	lb	.40 -	.41
Dinitrobenzene, bbl	lb	20 -	.22
Dinitroclorbenzene, bbl	lb	.22 -	.23
Dinitronaphthalene, bbl	lb	.30 -	.32
Dinitrophenol, bbl	lb	.35 -	.40
Dinitrotoluene, bbl	lb	.22 -	.24
Dip oil, 25%, drums	gal.	.25 -	.30
Diphenylamine, bbl	lb	54 -	.56
H-acid, bbl	lb	.75 -	.80
Meta-phenylenediamine, bbl.	lb	95 -	1.00
Michlers ketone, bbl	lb	3 00 -	3.50
Monochlorbenzene, drums	lb.	.08 -	.10
Monoethylaniline, drums	lb.	95 -	1.10
Naphthalene, crushed, bbl	lb	.05½-	.06
Naphthalene, flake, bbl	lb	.06 -	.06½
Naphthalene, balls, bbl	lb.	.07 -	.07½
Naphthionate of soda, bbl	lb.	.58 -	.65
Naphthionic acid, crude, bbl.	lb.	.60 -	.65
Nitrobenzene, drums	lb.	.10 -	.12
Nitro-naphthalene, bbl.	lb.	.30 -	.35
Nitro-toluene, drums	lb.	.15 -	.17
N-W acid, bbl	lb.	1.15 -	1.20
Ortho-amidophenol, kegs	lb.	2.30 -	2 35
Ortho-dichlorbenzene, drums	lb.	.17 -	.20
Ortho-nitrophenol, bbl	lb.	.90 -	.92
Ortho-nitrotoluene, drums.	lb.	.10 -	.12
Ortho-toluidine, bbl....	lb.	.13 -	.15
Para-amidophenol, base, kegs	lb.	1.15 -	1.20
Para-amidophenol, HCl, kegs	lb.	1.20 -	1.25
Para-dichlorbenzene, bbl	lb.	.17 -	.20
Paranitraniline, bbl	lb.	.73 -	.75
Para-nitrotoluene, bbl	lb.	.55 -	.65
Para-phenylenediamine, bbl.	lb.	1.50 -	1 55
Para-toluidine, bbl.	lb.	.85 -	.90
Phthalic anhydride, bbl	lb.	.35 -	.38
Phenol, U S.P, drums.	lb.	.35 -	.37
Picric acid, bbl.	lb.	.20 -	.22
Pyridine, dom., drums	gal.	nominal	
Pyridine, imp, drums	gal.	3.00 -	3.10
Resorcinol, tech, kegs	lb.	1.50 -	1.55
Resorcinol, pure, kegs	lb.	2.00 -	2.10
R-salt, bbl	lb.	.55 -	.60
Salicylic acid, tech, bbl.	lb.	.40 -	.42
Salicylic acid, U.S P, bbl	lb.	.45 -	.47
Solvent naphtha, water-white, drums	gal.	.37 -	.40
Crude, drums	gal.	.22 -	.24
Sulphanilic acid, crude, bbl	lb.	.18 -	.20
Thiocarbanilide, kegs	lb.	.35 -	.38
Toluidine, kegs	lb.	1.20 -	1.30
Toluidine, mixed, kegs	lb.	.30 -	.35
Toluene, tank cars	gal.	.35 -	.37
Toluene, drums	gal.	.40 -	.43
Xylidines drums	lb.	.40 -	.45
Xylene, pure, drums	gal.	.45 -	.50
Xylene, com., drums	gal.	.40 -	.42
Xylene, com., tanks	gal.	.30 -	....

Naval Stores

Rosin B-D, bbl.......... 280 lb.		$5 75 –	...
Rosin E-I, bbl........... 280 lb.		5 90 –	
Rosin K-N, bbl. .... 280 lb.		6 10 –	$6 35
Rosin W.G.-W.W., bbl..... 280 lb.		7.75 –	8 25
Wood rosin, bbl.... ..... 280 lb.		6 25 –	
Turpentine, spirits of, bbl..	gal.	1 41 –	1 42
Wood, steam dist., bbl.....	gal.	1.35 –	
Wood, dest dist., bbl....	gal.	1.25 –	
Pine tar pitch, bbl ..200 lb		–	6 00
Tar, kiln burned, bbl....... 500 lb.		–	12 00
Retort tar, bbl. . ...500 lb.		... –	11.00
Rosin oil, first run, bbl. .. .	gal.	.43 –	.
Rosin oil, second run, bbl.. ..	gal.	.47 –	....
Rosin oil, third run, bbl...	gal.	.53 –	...
Pine oil, steam dist.	gal.	... –	.90
Pine oil, pure, dest. dist... .	gal.	.... –	.85
Pine tar oil, ref . .	gal.	.... –	.46
Pine tar oil, crude, tanks f.o b. Jacksonville, Fla...	gal.	.... –	35
Pine tar oil, double ref , bbl .	gal.	..... –	.75
Pine tar, ref., thin, bbl	gal.	..... –	.25
Pinewood creosote, ref , bbl	gal.	...... –	.52

Vegetable Oils

Castor oil, No 3, bbl	lb	$.12½–	$.12¾
Castor oil, AA, bbl.	lb.	.12½–	.13
Chinawood oil, bbl. .. .	lb	.18 –	18½
Coconut oil, Ceylon, bbl... .	lb	.09¼–	.9½
Coconut oil, Cochin, bbl... .	lb	.09½–	10
Corn oil, crude, bbl. .	lb	.11½–	.11¾
Cottonseed oil, crude (f.o.b. mill), tanks ..	lb	.09¾–	.10
Summer yellow, bbl	lb.	.12½–	12¾
Winter yellow, bbl.	lb	.13 –	13½
Linseed oil, raw, car lots, bbl	gal.	.96 –	97
Raw, tank cars (dom) ..	gal.	.92 –	93
Boiled, 5-bbl lots (dom.)	gal.	1 00 –	1 02
Olive oil, denatured, bbl . .	gal.	1 00 –	1 15
Palm, Lagos, casks	lb	08 –	08½
Palm kernel, bbl	lb	08¾–	09
Peanut oil, crude, tanks (mill)	lb	13½–	13¾
Peanut oil, refined, bbl	lb	16 –	16½
Rapeseed oil, refined, bbl .	gal.	.85 –	86
Rapeseed oil, blown, bbl	gal.	.90 –	.91
Soya bean (Manchurian), bbl.	lb.	.11½–	..
Tank, f o b. Pacific coast	lb	10 –.	.

Fish Oils

Menhaden, light pressed, bbl	gal	$0 60 –	.
White bleached, bbl	gal	64 –	65
Blown, bbl	gal	.68 –	69
Whale No. 1 crude, tanks, coast	lb	.06 –	06½

Dye & Tanning Materials

Divi-divi, bags	ton	$38 00	$39 00
Fustic, sticks ...	ton	30 00 –	35 00
Fustic, chips, bags	lb	04 –	05
Logwood, sticks .	ton	28 00 –	30 00
Logwood, chips, bags.	lb.	02½–	03½
Sumac, leaves, Sicily, bags...	ton	65 00 –	
Sumac, ground, bags. . .	ton	55 00 –	60 00
Sumac, domestic, bags.. ...	ton	35 00 –	
Tapioca flour, bags. ..	lb	.03½–	.05

EXTRACTS

Archil, conc , bbl.......	lb.	$0 17 –	$0 18
Chestnut, 25% tannin, tanks	lb	02 –	03
Divi-divi, 25% tannin, bbl	lb.	04 –	05
Fustic, crystals, bbl	lb	20 –	22
Fustic, liquid, 42°, bbl .	lb.	.08 –	09
Gambier, liq , 25% tannin, bbl.	lb	.08 –	09
Hematine crys , bbl. . .	lb	14 –	18
Hemlock, 25% tannin, bbl	lb.	04 –	.05
Hypernic, solid, drums .. .	lb	.24 –	26
Hypernic, liquid, 51°, bbl....	lb	14 –	.17
Logwood, crys., bbl	lb.	19 –	.20
Logwood, liq , 51°, bbl..... .	lb.	.09 –	.10
Quebracho, solid, 65% tannin, bbl.	lb.	.04½–	05
Sumac, dom , 51°, bbl. . .	lb.	.06½–	.07

Waxes

Bayberry, bbl . .	lb.	$0 28 –	$0 30
Beeswax, refined, dark, bags	lb	.30 –	.32
Beeswax, refined, light, bags..	lb	.34 –	35
Beeswax, pure white, cases.	lb.	.40 –	41
Candellila, bags .	lb	.34 –	.35
Carnauba, No 1, bags	lb	.38 –	40
No 2, North Country, bags	lb.	.24 –	24½
No 3, North Country, bags	lb	.17½–	18½
Japan, cases	lb	.15 –	15½
Montan, crude, bags..	lb.	.03½–	04
Paraffine, crude, match, 105-110 m p . ..	lb.	.04 –	04½
Crude, scale 124-126 m.p., bags	lb.	.02½–	02¾
Ref., 118-120 m.p., bags	lb.	.03¼–	03½
Ref , 125 m p , bags . .	lb.	.03½–	.03¾
Ref. 128-130 m p , bags . .	lb	.04 –	04¼
Ref , 133-135 m p , bags	lb.	.04½ –	04¾
Ref , 135-137 m p , bags	lb	.05 –	05½
Stearic acid, sgle pressed, bags	lb.	10 –	10½
Double pressed, bags. .	lb.	.10½–	.10¾
Triple pressed, bags .. .	lb.	.11 –	.11½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works .... 100 lb.		$3.20 –	$3.25
F.a.s. double bags...... 100 lb.		3.85 –	3.95
Blood, dried, bulk..........	unit	4.60 –	......
Bone, raw, 3 and 50, ground..	ton	30.00 –	35.00
Fish scrap, dom., dried, wks..	unit	5.00 –	5.10
Nitrate of soda, bags...... 100 lb.		2.60 –	2.65
Tankage, high grade, f.o.b. Chicago...............	unit	4.70 –	4 80

Phosphate rock, f o.b. mines, Florida pebble, 68-72%....	ton	$3.50 –	$4 00
Tennessee, 78-80% .	ton	7 00 –	8 00
Potassium muriate, 80%, bags	ton	35 00 –	36.00
Potassium sulphate, bags	unit	1.00 –	......

Crude Rubber

Para—Upriver fine	lb.	$0 33½–	$0 34
Upriver coarse .	lb.	27½–	28
Upriver caucho ball	lb.	.29 –	.29½
Plantation—First latex crepe	lb	35½–	35¾
Ribbed smoked sheets	lb.	.35½–	.35¾
Brown crepe, thin, clean	lb.	31 –	.32
Amber crepe No 1 .	lb.	.31 –	.32

Miscellaneous Materials

Asbestos, crude No 1, f o b., Quebec	sh. ton	$450 00 –	$550.00
Asbestos, shingle, f o b , Quebec	sh ton	60 00 –	80 00
Asbestos, cement, f.o b , Quebec	sh. ton	15 00 –	17 00
Barytes, grd , white, f o b mills, bbl	net ton	16 00 –	20 00
Barytes, grd , off-color, f.o b. mills bulk .	net ton	13.00 –	21.00
Barytes, floated, f.o b St. Louis, bbl .	net ton	24.00 –	28 00
Barytes, crude f.o b mines, bulk	net ton	8 50 –	9 00
Casein, bbl , tech	lb.	.11 –	12
China clay (kaolin) crude, f o b Ga.	net ton	7 00 –	9 00
Washed, f o b Ga	net ton	8 00 –	9 00
Powd , f o b Ga	net ton	13 00 –	20 00
Crude f o b Va .	net ton	8 00 –	12 00
Ground, f o b Va..	net ton	13 00 –	20 00
Imp , lump, bulk.	net ton	15 00 –	20 00
Imp , powd	net ton	45 00 –	50 00
Feldspar, No. 1 pottery...	long ton	6 00 –	7 00
No. 2 pottery .. .	long ton	5 00 –	5 50
No. 1 soap	long ton	7 00 –	7 50
No. 1 Canadian, f o b mill	long ton	25.00 –	27 00
Graphite, Ceylon, lump, first quality, bbl	lb	.06 –	.06½
Ceylon, chip, bbl	lb	05 –	05½
High grade amorphous crude	ton	35 00 –	50 00
Gum arabic, amber, sorts, bags	lb	.15 –	16
Gum tragacanth, sorts, bags	lb	50 –	60
No 1, bags	lb	1 75 –	1 80
Kieselguhr, f o b Cal .	ton	40 00 –	42 00
F o b N Y	ton	50 00 –	55 00
Magnesite, crude, f o b Cal	ton	14 00 –	15 00
Pumice stone, imp , casks	lb	03 –	05½
Dom , lump, bbl	lb	05 –	05½
Dom , ground, bbl	lb.	.06 –	07
Shellac, orange fine, bags	lb	83 –	84
Orange superfine, bags	lb	85 –	86
A C garnet, bags	lb	80 –	81
T N , bags	lb	81 –	82
Silica, glass sand, f o b Ind	ton	2 00 –	2 50
Silica, sand blast, f.o b Ind	ton	2 50	5 00
Silica, amorphous, 250-mesh, f o b Ill	ton	17 00 –	17 50
Silica, bldg sand, f o b Pa	ton	2 00 –	2 75
Soapstone, coarse, f o b Vt , bags	ton	7 00 –	8 00
Talc, 200 mesh, f o b , Vt , bags .	ton	6 50 –	9 00
Talc, 200 mesh, f o b. Ga , bags .	ton	7.00 –	9 00
Talc, 200 mesh, f o b. Los Angeles, bags.	ton	16.00 –	20.00

Refractories

Bauxite brick, 56% Al_2O_3, f o b. Pittsburgh .	ton	$45–50
Chrome brick, f o b. Eastern shipping points .	ton	50–52
Chrome cement, 40-50% Cr_2O_3.	ton	23–27
40-45% Cr_2O_3, sacks, f o b. Eastern shipping points.. .	ton	23.00
Fireclay brick, 1st quality, 9-in. shapes, f.o.b Ky wks..... .	1,000	40–46
2nd quality, 9-in. shapes, f o b. wks.	1,000	36–41
Magnesite brick, 9-in. straight (f.o.b. wks)	ton	65–68
9-in. arches, wedges and keys.	ton	80–85
Scraps and splits .	ton	85
Silica brick, 9-in. sizes, f.o b. Chicago district .	1,000	48–50
Silica brick, 9-in. sizes, f o.b. Birmingham district .	1,000	48–50
F o.b Mt Union, Pa .	1,000	42–44
Silicon carbide refract. brick, 9-in.	1,000	1,100.00

Ferro-Alloys

Ferrotitanium, 15-18% f o b. Niagara Falls, N Y. .	ton	$200.00 –	$225.00
Ferrochromium, per lb. of Cr, 6-8% C	lb.	.11½	.11¾
4-6% C... .	lb.	.12 –	.13
Ferromanganese, 78-82% Mn, Atlantic seabd. duty paid.. . .	gr. ton	105.00 –	107 50
Spiegeleisen, 19-21% Mn..	gr. ton	35.00 –	37.00
Ferromolybdenum, 50-60% Mo, per lb Mo	lb.	1.90 –	2.15
Ferrosilicon, 10-15%.....	gr. ton	38.00 –	40.00
50%................	gr. ton	80.00 –	85.00
75%................	gr. ton	150.00 –	160.00
Ferrotungsten, 70-80%, per lb. of W........	lb.	$0.90 –	$0.95
Ferro-uranium, 35-50% of U. per lb of U .	lb.	6.00 –	....
Ferrovanadium, 30-40%, per lb. of V .	lb	3.50 –	4.00

Ores and Semi-finished Products

Bauxite, dom. crushed, dried, f.o b. shipping points	ton	$6.50 –	$8.75
Chrome ore, Calif. concentrates, 50% min Cr_2O_3	ton	22 00 –	23.00
C i f Atlantic seaboard	ton	18 50 –	19.00
Coke, fdry , f o b ovens	ton	9 25 –	9.50
Coke, furnace, f o b ovens	ton	8 00 –	8.50
Fluorspar, gravel, f o b mines, New Mexico	ton	17.50 –	....
Fluorspar, No 2 Lump—Ky. & Ill mines .	ton	25.00 –	....
Ilmenite, 52% TiO_2 .	lb	.01½–	.01¾
Manganese ore, 50% Mn, c i f Atlantic seaport	unit	.33 –	....
Manganese ore, chemical (MnO_2)	ton	75.00 –	80.00
Molybdenite, 85% MoS_2, per lb MoS_2, N Y	lb	.65 –	.70
Monazite, per unit of ThO_2, c i f , Atl. seaport	lb.	.06 –	.08
Pyrites, Span , fines, c i f. Atl seaport .	unit	.11½–	.12
Pyrites, Span , furnace size, c i f Atl seaport .	unit	.11½–	.12
Pyrites, dom fines, f o b mines, Ga	unit	.12	
Rutile, 95% TiO_2	lb.	.12 –	....
Tungsten, scheelite, 60% WO_3 and over, per unit WO_3	unit	8.00 –	8.50
Tungsten, wolframite, 60% WO_3 and over, per unit WO_3	unit	7.50 –	8.00
Uranium ore (carnotite) per lb of U_3O_8 .	lb.	3.50 –	3.75
Uranium oxide, 96% per lb. U_3O_8	lb	2.25 –	2 50
Vanadium pentoxide, 99%	lb	12 00 –	14.00
Vanadium ore, per lb V_2O_5 .	lb.	1.00 –	.. ....
Zircon, washed, iron free, f o.b Pablo, Fla	lb	04½–	.13

Non-Ferrous Materials

	Cents per Lb.
Copper, electrolytic .	15 00
Aluminum, 98 to 99%	23.00
Antimony, wholesale, Chinese and Japanese .	7.15-7.50
Nickel, virgin metal . .	25 00 27.00
Nickel, ingot and shot	29 00
Monel metal, shot and blocks	32 00
Monel metal, ingots	38 00
Monel metal, sheet bars	45 00
Tin, 5-ton lots, Straits	40.50
Lead, New York, spot . .	8 00
Lead, E St Louis, spot	8 00 8.125
Zinc, spot, New York .	7 25–7.30
Zinc, spot, E St Louis	6.85–7.05

OTHER METALS

Silver (commercial) .	oz.	$0 64
Cadmium	lb	1 15
Bismuth (500 lb lots). . .	lb.	2.55
Cobalt ..	lb.	3 00@3.25
Magnesium, ingots, 99%....	lb	1.00@1 05
Platinum .	oz	114.00@116 00
Iridium . .	oz.	250 00@275.00
Palladium .	oz	65 00@ 70.00
Mercury	.75 lb.	71 50

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	20.75
Copper bottoms	30.75
Copper rods	20.50
High brass wire	19.50
High brass rods	17.00
Low brass wire	21.10
Low brass rods	22.00
Brazed brass tubing	24.25
Brazed bronze tubing	29.00
Seamless copper tubing	25.25
Seamless high brass tubing..	23.50

OLD METALS—The following are the dealers' purchasing prices in cents per pound:

Copper, heavy and crucible .	11.30@11.50
Copper, heavy and wire	11 25@11.50
Copper, light and bottoms	9 25@ 9.50
Lead, heavy	5.75@ 6.00
Lead, tea	3.50@ 3.75
Brass, heavy	6.25@ 6.40
Brass, light......	5.35@ 5.75
No 1 yellow brass turnings....	6.30@ 6.50
Zinc	3 50@ 4.00

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes..............	$3.29	$3.14
Soft steel bars	3.19	3.04
Soft steel bar shapes..........	3.19	3.04
Soft steel bands...............	3.29	3.19
Plates, ¼ to 1 in. thick..........	3.29	3.14

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

TALLADEGA The Talladega Pipe Co, manufacturer of cast-iron pipe, will make extensions and improvements in its foundry for considerable increase in capacity E O Norman is plant superintendent

CALERA -The O'Neals Lime Works Eureka, Ala, has plans in progress for the construction of a new plant in the vicinity of Calera for the manufacture of hydrated lime, with department for the production of agricultural lime It will consist of 10 kilns and complete operating facilities and labor-saving machinery for an annual production of 1,000,000 bbl The majority of the equipment will be electrically operated The new works is estimated to cost $500,000 The Schaffer Engineering & Equipment Co, 2818 Smallman St, Pittsburgh, Pa, is preparing plans The company has recently removed its general offices from Birmingham to the present plant at Eureka John H Adams is president

ANNISTON The Independent Soil Pipe Co, recently formed with a capital of $75,000, to manufacture cast-iron pipe, has acquired the local plant of the Ajax Foundry Co, and will operate at this location Extensions and improvements are planned in the present works R B Carr is secretary and R T House, general manager

Arkansas

BERRYVILLE H H Beal is organizing a company to construct and operate a local plant for the manufacture of lime products Work will be placed under way at an early date

ARKADELPHIA The Arkadelphia Milling Co is planning for the erection of a number of new buildings at its plant for the production of molasses and affiliated products W N Adams is general manager

Arizona

DOUGLAS The Calumet & Arizona Mining Co., Calumet Mich, has arranged an appropriation of $500,000 for extensions and improvements in its smelting plant at Douglas, including the installation of a new crushing, sampling and ore-treating plant It is expected to commence construction at an early date and complete the installation in the fall

California

EMERYVILLE The Westinghouse Electric & Mfg. Co, East Pittsburgh, Pa, and First National Bank Bldg, San Francisco has awarded a contract to the Ralph McLeran Co, Hearst Bldg, for the erection of the first unit of a new plant at Green and 62nd Sts, Emeryville, to be 1- and 2-story, estimated to cost close to $200,000, with equipment It will be operated by the Westinghouse High Voltage Insulator Co, a subsidiary organized, and used exclusively for porcelain insulator manufacture Four oil-burning kilns will be installed and this battery will ultimately be increased to 12 such kilns California clays will be utilized for the manufacture Ray P Jackson, formerly located at the East Pittsburgh works, will be general manager at the plant

HUNTINGTON BEACH -The Pacific Gasoline Co is planning for the installation of a large gasoline-absorption plant on local site, estimated to cost close to $100,000. Headquarters of the company are at Los Angeles W J Bower is president and general manager E T Hitchcock will be in charge of construction

LOS ANGELES- The American Agar Co, San Diego, operating a local plant for the manufacture of gelatin from seaweed, has been granted permission by the Board of Harbor Commissinooners to construct and operate a similar plant on site selected at Fish Harbor, San Pedro. It is estimated to cost close to $200,000, with machinery. A present experimental plant at Glendale, Calif., will be removed to the new location. Dr. C. F. Farrow is president.

PASADENA—The Art Concrete Works, 364 South Fair Oaks Ave, has plans under way for the erection of a 1-story addition to its cement composition plant, 36x80 ft.

SAN JOSE--The Pacific Gas & Electric Co., 445 Sutter St, San Francisco, will install a new artificial gas-generating plant on local site estimated to cost approximately $100,000

Colorado

DENVER—The Midwest Refining Co, First National Bank Bldg, will commence the immediate erection of a third unit at its gasoline-refining plant in the Salt Creek field, to increase the capacity to about 100,000 gal per day

Connecticut

HARTFORD The Hartford Rubber Works, a subsidiary of the United States Rubber Corp, is planning for the rebuilding of the portion of its plant, destroyed by fire, Feb 3 The bulk of the loss was confined to the machinery

Georgia

CEDARTOWN—The T J Rice Co, LaGrange, Ga, operating a local iron foundry, is planning for the immediate establishment of a new plant at Cedartown It is proposed to continue the present plant at LaGrange

Idaho

GLENNS FERRY - The American Mining & Development Co is perfecting plans for the installation of a new milling plant at its local properties Charles Alban is president

Illinois

CHICAGO The Goldsmith Brothers Smelting & Refining Co, 5841 Throop Ave, has commenced the erection of its proposed new plant additions, to consist of a 1-story structure, 15x135 ft., at Throop Ave and 58th St, to be used for the production of copper sulphate, and a similar 1-story building at Ada and 59th Sts, to be equipped as a smelting plant. The expansion will cost about $200,000, including machinery

GRANITE CITY -The Union Starch & Refining Co is completing plans for the construction of a new 1-story addition, 10x75 ft, to cost about $15,000 J E Irwin is secretary

CHICAGO -The Lake View Brick Co., 2758 Irving Park Blvd, has purchased property at Irving Park Blvd. and California Ave., 666x1320 ft., for a consideration of $45,000, to be used for an addition to its plant.

CHICAGO—The Northwestern Foundry Co., 662 West Roosevelt Rd, has awarded a contract to William F Solomon & Co., 175 West Jackson Blvd, for the rebuilding of a 1-story foundry at its plant, 50x126 ft, recently partly destroyed by fire The company manufactures grey iron castings.

CHICAGO—The Chicago Extruded Metals Co, recently organized, has commenced the construction of a new plant on 54th Ave, near 19th St, Cicero, for the manufacture of brass products It is estimated to cost in excess of $200,000, with machinery

Indiana

WARSAW—The Interstate Public Service Co, Board of Trade Bldg., Indianapolis, has plans in preparation for the installation of a new filtration plant at Center Lake, Warsaw, for the local water system, estimated to cost $75,000.

FORT WAYNE—The Dudlo Mfg. Co., Wall St, manufacturer of electric wire products, is said to be planning for the immediate rebuilding of the portion of its enameling department, destroyed by fire, Jan. 29, with loss approximating $10,000.

SHELBYVILLE—Fire, Jan 30, destroyed the local plant of the Kennedy Car Liner & Bag Co., manufacturer of paper products, with loss estimated at $200,000, including machinery. A temporary plant will be established pending the rebuilding of the works. The company maintains a branch at Greensburg, Ind. Fred W. Kennedy is president.

Kentucky

BOWLING GREEN—The Central Producing & Refining Co. has acquired property in Warren and Allen Counties, and has preliminary plans under consideration for the erection of a new oil-refining plant.

MARION—The Big Four Fluorspar & Ore Co, 903 Farmers' Bank Bldg, Pittsburgh, Pa., is perfecting plans for the erection of a new mining and milling plant on site near Marion, comprising a number of 1-story buildings, estimated to cost close to $100,000, including machinery. W. J Strassburger is president

Louisiana

NAPOLEONVILLE—The local refinery of the Oakley Sugar Co. has been acquired by new interests, headed by Geoffrey Barton and C. C Percy. A company will be organized to operate the plant, and a number of extensions and improvements made

Maryland

BALTIMORE — The Prudential Oil Corp., Fairfield, has filed plans for the erection of an addition to its local oil storage and distributing plant, 40x120 ft, estimated to cost $100,000 Four steel tanks will be installed.

Massachusetts

MALDEN — The Malden & Melrose Gas Light Co will soon commence the erection of an addition to its artificial gas plant to double the present capacity. The retorts will be designed for automatic coal-feeding The expansion is estimated to cost close to $400,000, including equipment.

SPRINGFIELD—The Springfield Gas Light Co. has tentative plans under consideration for the rebuilding of the portion of its artificial gas plant, destroyed by fire, caused by an explosion, Feb 1 with loss estimated in excess of $300,000, including equipment. It is said that new plant will be established in another location

Michigan

MANISTIQUE — The Manistique Brass & Bronze Co, recently established to manufacture a line of brass and bronze products, is arranging for the immediate erection of a new 1-story addition

IRON MOUNTAIN —The Ford Motor Co., Highland Park, is planning for the erection of a large chemical plant in this vicinity, to be used in connection with its iron ore and blast-furnace properties It is estimated to cost in excess of $750,000, with machinery

JACKSON -- Dr D Robinson, 108 South Jackson St, is taking bids through Architect H Graf, Chamber of Commerce Bldg, for the erection of a 2-story and basement chemical laboratory on West Main St, 56x75 ft., estimated to cost $50,000

WHITE PIGEON — The Eddy Paper Co., Three Rivers, Mich, will abandon plans temporarily for the proposed extensions and improvements at its local mills, used for carton production, estimated to cost close to $400,000. The plant will be utilized for other purposes, and a new 1-story building erected.

Minnesota

HIBBING—The Oliver Iron Mining Co., Duluth, is perfecting plans for the construction of a new crushing and screening plant, 89x105 ft., at its Hull Rust mining properties, estimated to cost close to $100,000 F. R Mott is general superintendent

Mississippi

GULFPORT -The Gulf Coast Refining Co. will take bids at once for the installation of additional equipment at its crude oil works, in connection with proposed extensions, estimated to cost about $35,000.

New Hampshire

NEWINGTON—Fire, Jan. 23, destroyed the chemical laboratory at the local plant of the Atlantic Dyestuff Co., Ames Bldg., Boston, Mass., with loss estimated at $25,000. It is planned to rebuild.

New Jersey

ELIZABETH—The Stanwood Rubber Co., Newark Ave., operating a local plant for the manufacture of automobile tires, recently reorganized, will install additional machinery for the manufacture of cord tires. The works have been idle for about a year and were acquired from the receiver. S. P. Woodard has been elected president of the new company and Charles K. Cooper assistant treasurer. C. O. Corey is superintendent.

ELIZABETH—The Standard Oil Co. of New Jersey, 26 Broadway, New York, has plans under way for the erection of an addition to its local Bayway refinery, 125x200 ft., to be used as a paraffin plant. It is estimated to cost close to $500,000, including machinery.

NEWARK—K. Kaufmann & Co., 169 Murray St., manufacturers of leather goods, are taking bids on a general contract for the erection of a 3-story addition, 65x100 ft., to cost about $35,000. William E. Lehman, 738 Broad St., is architect.

NIXON (New Brunswick)—Fire, Jan. 26, destroyed the vaporization department at the plant of the Nixon Nitration Co., which has been used for some time past for the production of celluloid products. An estimate of loss has not been made. It is planned to rebuild.

New York

SYRACUSE—Plans are being perfected for the organization of a new company to be known as the Syra-Cord Rubber Co., to take over and operate the local plant of the Syracuse Rubber Co. The new company will be capitalized at $1,000,000, and purposes to make extensions and improvements in the existing works. Production will be devoted to cord tires and kindred rubber products.

WATER VALLEY—The Water Valley Foundry Co. has tentative plans under consideration for the rebuilding of its foundry, destroyed by fire, Jan. 25.

North Carolina

STATESVILLE—The C. H. Turner Foundry Co., Inc., recently organized with a capital of $100,000, will commence the immediate erection of a new 1-story foundry, 75x135 ft., for the manufacture of iron castings. It will be equipped for an initial daily production of about 6 tons. C. H. Turner is president, and D. C. Ritchie, secretary and treasurer.

Ohio

ZANESVILLE—The Columbia Chemical Division of the Pittsburgh Plate Glass Co., Frick Bldg., Pittsburgh, Pa., is taking bids on a general contract for the erection of its proposed new plant at White Cottage, near Zanesville, estimated to cost about $1,500,000, including machinery. A total of eleven 1- and 2-story buildings will be constructed. F. A. Jones, Monumental Bldg., Zanesville, is engineer and local manager.

AKRON—Plans are being completed for the construction of a municipal plant for the production of alum for use at the city waterworks, estimated to cost about $15,000. W. F. Peters, city service director, is in charge.

Pennsylvania

WHITE HAVEN—The Peerless Powder Co. has construction under way on new plant buildings and plans to have the structures ready for the equipment at an early date.

GLENSIDE—The Gulf Refining Co., Frick Annex, Pittsburgh, has plans nearing completion for the erection of a 2-story oil storage and distributing plant at Glenside, estimated to cost $50,000.

CREIGHTON—The Pittsburgh Plate Glass Co., Frick Bldg., Pittsburgh, has acquired the foundry and shops of Yost Brothers, on site adjoining its Creighton works, known as the No. 1 Plant, to be used for proposed extensions.

Tennessee

CHATTANOOGA—The Tennessee Furniture Corp. is planning for the erection of a new building for enameling and porcelain work, in connection with other plant additions to cost about $165,000.

Texas

TEXAS CITY—The Texas Sugar Refining Co. has plans in progress for the erection of a new local refinery, estimated to cost in excess of $100,000, including machinery. It is purposed to have the mill ready for service early in the fall.

PORT ARTHUR—The Gulf Refining Co. has commenced the construction of a new oil plant on local site, to comprise a catalytic distillation unit of 32 stills and auxiliary equipment, re-run plant and other structures, estimated to cost in excess of $250,000, complete.

YOAKUM—The Texas Hide & Leather Co. has work in progress on extensions and improvements in its tannery for extensive increase in production. Plans are also being perfected for the erection of an addition to the sole leather department, for which a list of equipment to be installed will soon be arranged.

Virginia

ROANOKE—The Roanoke Tire & Rubber Co. is perfecting plans for the erection of a new 3-story plant for the manufacture of cord tires for automobile service and other rubber products. Charles H. Kieffer is assistant secretary and general manager.

Washington

OLYMPIA—The West Coast Pulp & Paper Co., recently organized as a subsidiary of the Hawley Pulp & Paper Co., Oregon City, Ore., is perfecting plans and will soon commence the erection of a new local mill, to consist of a paper manufacturing plant, sulphide mill and auxiliary structures, estimated to cost in excess of $500,000, with machinery.

West Virginia

CLARKSBURG—The Liberty Glass Co., manufacturer of window glass, is planning for extensions in its plant, including the remodeling of the present plant from hand to machine operated. Considerable additional machinery will be installed. Hugh Smith, an official of the company, is in charge of purchases.

Industrial Developments

PAPER—The Grass Fiber Pulp & Paper Corp., Leesburg, Fla., has commenced operations at its new pulp mill, recently completed, and expects to begin the production of paper in the other plant departments at an early date. The plant will be devoted to the manufacture of paper from saw grass.

Paper mills in the Michigan district are advancing production and adding to their working forces.

The American Writing Paper Co., Holyoke, Mass., is maintaining regular operations at its different mills in this section, giving employment to normal working forces.

GLASS—The Baker Brothers Glass Co., Okmulgee, Okla., manufacturer of window glass, has resumed operations at its plant at Sapulpa, Okla., and will develop capacity production. The Okmulgee works has been closed and the skilled employees have moved to the Sapulpa plant. Repairs and improvements will be made to the machinery at the idle plant during the coming weeks, and it is planned to reopen late in the spring. It is expected to resume production at the Augusta, Kan., factory at an early date, following a shut-down for some time past.

The Millville Bottle Works, Millville, N. J., has resumed service at one of its large glass tanks, recently closed down through failure of the furnace. Production will be advanced at the plant.

Glass plants in western Pennsylvania are running full, giving employment to regular working forces. Night shifts have been scheduled at a number of the factories.

LEATHER—The American Hide & Leather Co., New York, N. Y., has advanced production at its different tanneries, and is now running at close to normal. It is said that heavy incoming orders insure full capacity for some time to come.

Glazed kid plants at Camden, N. J., and Wilmington, Del., are operating at a pre-war basis, giving employment to regular working forces. It is expected that increasing orders now being received will advance production to maximum at an early date at the majority of the tanneries.

Burk Brothers, 923 North 3rd St., Philadelphia, Pa., manufacturers of glazed kid, are operating their tannery at about 75 per cent of normal. An early increase is expected.

V. & F. W. Filoon Co., Brockton, Mass., manufacturer of sole leather, is running full in all departments. Maximum output is being developed in the welting division.

Gensemer & Salem, operating two tanneries at Pine Grove, Pa., are maintaining full production at both plants, giving employment to regular working forces. No contract tanning is being handled at the present time.

CERAMIC—The Burton-Townsend Co., Zanesville, O., manufacturer of brick, is planning for an early increase in production and has extensions and improvements in progress for this purpose. The advance will average from 25 to 30 per cent. R. C. Burton, one of the heads of the company, is also planning for the construction of a new plant in this vicinity.

Potteries in East Liverpool, O., report increasing business and the majority of the general ware plants are now running on a full basis, with full working forces.

Brick-manufacturing plants in Georgia are operating at full capacity and expect to maintain this schedule for an indefinite period.

The Niloak Pottery Co., Benton, Ark., manufacturer of art and novelty ware, is maintaining full operations at its plant and plans for the early erection of a number of new kilns for increased manufacture. The working force will be enlarged.

Brick plants at Philadelphia, Pa., equipped with mechanical drying systems, are maintaining capacity production, with full working forces. About 25 per cent of the local plants, arranged for seasonal operation only, are closed down.

The Best Brick Co., Evansville, Ind., is running at full capacity and will maintain this schedule for an indefinite period. The company recently received an order for 500,000 face brick for the new works of the Ford Motor Co., at Chicago, Ill.

IRON AND STEEL—The Bethlehem Steel Corp. is arranging for the early blowing in of another blast furnace at its Steelton, Pa., works. Repairs are in progress at furnace E at the mills, and it is expected to have this unit ready for service at an early date. Other departments of the works will also advance operations at an early date.

The Thropp blast furnace at Earlston, near Bedford, Pa., has completed relining and other repairs, and plans are under way to blow in at an early date. The company's coke ovens in the Broad Top section will also be placed on the active list at the same time.

The Sloss-Sheffield Steel Co., Birmingham, Ala., will continue the employment of convict labor at its mills as a result of a bill signed by Governor Brandon, deferring any change in the present convict leasing system until March, 1927. The plant is continuing production at full capacity.

The Harrow Spring Co., Kalamazoo, Mich., is maintaining production at its two rolling mills and electric furnace, giving employment to a regular working force. The local plant will be included in the recent merger of the Steel & Tube Co. of America, Chicago, Ill., and the Youngstown Sheet & Tube Co., Youngstown, O.

The Reading Iron Co., Reading, Pa., has placed its universal mill on 9th St. in operation, after a shut-down since last November. The mill will give employment to about 100 men on single turn.

In the Sharon, Pa., district, the Carnegie Steel Co. has all departments of its mills running full with the exception of the by-product coke ovens, which have been idle for about 24 months. The American Sheet & Tin Plate Co. is operating at full capacity at its hot mills, while the American Steel & Wire Co. has a schedule of approximately 75 per cent of capacity. The Sharon Steel Hoop Co. is in active service at all of its local finishing mills, with the Youngstown, O., plant running at normal capacity. Six of 14 blast furnaces are on the active list, 3 of these being those of the Carnegie Company, 2 the Shenango Furnace Co. and 1 of the Reliance Coke & Furnace Co., at Sharpsville.

The Witherbee, Sherman Co., New York, has postponed the blowing in of its blast furnace at Port Henry, N. Y., scheduled for Feb. 1, owing to coke shortage. It is expected to apply the torch before the close of the month if coke now in transit is received at the plant. The plant has been idle for about 12 months, during which time a number of improvements and extensions have been made. The furnace operates on magnetic ore and has a rated production of 250 tons of pig iron per day. A new blast furnace is now in course of construction at the plant, to have an output of 500 tons per day; this unit is scheduled for blowing in during April.

The Carnegie Steel Co. has active construction under way on an addition to its byproduct plant at Clairton, Pa. The present plant, said to be the largest of its kind in the world, consists of 640 ovens, arranged in 10 batteries of 64 each. The extension will provide for 366 new byproduct coke ovens, a benzol motor fuel recovery plant and a byproducts plant.

MISCELLANEOUS—The Kansas City Malleable Castings Co., Kansas City, Mo., has resumed production at its plant after a shut-down of more than 18 months. The Dayton Malleable Iron Co., Dayton, O., is interested in the company.

Graphite mines in the vicinity of Burnet, Tex., are now producing at the rate of about 16,000 tons of ore per day.

Rubber mills at Akron, O., are operating on a basis of 85 per cent of capacity, including tires and other rubber products.

New Companies

THE CHLORIDE PRODUCTS, INC., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $1,000,000, to manufacture sodium, potash, magnesium and affiliated products.

THE STERLITE FOUNDRY & MFG CO, Auburn, Ind., has been incorporated with a capital of $75,000, to manufacture special metals, metal castings, etc. The incorporators are J. A. Rendel, R. J Schweitzer and A. L. Kuhlman, all of Auburn

THE FRANK SHINN CO., INC, Philadelphia, Pa, is being organized under state laws to manufacture paints, varnishes colors, etc Application for a state charter will be made on Feb. 19. The company is represented by John E. Gensemer, Crozer Bldg., Philadelphia.

THE SANDY RIVER OIL CO., Ashland, Ky., has been incorporated with a capital of $100,000, to manufacture petroleum products The incorporators are Harry L Claiborne and R D. Davis, Ashland The last noted represents the company.

VINCENT & CO, INC, 400 North Michigan Ave., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture cleaning fluids, compounds, etc The incorporators are John A. Vincent, Chauncey Blair and Leonard M Prince

THE STANDARD SMELTING & REFINING CO 819 Jersey Ave, Jersey City, N J, has filed notice of organization to operate a metal smelting and refining works. Harry M Cohan, 24 East 42nd St., Bayonne, N J, heads the company

THE STARK GLASS CO, Massillon O, has been incorporated with a capital of $30,000, to manufacture glass products The incorporators are John A. Vincent, Chauncey ford, both of Massillon.

CHARLES S WOOD & CO., East Orange, N. J., care of the New Jersey Registration & Trust Co, 525 Main St, East Orange, representative, has been incorporated with a capital of $125,000 to manufacture asbestos products The incorporators are Charles O. Geyer and associates.

THE NEWMAN-KOHN PAPER CO, Newark, N. J, has been incorporated with a capital of $100,000, to manufacture paper products The incorporators are Albert Newman, Leon A. and Sylvan H. Cohn, 790 Broad St, Newark The last noted represents the company

THE BETWK CORP, New York, N. Y, care of I L Dreeben, 50 Broad St., New York, representative, has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts, dyestuffs, etc The incorporators are J B Bateman and S D Cowl.

THE BEAR STATE OIL CO., Jefferson City, Mo., has been incorporated under state laws to manufacture petroleum products. The incorporators are R H. Muzzy, H C Welble and G. W. Foland, all of Jefferson City.

THE MELLINGER TIRE & RUBBER CO, care of the Corporation Trust Co. of America, du Pont Bldg, Wilmington, Del, representative, has been incorporated under Delaware laws with capital of $600,000, to manufacture tires and other rubber goods.

THE HOLMESBURG CONCRETE CO., Philadelphia, Pa., has been incorporated with a capital of $30,000, to manufacture cement and concrete products. B. F. Zimmerman, 7660 Frankford Ave, is treasurer and representative.

THE CUMBERLAND CARBON CO, Charleston, W. Va, has been incorporated under state laws to manufacture carbon products The incorporators are Roswell T Hapwood, George E Thomas and Oscar Nelson, all of Charleston.

THE FRAZIER DRAIN TILE CO, Bluffton, Ind, has been incorporated with a capital of $75,000, to manufacture clay tile, blocks and kindred products The incorporators are Luther M Frazier and W Hobart Frazier, both of Bluffton

THE NEWBURGH LIME MFG CO, Newburgh, N. Y, care of J V McKee, 51 Chambers St, New York N. Y, representative, has been incorporated with a capital of $20,000, to manufacture lime products The incorporators are W C Martin, M Gorchoff and A Lecheman, Newburgh

THE MOUNT VERNON LEATHER CO, INC, Philadelphia, Pa, has been incorporated with a capital of $36,000, to manufacture leather products Harvey Freeman, 2131 North 19th St, Philadelphia is treasurer and representative.

THE ASBURY STEEL PRODUCTS CO., Indianapolis, Ind., has been incorporated with a capital of $100,000, to manufacture steel specialties. The incorporators are Jerry A. Gallivan, Edward E. Asbury and Everett A. Marcy, all of Indianapolis.

THE MASTER GASOLINE CORP, Oklahoma City, Okla., has been incorporated with a capital of $250,000, to operate a gasoline extraction plant, manufacture refined oils, etc. The incorporators are Benjamin H. Mason, C. B Kendrick and J. E Crowder, all of Oklahoma City.

H LOOS & CO., 409 Ogden St, Jersey City, N. J., have filed notice of organization to manufacture grindstones and other abrasive products. Herman Loos heads the company.

THE GENESEE FELDSPAR CO Rochester, N Y, care of William Armstrong, Powers Bldg, Rochester, representative has been incorporated with a capital of $100 000, to operate a feldspar mill for commercial production The incorporators are S R Parry, W C. Fredericks and G E Worth, Rochester

THE GLEASONITE PRODUCTS CO, Boston, Mass, care of Edmund S. Hellings, Equitable Bldg., Wilmington, Del, representative, has been incorporated under Delaware laws with capital of $1,000,000, to manufacture synthetic rubber products, etc The incorporators are Charles Peters, Louis and Max Brown, Boston

THE MASON CITY BRICK & TILE CO., Mason City, Iowa, care of the Corporation Trust Co of America, du Pont Building, Wilmington, Del, representative, has been incorporated under Delaware laws with capital of $3,000,000, to manufacture brick, tile and kindred burned clay products

THE FANDANGO MILLS, INC Millburn, N J, has been incorporated with a capital of $125,000, to manufacture paper and binder board products The incorporators are M C Durr, Frank C Trubee and George J Berstler, Millburn The last noted represents the company

THE PHYMOS CHEMICAL LABORATORIES, INC, Pensacola, Fla, has been incorporated with a capital of $15,000 to manufacture chemicals and chemical byproducts W J MacIntire is president, and W A Pourties, secretary and treasurer, both of Pensacola.

THE LEIGHTON CHEMICAL CO, Colchester (Delaware County), N. Y, care of A. G. Patterson, Walton, N Y representative, has been incorporated with a capital of $150,000, to manufacture wood alcohol and kindred products. The incorporators are F Leighton, E L White and E. N Cary.

THE COMMONWEALTH MICA CO, care of the Colonial Charter Co, Ford Building, Wilmington, Del, representative has been incorporated under Delaware laws, with capital of $1,000,000, to manufacture mica products

Capital Increases, etc.

THE MERRIAM PAPER CO, Phoenicia, N Y., has filed notice of increase in capital from $20,000 to $101,000.

THE CONNECTICUT OIL CO, Waterbury, Conn, has arranged for an increase in capital from $150,000 to $250,000 for expansion

THE FRAZER PAINT CO, 2475 Hubbard St, Detroit, Mich, has filed notice of increase in capital from $100,000 to $250,000

THE PATTERSON GLASS MFG CO, Cameron, W Va, has arranged for an increase in capital from $50,000 to $150,000 for proposed expansion.

THE NEW YORK COLOR & CHEMICAL CO., 12 Gold St., New York, with plant at Belleville, N J, has filed notice of increase in capital from $100,000 to $350,000.

THE SIEMON HARD RUBBER CORP., Bridgeport, Conn, has filed notice of change of name to the SIEMON CO.

THE TRANSYLVANIA TANNING CO, Brevard, N C, has arranged for an increase in capital from $25,000 to $1,000,000 for proposed expansion.

THE NATIONAL HELFRICH POTTERIES CO, Evansville, Ind., has increased its capital from $200,000 to $250,000

THE PETERS PETROLEUM CORP, Tulsa, Okla, is disposing of a preferred stock issue of $2,500,000 a portion of the proceeds to be used for expansion Charles B. Peters is president

THE WEST HAVEN RUBBER CO West Haven, Conn, which recently took over the local plant of Kelley Tire & Rubber Co, is perfecting plans for reorganization, with increased capitalization.

THE UNITED STATES GLASS CO., South 9th and Bingham Sts., Pittsburgh, Pa., is arranging for the sale of a stock issue of $1,000,000, the proceeds to be used for general operations, expansion, etc. Ernst Nickel is secretary.

THE CLINCHFIELD PORTLAND CEMENT CO., Richmond, Va., has arranged for an increase in capital from $2,000,000 to $3,000,000 for general expansion.

THE AMERICAN CORRUGATED PAPER PRODUCTS CORP., 221 West 26th St., New York, N. Y., has filed notice of increase in capital from $300,000 to $500,000 for expansion.

THE INLAND WHITE LEAD CO., 741 Boston Ave., Chicago, Ill., manufacturer of paints, etc., has filed notice of increase in capital from $40,000 to $150,000.

THE SHAFFER OIL & REFINING CO., 208 South La Salle St, Chicago, Ill., is disposing of a note issue of $594,000, a portion of the proceeds to be used for extensions.

THE MIDLAND PAPER CO., 322 West Washington St, Chicago, Ill., has filed notice of increase in capital from $100,000 to $200,000.

THE NEW NIQUERO SUGAR CO., 129 Front St., New York, N. Y, operating sugar refineries, has filed notice of increase in capital from $1,500 000 to $5,000,000 for expansion.

THE GOODALE CO., Kalamazoo, Mich., has arranged for a change of name to the D. R C Foundry Co

THE HUMPHREYS OIL CO., Mexia, Tex., operating oil refineries, has filed notice of increase in capital to $15,000,000 for general expansion

THE F E REED GLASS CO, 860 Maple St., Rochester, N Y., manufacturer of hollowware products, has arranged for an increase in capital from $200,000 to $750,000 for expansion.

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va, May 7 to 9

AMERICAN CERAMIC SOCIETY is holding its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O., April 28 to May 4.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 10 and 11 at the House of the Institution of Civil Engineers, London, S W. 1.

NATIONAL FOREIGN TRADE COUNCIL has postponed its annual conference from April 25, 26 and 27, to May 2, 3 and 4. It will be held in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St, New York City: March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 New York, February 21, 1923 Number 8

The Chauffeur Aspires

A GOOD reputation achieved through laborious effort and sheer merit has always been the envy of the near-worthy and the goal of the covetous. Those who are on the fringe of importance or greatness or distinction or respectability like to persuade themselves that they are, in point of fact, quite within the fold. And so it happens that periodical assaults are made on the citadel of engineering by various crafts and trades, conscious of the good name and reputation of the engineer and seeking as a trophy the use of the word "engineer" in describing their vocations. The plumber would be a sanitary engineer, the fireman a fuel engineer, the tailor a sartorial engineer, the barber a tonsorial engineer, and so on with the butcher, the baker and candlestick maker.

And now comes the chauffeur. A recent item in New York papers records the organization of chauffeurs into the Society of Professional Automotive Engineers. There is a slight distinction in the name from that of the well-recognized Society of Automotive Engineers, which is one of the great national engineering bodies. But undoubtedly the distinction, though slight, is significant in the minds of the chauffeurs. They, be it known, are *professional* automotive engineers while the others, forsooth, are doubtless only amateurs. Our new aspirants for engineering recognition probably look upon themselves as very *practical* men, while such theorists as produced the Liberty motor or who now design modern automotive mechanism are mere academicians. But there is a further distinction. We learn from the news item that "There is a great difference between an automobile driver and an automotive engineer." So there is; but not the one the reader has in mind. We learn further from the president that: "Our organization is composed of professional operators of automobiles in private employment. It aims to place the profession on a higher plane and to protect its members from increasing laws levied on operation of automobiles." We quote from the interview without editing. And we learn that taxicab drivers are not eligible for membership, while the lowly commercial truck driver is not even mentioned. Evidently the "great difference between an automobile driver and an automotive engineer" is principally one of vehicle. One has to sit at the steering wheel of a limousine in order to be eligible to the Society of Professional Automotive Engineers.

For the moment we can think of no title or designation that has suffered more from illegitimate use at the hands of aspiring craftsmen, unless it be that of "professor." Who used to make the balloon ascension and parachute drop at the county fair in the old days? None other than our old college friend Professor Blimp. And who now presides over the local parlor for manicuring and chiropody? Professor Foote, of course. Who teaches dancing, if not Professor Tango? And is not the favorite headliner on the vaudeville bill frequently Professor Aladdin with his black art? Finally there has been no more chronic aspirant than Professor Bump, the phrenologist. Small wonder that this title has almost fallen into disuse among those who earn and deserve it.

Reputation has been the theme of some of the finest gems of literature. We immediately recall the plaint of *Iago* in "Othello." when he says, "Who steals my purse steal trash . . . but he that filches from me my good name robs me of that which not enriches him and makes me poor indeed." Again he says that it is "Oft got without merit and lost without deserving." And in "Richard II" *Mowbray* says that without spotless reputation "men are but gilded loam or painted clay." We presume that the chauffeur will not be the last to filch the name and reputation of the engineer with which to gild the loam or paint the clay of his humble but useful calling. Nor have we any formula for preventing encroachment on the proper use of the title. We protest against it, but evidently it is something which, like the poor, we have always with us.

Another Problem For the Fertilizer Industry

IN OUR issue for Jan. 10 we published an editorial entitled "Long-Term Credits in the Fertilizer Industry." Some of the discussion which that editorial called forth has already appeared in Readers' Views and Comments, but we believe there are several points that are worth further emphasis. Perhaps the most significant has to do with the marketing of fertilizer. Certain localities seem to have become a kind of dumping ground for fertilizer. Perhaps they do not consume enough material to be classed as a field of major sales activity, but apparently they are the happy hunting ground for the disposal of surplus stocks of various kinds. "Sell at cost or even below, but sell anyway!" That is evidently the slogan.

What results is a veritable orgy of competition. A contract is signed with one salesman. Another calls who offers a better price. The customer then calls up the first company and demands a lower price or cancellation of the contract. Or, worse than that, he does not even notify the first company but buys from salesman No. 2. In a buyer's market the seller can do nothing but grin and bear it. If he sues he will lose a customer. So the net result is that contracts amount to nothing. The same is true of the price list.

Several solutions have been suggested. One is to

make consumption and production balance in the industry, either by controlling production or by increasing consumption. Of course the former is impossible except by a now illegal combination of producers, and the latter is a much-desired and sought-for end. It might, however, prove somewhat of a boomerang, for increasing demand would probably lure others into the field of production. The more practical solution is that of insisting through the National Fertilizer Association that contracts and sales agreements be strictly enforceable. It is distinctly within the power and province of the association to work for good business practices. It would be a principle easy to enforce through such an organization. No one is the gainer from present conditions except possibly the consumer and at the sacrifice of one of the cornerstones of business.

What's in The Ruhr?

SIX weeks ago Germany's largest and most tangible asset was the great industrial district lying in the valley of the Ruhr. Before its occupation by the French and Belgian troops, it was a principal source of coal, the seat of a tremendous iron and steel industry, the heart of Germany's industrial system. Today, production in that district is practically at a standstill. No man can predict the ultimate result of the French occupation nor its effect on the world's economic structure.

In the belief that more information about the economic and industrial aspect of this situation would be welcomed by our readers, an editorial survey has been made of available economic data bearing on the Ruhr district. In another place in this issue there will be found an attempt to answer, from a chemical and industrial viewpoint, the important question, "What's in the Ruhr?"

Notwithstanding present uncertainties in the situation, there have been a number of developments and apparent tendencies that are gradually helping to crystallize sentiment in this country and to aid in our appraisement of what the situation portends. For one thing, it is becoming increasingly apparent that the policy and plan which has guided the French is not one that will be consummated by the developments of a week or month. It is the building of a permanent structure, organizing for the long swing rather than for the immediate profit. This attitude is beginning to be shown in a number of ways, such as the strategic control of traffic with the idea of exacting taxes and tariffs. The only definite attempts so far to demand reparations in kind have been in the case of coal—which is, of course, merely the justifiable collection of a debt long overdue. The attitude toward the chemical plants has been less discernible, but underlying it is this same long-swing policy. Incidental interferences such as the confiscation of specific shipments of raw materials have been reported, it is true, but this can scarcely be regarded as the permanent plan. The coal-tar crudes and intermediates needed by the German dye industry will not find a ready market elsewhere, and for taxable purposes it would seem more logical that they be allowed to pass into consumption and taxes enacted on the finished goods—i.e., the dyes and reparation products already demanded by France and Italy.

But the most important tendency to become evident —the real riddle of the Ruhr—is the great political problem in bringing together in a workable unit the German interests of the Ruhr and the French interests of Lorraine. As long as the one controls the coal and the other the iron ore, they stand at loggerheads. To revert to pre-war conditions, with one country in command of both resources, would seem to be the first requisite for production. But it is evident, too, that insurmountable difficulties will crop up constantly in any co-operative arrangement in which France is the employer and Germany the worker. Therefore, it is obvious that peaceful economic settlement can come only with a solution of the political difficulties. To hazard a guess as to the effectiveness of the proposals of the separationists is perhaps immature, but it would seem that at times the coming of such an event is already clearly foreshadowed.

How is this trouble in the Ruhr going to affect us? Temporarily, at least, we are more likely to be benefited than harmed. Our export trade in foodstuffs and raw materials will probably suffer because of the district's loss of purchasing power, but this will undoubtedly be more than compensated by the gain in our exports of manufactured goods, of iron and steel products, and of similar commodities originally supplied by the industries of the Ruhr.

Our own organic chemical industries, as Dr. HERTY has pointed out with characteristic forcefulness, have fortunately insured us against a recurrence of the tragedy of 1916. We are prepared to supply the American consumer, or the world if necessary, with practically every dye and coal-tar chemical required for uninterrupted production. For the economic good of the world, it is to be hoped that the industrial prostration of Germany can be averted, but it is comforting to know that we are prepared for such an emergency if it does come.

Winged Errors in Chemical Literature

WHEN we chemists get hold of an error it often takes more than a mental crowbar to pry it loose from us. Start a wrong constant in a textbook and there it is, not only in that book but in nearly every one that comes afterward. Of such a defective record a chemist told us the other day that he had looked it up in three different textbooks, and since they all agreed he thought they must be right. But they were all wrong.

A few days ago in discussion with Professor KENDALL of Columbia, who is reviewing the textbooks of the late ALEXANDER SMITH, he referred to the melting point of ammonium sulphate as one of those winged errors that fly through the literature. It seems there was a Frenchman who had worked with ammonium sulphate and developed the facts back in the eighteen-forties or thereabout, and he published his findings, which were correct, in his book. Next somebody else wrote a textbook which became more popular and he was a bit hasty about getting the data on ammonium sulphate, or he may not have read French very well. At all events he put down the melting point as 140 deg. C. and there it started. Everybody else copied it, and now it is standard in the literature.

In point of fact, if ammonium sulphate is heated in a closed tube it does not melt until above 600 deg. C., whereas if heated in an open tube ammonia is given off, the acid salt is formed and it is the acid salt and not ammonium sulphate that melts at 140 deg. C.

The Psychology of Glass As Plant Equipment

THOSE who read Mr. MARSHALL'S interesting contribution on industrial glass in our issue for Jan. 31 must have been struck with the note of practical psychology that he sounded with respect to the use of this material in chemical plant construction. The very quality of glass—fragility—which might be expected to defeat its use as a material of construction has proved, in the case of Pyrex, to be the best insurance against breakage.

We have all grown up in the knowledge that glass is breakable, and this fact is connected in our minds with its quality of transparency. Of two pieces of apparatus, one of transparent glass and the other of opaque earthenware, there would be no question in the mind of a workman as to which he must handle with care and respect for its fragility. Earthenware looks tough and no amount of experience with breakage in clay products would give him the same instinctive respect for it that he would have for transparent, fragile glass. Consequently, although breakage might be expected to be high in plant apparatus made of glass, the reverse is found to be true, because a workman anticipates the likelihood of breakage and handles the transparent material more carefully.

While we can scarcely advocate the extension of this interesting example of psychology to the point of advising that plant apparatus be made fragile instead of rugged in appearance, we think that it does furnish one of the best evidences that glass has by no means reached its full utility as a material of plant construction. Its transparency is one of its greatest merits, and apparently its fragility is by no means the drawback that might have been expected.

An Opportunity For the Tanning Chemist

THERE is a good deal of talk going on about the destruction of wild animals for the fur industry. Until 10 or 12 years ago the wild birds were being killed to such an extent for feathers to decorate women's hats that Congress took measures to stop it, and these were successful. Now we have no brief to present on behalf of moles, squirrels, skunks or muskrats, which are threatened with extermination; we never cared for minks or weasels or foxes around the chicken yard—in fact, we have not yet added the salvation of fur-bearing animals to the reforms we support.

We are, however, always ready to join in any reasonable effort to eliminate rats. They threaten us with disease, they carry the bubonic plague and they are a nuisance to the whole world. Once, years ago, we ventured to suggest editorially that rat skins be tanned and brought into use, but this instigated such an amazing correspondence that it nearly got us into trouble. Nevertheless, we venture again to attack the subject from a somewhat different angle and to call in the aid of chemistry.

In regard to clothes, men wear what their tailors and their wives tell them to wear, so long as their raiment shall be without any distinguishing mark of individuality. Women think more about their clothes than men do, they aspire above all things to be in style and every woman wants her clothes to be "individual" in cut, in trimming and in fabric. But if anybody had told us when we were boys that women would be straining every nerve to possess and wear the skins of skunks, we should not have believed him, although today these very skins are a luxury.

Now rat skins make good leather. The pieces, of course, are small. What is called for is an advance in the art of tanning and in the discovery of a method of joining the edges of the separate pieces by some colloidal turn. Granted that such a material may be produced that is pleasant to wear and durable, we may expect it to become fashionable. Any amount of expense may be added to it by trimming, but even when worn plain, the wearer will achieve merit by encompassing himself or herself in a garment made of it.

Soft leather coats, vests and overcoats are very desirable for men in cold weather, and if they are in fashion women may be trusted to wear them, even in the hottest summer days if the Paris dressmakers should decree it. The main thing is to produce the material, and only a chemist familiar with the technology of leather can do this. The development of such an industry would make the destruction of rats a profitable enterprise—and that would be the end of one of the worst pests of our day and generation.

A Discriminating Benefaction to Science

CHEMISTRY in the West, professional and industrial, will be heartened by the news of a princely gift of over $4,000,000, by ARTHUR H. FLEMING, of Pasadena, to the California Institute of Technology—an act that marks a significant advance in the scientific life of the Los Angeles district in particular and of the Coast region in general. Such a gift is an indication and an appreciation of the vigorous growth and promising vitality of those Western industries whose prosperity depends in large measure on the provision of a sound scientific foundation and the unremitting application of technical research.

Benefactions often fail in their purpose because of a lack of discrimination and foresight on the part of the donor. It is refreshing, therefore, to note that Mr. FLEMING accompanies his gift with suggestions that should receive the careful consideration of all who are concerned with higher education. He earnestly advises that the California Institute limit its enrollment to 2,000 students; this we may interpret as an indorsement of the contention that mere bigness too often connotes emptiness. He recommends that the Institute "specialize in chemistry and physics, under the direction of the most competent men available, with the most liberal provision in the way of salaries and equipment, for the prosecution of such work; that it seek and invite the superior student; that it help and encourage those who are disposed to research, but that the utmost care be exercised in the manner of giving such help and encouragement, keeping always in mind that ill-advised or too free-handed assistance begets weakness rather than strength, and that a man should be helped to help himself."

With such a code of common-sense ideals, and with the financial support of public-spirited citizens such as Mr. FLEMING, the board of trustees of the Institute needs no more than competent scientific direction and the co-operation of the earnest student to insure for California an eminence in technology commensurate with the needs of her rapidly expanding industries.

Readers' Views and Comments

Dühring's Law Of Vapor Pressures

To the Editor of Chemical & Metallurgical Engineering

SIR:—There appeared in the Jan. 24 issue of your journal an article entitled "Theoretical Derivation of the Vapor Curve of Xylol." In this article there is presented what is termed a "novel" method of calculating the vapor pressure. I wish to call your attention to the fact that this method was probably first proposed in 1878 by Dühring, and his since appeared in most of the textbooks on physical chemistry, either under the name of Dühring's relation or as a special case of the more general Ramsay-Young vapor pressure relation. Furthermore, this same method of calculating vapor pressure has appeared recently in *Chemical & Metallurgical Engineering* in the articles by W. L. Badger on the properties of salt solutions. A recent article in the *Journal of Industrial and Engineering Chemistry* (vol. 14, No. 6, page 569, 1922) also called attention to this relation for the calculation of the vapor pressure of certain hydrocarbons derived from coal tar. In view of these facts I cannot but take exception to the statement that this is a novel method for the calculation of vapor pressure.

Newtonville, Mass. BARNETT F. DODGE.

Problems in Sodium Sulphide Manufacture

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your article of Jan. 10, together with the interesting letter of Mr. Hart on "Problems in Sodium Sulphide Manufacture," has mentioned in a way the manufacture from salt cake and from barium chemicals. However, the process which I have developed here I hope will be sufficiently interesting to warrant a note.

We are using niter cake which we charge directly into the sodium sulphide reverberatory type furnace along with 20 to 30 per cent gas-house carbon. The reverberatories are oil fired. The reduction is carried on until approximately 70 per cent of the available Na_2SO_4 content is reduced to Na_2S and is then tapped from the furnace. This charge, after cooling, is ground and dissolved, giving a solution containing sodium sulphide, considerable proportion of Na_2CO_3, Na_2SO_4, $Na_2S_2O_3$, etc. This solution is filtered and barium sulphide added to complete precipitation. The precipitate settles rapidly, the supernatant liquid being decanted directly to the storage tank for the sodium sulphide evaporator. The precipitate, after settling, is filtered over an Oliver filter, then goes to wash tanks. After several washes removing the small amount of sodium sulphide remaining, sulphuric acid is added until all of the precipitate is converted to $BaSO_4$, or blanc fixe, and is sold as a standard article.

The chief features in this process are that what is not converted in the furnace to sulphide is later on converted by the addition of barium sulphide, giving a very pure sodium sulphide solution for evaporation and a high-grade blanc fixe as a byproduct. Moreover, by operating at a lower temperature and not endeavoring to secure such a high-grade sulphide in the furnace, the life of the furnace is more than doubled. The furnaces used have a hearth area of about 160 sq.ft. and produce about 6 tons per day of concentrated sulphide, 70 per cent of which is from the direct furnace reduction, the other 30 per cent from the barium sulphide precipitation.

Metal and Chemicals Extraction Co., Oakland, Calif. B. T. ROCCA.

Rapid Sorting Of Alloy Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—Having had occasion recently to sort a badly mixed stock of bar steel, I attempted to use the method described by M. Galibourg in your issue of Nov. 15, 1922, p. 992. This consisted in measuring the thermal emf. against pure iron wire, when the ends were immersed in a pot of warm mercury.

Our tests did not indicate that it is possible to use this method on a commercial scale. There is undoubtedly a difference in the emf. force for different analyses, but this is in fact so slight that we could not rely upon it. The results we obtained follow:

Steel	Temperature Deg F	Millivolts
Utica oil hardening steel	250	0.6
Swedish iron	248	0 2
Halcomb toolsteel	248	0.9
Ketos oil hardening steel	252	0 5
Clarite high-speed steel	252	0 25
S A E 5120 steel .	252	0 1
Machine steel	250	0 1

The suggestion in the article of using Brinell test was not carried out, but this will not make any material difference. The Brinell hardness of for instance the last two steels will at least under certain circumstances be similar and as the emf. is the same, it would not be possible to separate these two steels by this method. We realize of course that in other special cases it might be possible to use this method to advantage.

E. W. EHN,
Canton, Ohio Metallurgist, Timken Roller Bearing Co.

Long-Distance Hauling of Sulphuric Acid No Longer Feasible

As the transportation of sulphuric acid for long distances is difficult and expensive, the producing plants are located close to the points of consumption. Prior to the war a 200-mile haul for a regular contract delivery of acid over a long period of time was exceptional. Under the unusual conditions that prevailed during the war, the acid was shipped even from the Pacific coast to New York, but since the resumption of normal business, it is now hauled for only comparatively short distances. Moreover, few cargo boats are equipped to transport sulphuric acid in bulk and its corrosive action on metal containers makes it subject to high insurance and freight charges. There is, therefore, little international trade in the acid. Of the 6,407 tons exported from the United States in 1921, 2,895 went to Mexico, 1,389 to Cuba, 722 to Argentina and 110 to Canada.

VIEW OF THE COAL DOCKS AT THE GREAT KRUPP WORKS AT ESSEN IN THE RUHR DISTRICT OF GERMANY

What Is in the Ruhr?

An Attempt to Answer This Question From a Chemical and Industrial Viewpoint, Pointing Out the Economic Significance of French and Belgian Occupation and Possible Effects on the World's Chemical and Metallurgical Industries

WERE the Pittsburgh district to be isolated completely from the remainder of the United States and to be occupied by 50,000 troops and a large technical commission of foreign nationals intent upon controlling production and distribution of that district's basic industries, some idea might be gained of the present situation in the Ruhr district and of its possible economic consequences to Germany and the rest of the world. The Ruhr district is Germany's most important asset—the greatest industrial center of that country, if not of all Europe. From a commercial and economic viewpoint it is to Germany what the Pittsburgh district is to the United States, what the Sheffield region is to England and what the French departments of Nord and Pas-de-Calais were to France before their destruction during the war.

The Ruhr district is not a geographical division of Germany, but geologically it is a well-defined strip of land of about 400 square miles bordering on the Ruhr River. As may be seen from the map on page 341, it stretches across the northern part of the Prussian provinces of Westphalia and Rhineland.

The industrial development of this district may be said to have started about 1850, when coal began to be mined there on an extensive scale. In 1913 something over 114,000,000 tons of coal was mined in the Ruhr district, representing fully 60 per cent of the total German production. As is the case in the Pittsburgh district, the Ruhr does not contain any workable deposits of iron ore, but rather the abundance of coal has been the factor that has made it the principal seat of Germany's iron and steel industries. The industrial centers of Essen, Bochum, Mülheim, Dortmund, Gelsenkirchen, Duisburg, Oberhausen, Ruhrort, Hörde, Witten—to mention only the most important—are the strongholds of Germany's industrial magnates.[1] There Stinnes, the Thyssens, the Krupps, the Haniels, the Kloeckners, the Funkes, play economic roles analogous to those of the Carnegie, Rockefeller, Harriman, Vanderbilt and Gould interests in this country.

Increasing Industrial Population

A very illuminating survey of the economic importance of the Ruhr district was made not long ago by M. Dariac, a special commissioner of the French Government sent into the Rhineland in advance of the French and Belgian troops. He points out that in 1913 the industries of the territory now occupied employed one-fourth of all the factory workers in Germany. This includes 55 per cent of all workers engaged in mining, 27 per cent of those in metallurgy, 20 per cent of the chemical workers and 19 per cent of those in the textile industries.

[1] According to a press despatch on Feb. 13 there were 46,942 French troops (officers and men) in the Ruhr and 12,000 French and Belgian railway men and engineers were at the disposal of the Technical Commission. The position of the troops of occupation was given as follows: Belgian detachment at Sterkrade; 47th French Infantry Division at Recklinghausen; 11th Infantry Division north of Dortmund; 40th Infantry Division south of Bochum; 128th Infantry Division at Essen and south of Essen.

TABLE I POPULATION OF INDUSTRIAL CENTERS IN RUHR DISTRICT

City	Population 1910	Population 1919
Essen	194,653	439,297
Bochum	136,931	144,993
Dortmund	214,226	297,018
Oberhausen	89,900	98,677
Duisburg	218,400	241,788
Gelsenkirchen	169,513	179,785
Herne	57,459	64,135
Recklinghausen	59,283	60,498
Witten	37,450	37,189
Mulheim	112,580	127,353

The Krupp works alone, in 1913 employed 80,000 workers. During the war this number rose to 171,000, but by the end of 1922 had been reduced to about 100,000 employees.

While the total population of Prussia declined from 40,165,219 in 1913 to 36,771,951 in 1919, that of the Ruhr district showed a marked increase, due, probably, to the influx from the territories originally occupied by the Allied troops. The figures in Table I show the extent of this gain in some of the most important industrial centers in the Ruhr district.

An Index of Industrial Activity

An idea of the productive and distributive capacities of the Ruhr district may be gained from statistics of inland traffic, both by water and land. In point of mileage the railroads in the territory now occupied by the French and Belgian troops are but 12 per cent of the total in Germany, but they actually handle practically three-fourths of the traffic of the entire country. In addition, 60 per cent of Germany's water transportation is in the Rhine and Ruhr districts.

Industrial Resources

Coal.—It was previously stated that in past years the Ruhr district has accounted for over 60 per cent of the coal production of Germany. The output of the most important districts in Germany during 1913 and 1919 were as follows (in millions of tons):

	Ruhr District	Upper Silesia	The Saar District	Total for Germany
1913	114 49	43 43	12 22	190 11
1919	71 16	25 93	8 97	116 50

or in percentage of the total:

1913	60 22	22 85	6 43	100 00
1919	61 08	22 26	7 70	100 00

Since the the loss of the Saar basin to France, Germany's coal production has been concentrated in the Ruhr district, so that the present Ruhr output is probably in the neighborhood of 80 per cent of the total. Production during 1921 and 1922, although somewhat lower than the 1913 production, nevertheless considerably exceeds the 1919 figure.

Table III, recently printed in *Coal Age*, shows the total production of the last 2 years as compared with that of 1913.

The coal resources of the Ruhr district from the region that is now producing at the rate of about 100 million tons per year have been estimated[1] to be 31.9 billion tons to a depth of 1,500 m. or 37.5 billion tons to a depth of 2,000 m. The latter amount at the present rate of production would suffice for 375 years.

TABLE III COAL PRODUCTION IN RUHR DISTRICT BY MONTHS

	1913	1921	1922
January	9,786,005	8,072,912	8,132,763
February	9,194,112	8,174,606	7,737,974
March	9,181,430	7,685,185	9,014,278
April	9,969,560	7,894,985	7,512,646
May	9,261,448	6,954,607	8,081,951
June	9,586,385	7,753,350	7,078,361
July	10,150,347	7,782,676	7,864,200
August	9,795,236	8,068,065	8,336,773
September	9,696,397	7,853,871	8,265,688
October	9,895,090	8,047,353	8,837,126
November	8,932,276	7,772,658	8,596,214
December	9,101,858	8,054,517	7,900,000
Whole year	114,550,153	94,114,785	97,350,000

Iron.—The pig-iron production of Germany in 1913 amounted to 19,291,920 tons and was distributed among the various provinces as follows:

District	Percentage
Rhineland-Westphalia	42 5
Siegerland, Lahn, Hesse-Nassau	5 1
Silesia	5 2
Central and eastern Germany	5 2
Bavaria, Wurttemburg and Thuringia	1.2
Saar	7 3
Lorraine and Luxemburg	33 3

Coal-Tar Products.—Before the war the byproduct coke ovens in Germany consumed annually about 45 million tons of coal. Of this amount it was estimated by M. Dariac that 25 million tons came from the Ruhr district. This would account for an output of ammonium sulphate and coal tar in approximately the following proportions:

	Total Production (Tons)	Ruhr District (Tons)
Ammonium sulphate	500,000	400,000
Coal tar	1,200,000	1,000,000

Of this production the Hugo Stinnes group industries accounted for 129,000 tons of coal tar and 69,000 tons of ammonium sulphate.

Situation in the Dye Plants

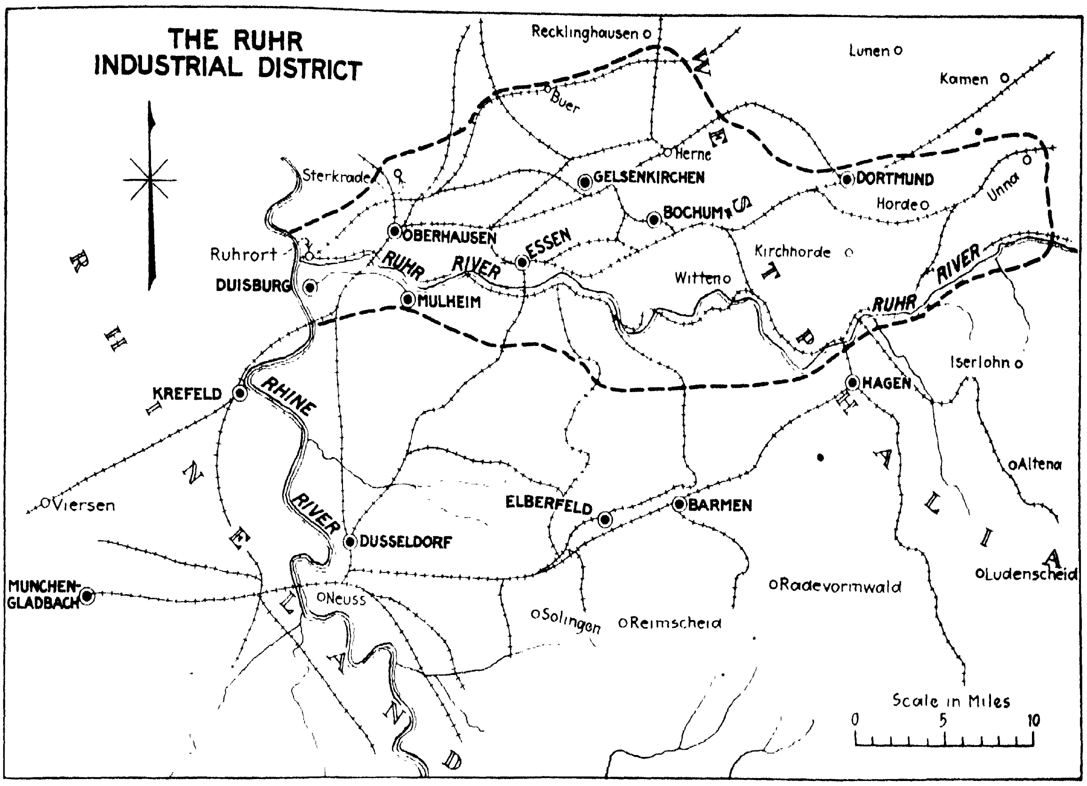
Chemicals.—Practically all of this coal tar passes into consumption in the form of the products of the German organic chemical industries—dyes, pharmaceuticals, color lakes, perfumes, photographic chemicals, etc. However, these industries for the most part lie outside of the Ruhr district as such, although at least 90 per cent of them are included within the territory which has been or is now occupied by the Allies. The great plants of the I.G. (Interessen Gemeinschaft) lie to the south of the Ruhr—Badische at Ludwigshaven-on-the-Rhine, Bayer at Leverkusen, Meister Lucius & Brüning at Höchst-on-the-Main, Cassella at Frankfort and Kalle at Biebrich-on-the-Rhine. Of the less important companies Griesheim-Election is at Offenbach-on-the-Main, Weiler-ter-Meer is at Uerdingen-on-the-Rhine and Leonhardt is at Muhlheim-on-the-Main.

The only important coal-tar dye plant in the immediate vicinity of the Ruhr district is that of Carl Jager, G.m.b.H., Anilinfarbenfabrik at Düsseldorf. This company was founded in 1823 and while small as compared with the ground organizations of the I.G., it is nevertheless a recognized factor in the German industry.

These plants, whether actually within the occupied territory or not, are nevertheless dependent largely on the Ruhr district for their chief raw materials—for coal tar and the so-called crudes form its distillation such as benzol, toluol, naphthalene, anthracene, carbolic and cresylic acids, etc. Naturally the course of their future production will depend on their supplies of these basic materials and for that reason they are vitally affected by the embargoes on coal and coal products which the French are enforcing with increasing severity.

It is scarcely to be believed that the French would voluntarily cut off supplies of these byproducts for any extended period. Little market exists for them elsewhere and from a revenue viewpoint it would be much

[1]"The Coal Resources of the World," vol. III, p. 887 (1913).



MAP OF RHINELAND AND WESTPHALIA, SHOWING THE RUHR DISTRICT AND PRINCIPAL INDUSTRIAL CENTERS

more desirable that they be fabricated into finished products of much greater taxable value. However, the decreasing coking operations due to labor troubles in the coal mines, on the railroads and at the ovens would automatically cut down the supply of raw materials for the dye factories. It is therefore entirely possible that these great industries will eventually come to a standstill unless supplies in the way of coal and coal products can be imported into Germany from England or America.

It has been reported on the authority of high German officials in this country that many of the large dye and chemical factories of Germany now have on hand stocks of crudes and intermediates sufficient to carry them over a period of 4 to 6 months. Just how much credence can be placed in such statements is, of course, largely a matter of conjecture.

Chemical Plants in the Occupied Territory

Names and Addresses of Important Factories in Rhineland and Westphalia and Adjacent Districts, Compiled by Department of Commerce

IN VIEW of the timely interest in the economic and industrial problems arising from the French occupation of the Ruhr Valley in Germany, the Commercial Intelligence Division of the Bureau of Foreign and Domestic Commerce has compiled a comprehensive list of chemical and allied factions within the occupied territory of Germany. This compilation is not as yet entirely complete, but it is believed that its publication, even in fragmentary form, will be worth while at this time. The list follows:

Name	Address	Manufactures
Aachener Chemische Fabrik für Textile Industrie, G m b H	Aachen	Textile chemicals
Aktiengesellschaft für Bergbau, Blei und Zinkfabrikation zu Stolberg und in Westfalen	Aachen	Pig lead, raw zinc, sheet zinc
F D Beizel	Aachen	Varnish and putty
Chemische Fabrik Rhenania, A G	Aachen	Sulphuric acid, muriatic acid, nitric acid, sulphur, barium sulphate and many other chemicals
Chemische Präparate G m b H	Aachen	Pharmaceutical preparations
Chemische und Textileseifen-Fabriken, Charles Schein	Aachen	Textile chemicals
Dr Deckers & Co., G m b H	Aachen	Chemicals and oils
Xav Goblet	Aachen	Soap, fullers soap
S Grauer & Co , G m b H	Aachen	Polishing preparations
Kamps & Janson	Aachen	Oils and lime
Albert Heinrich Kendall	Aachen	Soap and perfume
H Kloke	Aachen	Preparations for the textile industry
Dr Georg Koenig	Aachen	Pharmaceuticals
Cl Lageman	Aachen	Pharmaceuticals
Franz Lauffs	Aachen	Wax candles
Joh Jos Lauffs	Aachen	Wax candles
Medizinal-Werk G m b H	Aachen	Pharmaceuticals
Peter Ney	Aachen	Soap
Jos Preim	Aachen	Perfumery and soap
Reinland & Berns, Chemische Fabrik Optima	Aachen	Chemicals
S Saul	Aachen	Rubber ware
Schleipen & Cie	Aachen	Chemical products
Dr. Schlenter & Baum	Aachen	
Schreiber & Brandt	Aachen	Varnish
A Steenaerts Nachf	Aachen	Soap
H Trommsdorff, chemische fabrik	Aachen	Pharmaceuticals
Gebr Vossen G m b H	Aachen	Dyes
L Vossen G m.b.H	Aachen	Chemicals
Gebr Waeler G.m.b H	Aachen	Chemicals
Georg Heinrich Goebel	Ahrweiler, (Rheinpr.)	Varnish and wood stain
Wilhelm Wirz Nachf. H. Keefer	Ahrweiler. (Rheinpr)	Varnish
Zuendholzfabrik, Albersweiler . Benedick Haupt & Cie.,	Albersweiler (Pfalz)	Match
Eugen Wischner	Altenessen (Rheinpr.)	Chemicals
M. Dietrich	Alzey (Hessen)	Soap
Louis Fritz	Alzey (Hessen)	Soap
Carl M. Diener	Amberg (Oberpfalz)	Wax ware
Boegel & Michel	Annweiler (Pfalz)	

Name	Address	Manufactures
Arienheller Sprudel und Kohlen Saure A G	Arienheller bei Rheinbroh	Carbonic acid, mineral water
Duerkheimer Bade - und Salinen-verein	Bad Duerkheim (Pfalz)	Mother lye, bath salts
D Rathgeber	Bad Duerkheim.	Soap
Rudolf E Linkenbach	Bad. Ems	Soap
Dr Trost Nachf Inh August & Otto Roth, Chemische Fabrik	Bad Ems	Disinfectants and insect powder
Rheinische Kraeuter-Verwortung G m b H in liquidation	Bad Neuenahr (Rhpr)	
Chemische Fabrik Luettgen	Baerendorf b Bochum, Westfalia	
B Amann	Barmen	Dyes
Atlas-Werke Englels & Stracke, G m b H.	Barmen	Chemicals
Bayrisch-Rhein Farbenfabriken Knechtchel & Co	Barmen	Dyes
Bruno & Hoefinhoff	Barmen	Photographers' suppl's
Chemische Fabrik Einergraben	Barmen	Acid
Carl Dicke & Co, Chemische Fabrik	Barmen	Ferrous sulphate
W. Kopp	Bendorf a Rhein	Inks
Friedr Wilh, Remy & Cie	Bendorf a Rhein	Varnish and lead colors
Rheinische Gerbstoff-und Fabrholz Extract Fabrik, Gebr Mueller A G	Benrath (Rheinpr)	Tannic acid
Bensberg-Gladbacher Bergwerks und Huetten A G Berzelius	Bensberg (Rheinpr)	Lead, zinc ore and sulphuric acid
Bensberger Chemische Fabrik August Boeringer	Bensberg (Rheinpr)	Varnish, lacquer
Zuendertabrik Bensberg, G m b H	Bensberg (Rheinpr	Matches
Ceromitgesellschaft m b H	Bergisch-Gladbach	
Sprengkapsel-Fabrik Olpe G m b H	Bergisch (Rhpr)	
A W Andernach	Buel (Rhpr)	Asphalt and roofing supplies
Chemische Werk "Concordia" G m b H	Beuel (Rhpr)	Pharmaceutical prep
Dr Lambotte & Schattenverg G m b H	Buel (Rhpr)	Colors, varnish
Dr L O Marquart	Buel (Rhpr)	All drugs, acids, etc
Vaseline-Fabrik Rhenia, E Waserfuhr	Buel (Rhpr)	Vaseline
Brandscheid & Weyrach	Biebrich a R (Hess -Nass)	Varnish
Chemische Fabriken Dr Kurt Albert	Biebrich a R (Hess -Nass)	Organic chemical prod.
Chemische werke vorm H & E Albert	Biebrich a R (Hess -Nass)	Artificial fertilizers
Adam Hofmann	Biebrich a, R (Hess -Nass)	
Kalle & Co , A G	Biebrich a R (Hess -Nass)	Coal tar dyes, pharmaceutical preparations
Dr Th Steinkauler, Victoria, Vaseline-Fabrik	Biebrich a R (Hess -Nass)	Vaseline, oils, etc
Teerproduckten Biebrich, Seck & Dr. Alt, Jean Scholl	Bingen a R	Soap
Gebrueder Bier	Birkenfeld (Fuerstentum)	Perfumes and soap
Chemische Fabrik, Walter Bosch, G.m b H	Bochum (Westf)	Technical oils, fat
Chemische-Industrie, Act -Ges	Bochum (Westf)	Tar distillery, sulphuric acid, nitric acid
Deutsch Luxemburgische Bergwerks und Huetten A G	Bochum (Westf)	Benzol, tar, and ammonia
"Farbenmueller" Gesellschaft, G m b.H	Bochum (Westf)	Dyes
Gruemer & Grimberg, G m b H	Bochum (Westf)	
C. Jungkenn, G m.b.H	Bochum (Westf)	Varnish, lacquer and tar
Kupferhuette Bochum, G m b H	Bochum (Westf)	Copper and pyrites
Alf Lewin	Bochum (Westf)	Pharmaceuticals
Joh. Chr Leye G m b H	Bochum (Westf)	Asphalt, tar and rosin
Theo Schuecking	Bochum (Westf)	Oils
Westfaelische Zuendwaren Industrie, G m b H	Bochum (Westf)	Explosives, matches, etc
Zeche Ver Carolinenglueck	Bochum (Westf).	Technical fats
Bach & Bruecken	Bonn a R	Varnish
Carl Blank	Bonn a R	Bandages, rubber plaster
Bonner Chemischer Industrie, G m b.H	Bonn a R	Special soap, varnish
Gebr. Bornefeld	Bonn a R	Varnish
de Foy & Finking	Bonn a R	Varnish
Joh Hanstein	Bonn a R	Varnish and colors
Hoffman & Dewald	Bonn a R	Varnish
Kleine & Flume	Bonn a R	Artificial mineral water
J. W Pfankucken Sohn	Bonn a R	Ink powder
Pharmazeutische Fabrik Stein	Bonn a R	Hygenic rubber goods
Dr Pitschke's Chem Laboratorium	Bonn a R	Pharmaceuticals
Dr Schuetz & Co	Bonn a R	Pharmaceuticals
Schmithausen & Co	Bonn a R	Pharmaceuticals
Adam Segschneider	Bonn a R	Wax candles, tapers
Wilhelm Vollmar	Bonn a R	Waxen goods
Thomasschlacken-Mahlwerke Oberhausen, Gesellschaft m b H	Borbeck (Kr Essen)	Fertilizer
Fabrik-Chemische-Technischer Producte, Phillip Frank	Boppard (Rhpr)	Technical oils and fats
Pharmazeutische Fabrik Asta, G.m b.H	Boppard (Rhpr.)	Pharmaceuticals
Chr Rath	Boppard (Rhpr)	Soap, glycerine
Herm. Renckhoff	Boppard (Rhpr)	Pharmaceuticals
"Reinland" Fabrik für Asphalt pappe, Teer und chem Produkte G m b He		
Wilhelm Genenger, Nachf.	Breyll (Rhpr)	Asphalt, tar paper
Chemische Fabrik Bruehl Gottfried Kentenich & Co , m b H.	Bruehl (Bz Koln a, R)	Soda, rosin
Kohlensaeurewerk Burgbrohl G m b H	Burgbrohl (Rhpr)	Natural carbonic acid
Gebr Rhodius	Burgbrohl (Rhpr)	White lead, carbonic acid
Gustav Rhodius	Burgbrohl (Rhpr)	Chemicals
Fabrik pharmazeutischer Praeparate, A Stein	Burgwaldniel a Niederrhein	Pharmaceuticals
Bergische Kerzenfabrik G m b H.	Burscheid (Bz Dusseldorf)	Candles
Rheinische Kerzenfabrik August Pfeiffer	Burscheid (Bz Dusseldorf)	Candles
Clever Oelmuehle, G m b H	Cleve (Rhpr)	Linseed and rapeseed oil
Clivia Oelwerke, G m.b H	Cleve (Rhpr)	Linseed and rapeseed oil
Chemische Fabrik, Coblenz-Wallersheim, G Wilckens Nachfolger, Dr Kretzer	Coblenz a, R.	Fluorine, cobalt, etc.
Chemische Fabrik Luetzel G m b H	Coblenz a/R	Chemicals
Chemische Werke Rombach G m b H	Coblenz a/R	Chemicals
Louis Fischer	Coblenz a/R	Soap, candles
Franz Goerger	Coblenz a R	Waxen goods
Hermann Josef Krepele	Coblenz a/R	Soap
Radium Gummiwerk G m.b.H	Dellbrueck (Bz Koln)	Soft rubber goods
Thomas schlacken-Mahlwerk, G m b H	Dillingen a d Saar, (Rhpr)	Fertilizer
Rheinische Fabrik fuer Elektrische Bogenlichtkohle "Excelsior," W Gruedlbach	Dinslaken (Niederrhein)	
Gebr Mueller	Dorsten (Westf)	Soap powder
J E Ausbuettel	Dortmund	Surgical dressings
Franz Brunck	Dortmund	Tar and ammonia
Chemische Fabrik, Theo. Fincke	Dortmund	
Chemische Industrie Funk & Cie	Dortmund	Rosin, technical oils
Dorner Oelwerke, Creamer & Dahlmann	Dortmund	Oils
Dortmunder Thomasschlacken Mahlwerk, G m b H	Dortmund	Fertilizer
Th Fahnenstich Soehne	Dortmund.	Tar and roofing prod.
Heinr Flev	Dortmund	Soap
Dorstfeld Gewerkschaft	Dortmund	Ammonia, benzol, tar
Hermann Haueisen	Dortmund	Oil colors, varnish, putty
Wilh Klaas Soehne	Dortmund	Asphalt
H & E Kruskopf	Dortmund	Chemicals
Rud Kuepfer	Dortmund	Tar products
G & W Lambeck	Dortmund	Chemicals
Herm Meier	Dortmund	Soap, candles
Herm Meininghaus, jun	Dortmund	Soap, glycerine
Richard Meyer	Dortmund	Dyes
Moritz Nake, Dortmunder Kohlen-anzünder-Fabrik in Dortmund,		
Wilh Pahl, Dortmunder Gummiwaren Fabrik	Dortmund	Technical rubberware
C B Ranke, G m b H	Dortmund	Asphalt, tar products
Fr Sobbe, G m b H	Dortmund	Electric lighters
Ueter & Grenzdorfer G m b.H	Dortmund	Colors, varnish
Vereinigte Asbestwerk Danco, Wetzol & Cie , Gesellschaft m b H	Dortmund	Asbestos products
Westdeutsche Sprengstoff Werk, A G	Dortmund	Explosives
Westfaelische Essenzen-Fabrik, G m b H	Dortmund	Essences
Westfaelische Mineralöl, W H Schmitz	Dortmund	Resinous products, technical oils, and fats
J Beckers & Cie	Dueren (Rhld)	White lead
Brüning & Soehne	Dueren (Rhld)	White lead
Gebr Caesar	Dueren (Rhld)	Asphalt, tar
Chemische Fabrik Durania	Dueren (Rhld)	Chemicals
Chemische Fabrik K.Jas	Dueren (Rhld)	Chemicals

Regional Meeting at Chicago A.S.S.T.

Measurement of Cooling Rate; Its Effect on Structure of High-Carbon Steel; Microphotography and Metallurgical Education Hold Attention of Members

PURSUANT to their admirable plan, the various local organizations near by Chicago united in a regional meeting on Feb. 8. Two technical sessions were held during the afternoon and evening, while the social animal was appeased by luncheon and supper served at the City Club. On the following day many members and their guests made inspection visits to nearby steel works or forge plants. In this way many men who have not the means or the opportunity to attend one of the national conventions held by the American Society for Steel Treating in some distant city can participate in all the convention activities near at home at least once a year.

Brief notes on the formal papers read at the session appear below.

Hot Bodies Cooling in Air

E. J. Janitzky, metallurgist of the Illinois Steel Co., noticed that cooling curves assume a shape approximately that of a rectangular hyperbola, and upon investigation found this indeed to be a fact. When plotting time against temperature at the center of a ⅞-in. cylinder of high-nickel steel 2½ in. long, cooling in air, he found that the correspondence was extremely good, and since then he has checked the same relation for very large masses, such as ingots or annealing furnaces, and has verified the assumption by figures already published by various investigators.

The entire matter can be generalized if a rectangular hyperbola be plotted, having the x axis as one asymptote, and the ordinate y — — 1 as the other. The equation for this curve is

$$y = \frac{K}{x + 1}$$

K is the intersection with the y axis and represents the temperature of the body at the beginning of the cooling; y is the temperature of the body at any time thereafter. The unit of x is the "time constant," or the time required (in minutes, seconds or hours) to cool the body half way to zero.

As an instance, for the small nickel steel specimen cooling in air at 80 deg. F., it required 4.7 minutes to cool from 1,750 to 875 deg. F. Call this time the first period. During the second period (or at the end of 9.4 minutes) it will cool to

$$y = \frac{1750}{2 + 1} = \frac{1750}{3} = 585 \text{ deg. F.}$$

At the end of the third period it will cool to ¼ of 1750 or 437, of the fourth period it will be at ⅕ of 1750 or 350 deg. F. and so on.

Computed and actual results follow:

	Pyrometer	Calculated	Time Interval x	Time Interval Minutes
Original temperature	1750		0	0
	875	875	1	4 7
	580	585	2	9.4
	445	437	3	14 1
	340	350	4	18 8
	285	290	5	23 5
	240	250	6	28.2

The matter of predicting the approximate time when the body will reach a given temperature resolves itself into a very simple arithmetical calculation, requiring only the experimental determination of the time required to cool one-half the distance to zero. This time (the "time constant") evidently varies with the material, its shape, mass and temperature to which heated; it cannot easily be predicted, but can very easily be measured.

If the cooling is delayed by transformations in the body—as for instance steel at the recalescence point—the cooling is merely interrupted the time necessary to complete the transformation—that is to say, the y axis is shifted to the right an equivalent amount.

Technique of Microphotography

An interesting set of micros, taken at very high magnifications, were shown by R. G. Guthrie, of the People's Gas Light & Coke Co., while recounting some of the precautions necessary before such work can be successful. He also cited the methods of producing sensibly monochromatic light and the reasons for its utilization; ray filters recommended by the manufacturers of the particular plates used by the operator will usually be most satisfactory. While a single filter will cut out a large number of wave lengths, a combination of two or more will be found very useful to narrow down the transmitted beam. He regards the panchromatic plate as the ideal for many purposes, despite the fact that it must be handled with the greatest care, owing to its sensitivity to infra-red rays.

In experimenting with polarized light, he attempted to use it in an ordinary Leitz metallurgical microscope to photograph opaque specimens. He mounted the polarizer just ahead of the sub-stage condenser, and the analyzer in the tube carrying the ocular. Using sensibly monochromatic light, it was easy to photograph the structure in its usual aspect when the prisms were set parallel to each other. Crossed Nichols should have showed the field dark, which was found to be true only when the beam consisted of an extremely small pencil of rays. Opening the diaphragm somewhat allowed a photograph to be made of the structure in extremely curious contrast, suggesting a badly overexposed print on blueprint paper. While the speaker was unable to point to any present utility of the method, it seemed to be in effect an example of the possibility of photographing metallic specimens at high magnifications and under oblique illumination—polarized light being essentially that.

Education

Remarks on the ways and means of capitalizing upon metallurgical achievements were made by E. E. Thum, associate editor of *Chemical & Metallurgical Engineering*. Noting that while there is doubtless much pseudo-engineering masquerading as technical control, a successful metallurgical or testing department was bound to contribute toward a reduction in manufacturing costs. The problem then is properly to show these savings in a way that the auditor, the manager and his board of directors cannot help but see. When that has been done, their services will be valued in direct proportion to the amount of profit they can show—they will become something more than a salary expense.

After recounting the wide variety of activities and interests occupying their attention, the speaker recommended that the best way to sum all these things in the ledger was to have a departmental account started for the testing or metallurgical department. Then it would be possible to charge the various manufacturing departments for services rendered at a fair rate, and to secure the proper book credit for new developments and econ-

omies suggested in the operations. These will easily be found to overbalance the salaries and expenses of the necessary investigations.

STRUCTURE OF HARDENED HIGH-CARBON STEEL

A 1.78 carbon steel, quenched from 1,080 deg. C., was examined by Howard Scott of the Bureau of Standards. He found the interior to consist of good-sized polygonal grains, shot through with feathery needles (plates) and containing a little massive cementite at the grain junctions—evidently unabsorbed excess constituent. Some decarbonization occurred at the very surface, since there was no massive cementite observed in the microsection; the appearance there was a typical granular martensite of hardened tool steel. In a thin intermediate zone the polygonal grains characteristic of the center contained zigzag apparitions, like lightning flashes, and few if any needles.

The interior grains are thought to be austenite, because they have a simple polyhedral outline. It is plastic, because squeezing in a vise developes twins and slip bands. Cooling to liquid air buckles the surface and develops a structure suggestive of martensite. When cooled from 1,080 slowly—i.e., in a mild air-blast—it develops small areas of a dark-etching constituent like troostite, and the grains completely transform to this material on tempering at 350 deg. C.

Massive cementite, free at the grain boundaries and envelopes, is easily identified by its characteristic color and shape and by darkening after the sodium-picrate etch. Feathery needles (plates in three dimensions) also etch dark in sodium picrate; they usually grow from the grain envelopes, and spheroidize on tempering to 600 or 700 deg. C. Scott therefore dubs them cementite, soluble in austenite at 1,080, but precipitated along cleavage planes during cooling.

Zigzags are thought to be thick plates of martensite. They appear in the austenitic grains after cooling in liquid air. On tempering to 250 deg. C. they etch much quicker, and when the structure is tempered to 600 deg. C. and becomes sorbite, the needles persist as white ghosts, and contain fewer cementite particles than their surroundings. Sometimes they occur in the same grain with a broad-banded twin, from which they can be easily distinguished by form and etching characteristics.

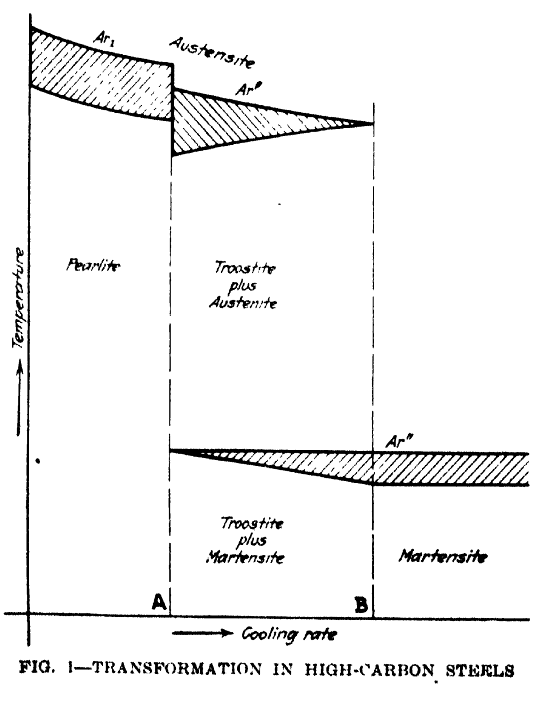

FIG. 1—TRANSFORMATION IN HIGH-CARBON STEELS

If these conclusions as to the identity of the structural constituents are correct, it follows that in a very high-carbon steel quenched from a very high temperature, an austenitic core is produced at a moderately slow cooling rate—slower in fact than that producing martensite in the lower-carbon steel at the edges. Furthermore, this austenite appears to transform directly into troostite (by slower cooling or mild tempering) without any intermediate martensitic stage appearing.

Such facts are generalized in a diagram of the "stepped" transformation (Fig. 1) as indicated by many recent researches on quenching. A eutectoid steel, cooled slowly, or at a rate less than that indicated at *A*, will transform abruptly at Ar_1 (in the neighborhood of 650 deg. C.) from austenite into pearlite. At somewhat faster rates, the transformation appears to split; some austenite appears to change to troostite at Ar' (650 deg. C. $\pm$) and the rest into martensite at Ar'' (250 deg. C. $\pm$). The final structure of eutectoid steel is a mixture of troostite and martensite. If the steel contains much more carbon, as the 1.78 C steel under discussion, and is quenched from a high heat, Ar' and Ar'' are lowered, Ar'' occurring below atmospheric temperature and therefore suppressed. Then the steel will be austenitic with some troostite. Supercooling in liquid air passes Ar'', and develops the structure expected in a eutectoid steel. For very rapid rates of cooling the steel is either austenitic or martensitic, depending upon whether Ar'' is above or below the lowest temperature attained during the quench.

Quenching experiments with lower-carbon steels—containing 1.16 and 1.04 per cent carbon respectively—were made to discover the rate at which the cooling must be effected in order to preserve the martensitic structure (*B* of Fig. 1). These developed a number of surprises, most notable of which is that it is easy to produce a specimen possessing a martensitic core and a muff partly or entirely of troostite. Evidently some other factor than rate of cooling is responsible for the ultimate structure. Consideration of the facts in this case led the author to discuss the effect of internal stress upon the transformations found in steel.

Mathematical analysis of the cooling at various regions in a steel ball was given to show how the rate of cooling, and therefore cooling stresses, varied at different times during the cooling. In this way it was possible to show that quenching from a high temperature at certain rates will throw high tensions in certain regions. Since the transformation austenite → troostite involves an increase in volume, pressure will lower the temperature at which it occurs (Ar') or restrict the transformation, and conversely tension will increase it, and cause troostite to appear in considerable masses where only austenite would be expected from a consideration of cooling rates only.

Production of Talc in Canada

In a report just published by the Canadian Department of Mines, the production of talc in Canada in 1920 amounted to 21,000 tons. Virtually the whole of this quantity was derived from the Madoc area of Onartio.

How to Save Money by Proper Methods of Barrel Handling

The Right and Wrong Methods of Storing Barrels Are Both Pictured and Described — A Number of Generalizations on the Care of Barrels Are Then Derived From the Examples

BY MATTHEW WILLIAM POTTS
Consulting Engineer, New York City

IN PREVIOUS article,[1] on "The Dollars and Cents of Careful Barrel Handling," we merely led up to the most important point—namely, the storage of barrels. The amount of care taken in storing, handling and filling of barrels has a great deal to do with the method of storage and the ultimate success or failure of the barrels as containers, providing it is necessary to store them for any length of time after they have been filled, and also has a great deal to do with how the barrel will stand up in storage after it is received at the consumer's plant.

There are certain fundamentals in barrel storage that apply in both the manufacturer's plant and the consumer's plant. Each branch of the industry has certain requirements that must be met. The pertinent questions which apply in most cases are:

1. How are the barrels received at the storage warehouse—i.e., conveyors, hand trucks, tractors and trailers, motor trucks, railway sidings, etc.?
2. How long will the barrels remain in storage?
3. What is the nature of their contents—i.e., liquid, powder, dangerous, neutral?
4. How many different products are to be stored?
5. Is there more than one grade of the same product—for instance, chemicals of different analysis?
6. How must the materials be taken out of stock—i.e., must the oldest stock be taken out first?
7. Is storage space plentiful or must every cubic foot be utilized?
8. Is it necessary to take a complete physical inventory? If so, how often?

There are numerous other questions which will present themselves such as, Is the warehouse space all on one floor, or on different floors which would necessitate the use of elevators? What is the allowable floor load? This last question will regulate the height of piling. It is difficult therefore to go into detail unless we could take into consideration some particular

[1] Chem. & Met., vol. 28, No. 7, Feb 14, 1923

FIG. 6—HOW NOT TO STORE BARRELS
Here is shown poor aisle space, absence of dunnage and thirty varieties of commodities. Question: How would you get at barrel "A"?

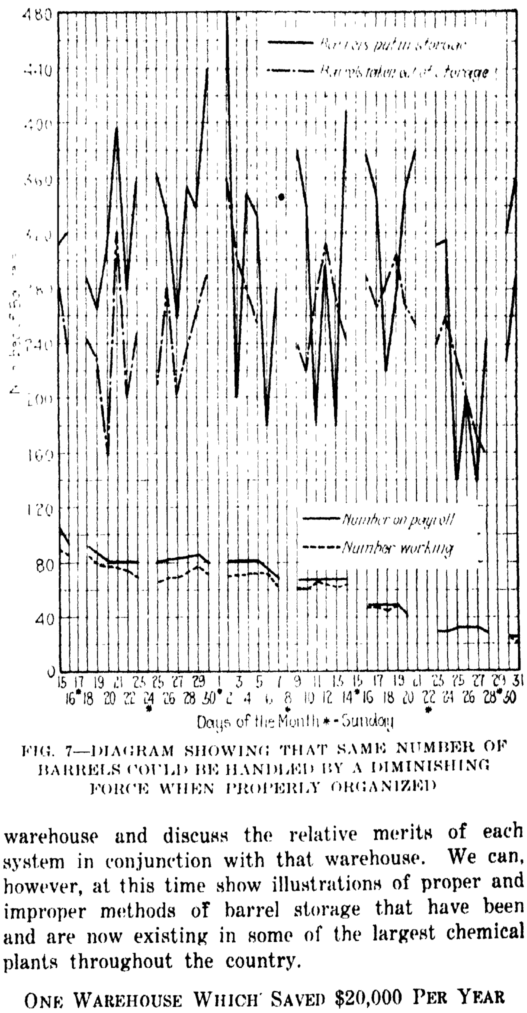

FIG. 7—DIAGRAM SHOWING THAT SAME NUMBER OF BARRELS COULD BE HANDLED BY A DIMINISHING FORCE WHEN PROPERLY ORGANIZED

warehouse and discuss the relative merits of each system in conjunction with that warehouse. We can, however, at this time show illustrations of proper and improper methods of barrel storage that have been and are now existing in some of the largest chemical plants throughout the country.

ONE WAREHOUSE WHICH SAVED $20,000 PER YEAR ON BARREL HANDLING

In the warehouse one of the most important points to consider is the layout of aisles; next, the piling of the barrels; third, the proper method of building the piles. Looking at Fig. 6 we see a condition that exists in over 50 per cent of the chemical plants throughout the country. This is a poor and wasteful method of storing barrels. First, there is poor aisle space; this runs up the labor cost. Second, there is no dunnage between the tiers of barrels; this causes damage to the heads of the bottom barrels and also runs up the labor cost. Third, the group contains about thirty different products, and the one marked *A* might be required first. There is also waste overhead space which could be utilized with a proper layout. When we consider that this same condition existed throughout 40,000 sq.ft. of floor space, we can picture a real problem. Only

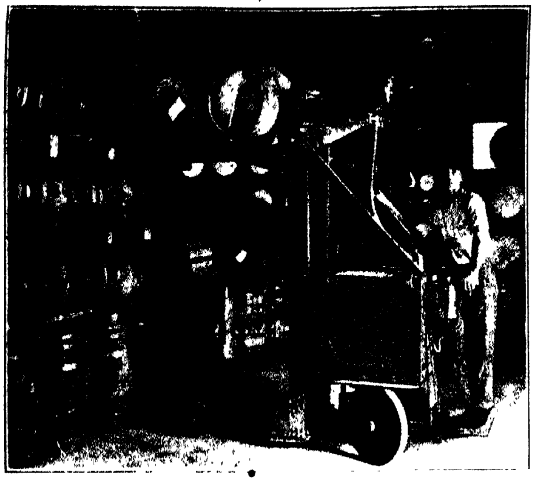

FIG. 8—TIERING TRUCK HANDLING AND PILING BARRELS OF LEAD OXIDE. AVERAGE WEIGHT OF BARREL 1,100 LB.

imagine the overhead space that could be utilized if the layout was proper. Taking this condition and making a rearrangement of aisles and products, the writer was able to reduce the labor force from fifty-three men to thirteen men in a month and a half; increase the capacity of the warehouse 50 per cent; and at the same time handle more barrels.

The trend of the improvement and the number of barrels handled per day are shown in Fig. 7. By adding the number of barrels put in storage and the number taken out of storage the reader can easily find the total number of barrels handled per day. For instance, on the 31st, or the last day shown on the chart, there were thirteen men working. These men placed 360 barrels in storage and removed 290 barrels from storage, making a total of 650 barrels handled in a 9-hour day. These thirteen men include the foreman, checkers, coopers and painters, but do not include the office force.

The main point in reducing the force was the layout of aisles, but the use of electric tiering machines played an important part also, and the installation of a ramp conveyor to carry the barrels to the car-loading platform was another great assistance. The new arrangement permitted the barrels to be tiered four high on the chimb.

This reduction in the force of labor required had several advantages. First, it reduced the payroll by $24,960 per year. The new equipment cost $5,000, so this meant a saving of $19,960 in the first year over and above the cost of the equipment. Second, it eliminated considerable labor trouble and made supervision easier, as thirteen men are easier to handle and keep satisfied than fifty-three men.

Three Methods of Storing Barrels

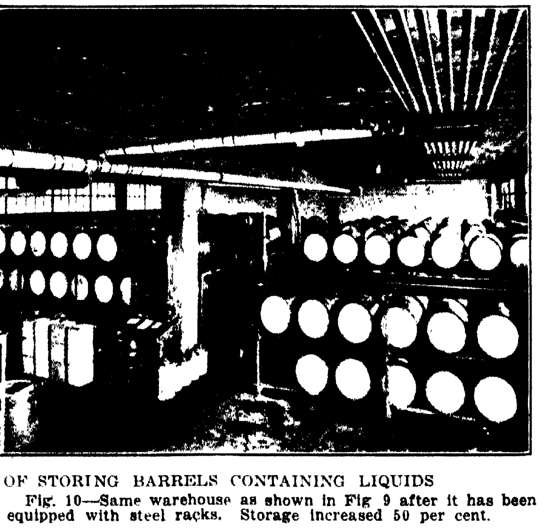
Looking at the problem of barrel storage in general, whether the amount stored is a small or a large quantity, there are only three distinct methods of storage. The best method to be used depends upon whether the product being stored is in dry or liquid form, and not on the quantity to be handled. The three methods are here given in their order of preference:

1. In racks on the bilge. (See Figs. 10 and 14.)
2. On the bilge with dunnage. (See Fig. 9.)
3. On the chimb with dunnage. (See Fig. 12.)

The rack system of storing is without a doubt the best method, as it allows systematic storage by groups, products, analysis, etc. The separate tiers makes lotting of stock simple, convenient and inexpensive. Each tier of barrels is separate and accessible, being held free from those above and below. This allows considerable flexibility of storage space and prevents pressure on the lower tiers—pressure which with the other methods results in parting of the staves and leakage.

With the rack system it is possible to take a complete physical inventory at any time, as all barrels are easily reached by leaving a foot of space between racks. If it should become necessary to remove any particular barrel it may be done easily, whether the barrel is in the uppermost or in the lowest tier, and at a minimum expense. Another advantage is the ability to utilize all overhead space. With racks it is possible to tier barrels as high as ten tiers or to a height of over 20 ft.

If the barrels contain liquids, it is often necessary to turn them slightly so as to keep all sides moist and prevent loss of content, through staves that have dried out, when the barrel is removed from stock. With the rack system this turning can be frequently done with little expense and effort.



FIGS. 9 AND 10—PROPER AND IMPROPER WAYS OF STORING BARRELS CONTAINING LIQUIDS

Fig. 9—All barrels should be stored on the bilge. The method of dunnage shown is correct.

Fig. 10—Same warehouse as shown in Fig. 9 after it has been equipped with steel racks. Storage increased 50 per cent.

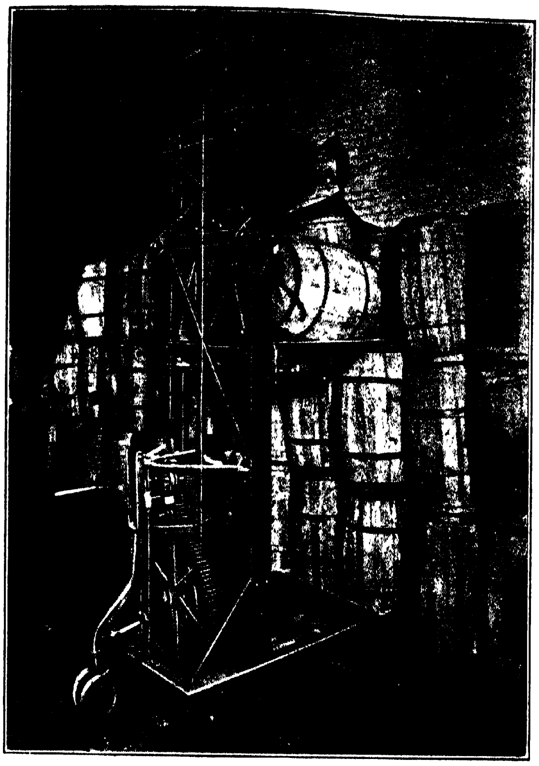


FIG 11 IMPROPER METHOD OF PILING BARRELS
Note uneven piles, which results in accidents. See text regarding position of tiering machine.

The economical advantage of the rack system is the small labor force required to operate a warehouse where racks are installed. In most cases one man with a portable elevator (or tiering machine) can do all the work of placing and removing the barrels from stock.

It is true that barrels can be stored without being placed in racks, but they will not be as accessible and there is more chance of damaging the barrels. Looking at Fig. 8 we see a good method of handling, tiering and storing barrels except that the bottom tier should be on the bilge and resting on dunnage placed on the floor. We can agree, however, that it would be impossible to remove the bottom barrels without taking down the whole pile. This means that this system is useful and practical only where the products are all the same grade. It would be impossible to pile the barrels in this manner if they contained liquids, as the excessive pressure would spread the staves and cause leakage. In this warehouse, if liquids were being stored instead of dry products, it would be impossible to pile the barrels more than two high, and the remaining 8 ft. of headroom would be wasted.

Fig. 9 shows the proper way to store barrels containing liquids, providing dunnage is being used in place of racks. Note the dunnage on the floor, which gives two points of contact on the staves of the barrels instead of placing all the pressure directly on the bilge. The two points of contact also hold the barrels steady and prevent accidents from a wabbly pile. The dunnage for the second tier is also shown. It is not recommended to pile liquids over two high with this system, but barrels containing dry products can safely be piled as high as four tiers.

Fig. 10 shows the same warehouse equipped with racks. Note the additional increase of 50 per cent by adding the third tier of barrels. If this warehouse had been built with the idea of using racks, a slight rearrangement of the overhead steam pipes would have permitted the placing of a fourth tier, which would have allowed an increase of 100 per cent over the old method. This photograph shows very clearly the narrow aisles that are possible with the use of racks and also how the bottom barrels can be removed without disturbing the upper tiers.

Practice in Handling Slack Cooperage

The illustrations so far have shown only tight cooperage. Figs. 11 and 12 show two ways of storage, a proper and an improper method. While these photographs show slack cooperage, it is only incidental.

Looking at Fig. 11 we see a good example of how not to pile barrels and also the wrong way to use a portable elevator (or tiering machine). First, there is no dunnage between tiers* of barrels; this makes a very unsteady pile which is dangerous and does not permit of the full use of the overhead space. If dunnage had been placed in this pile, it would have been possible to pile the barrels four high, thus increasing the storage capacity by 33⅓ per cent. It is plain to see that some of the barrels are resting directly on the heads of those beneath; this often causes breakage of the heads. The portable elevator should be placed with the pile or at right angles to the position shown in order to operate efficiently. Placed in its proper position the machine will work in narrower aisles and the barrels can be rolled on from the front of the machine and off at either side without moving the machine. This important point is often overlooked.

Fig. 12 shows the proper way to pile barrels and

FIG. 12—PROPER AND EFFICIENT METHOD OF PILING BARRELS CONTAINING DRY PRODUCTS

also the proper position of the portable elevator in relation to the pile. Note the dunnage beneath the bottom barrels so as to allow the moisture from the floor to escape, thus eliminating the swelling of the bottom heads. Observe the straight even piles, the placement of the dunnage, the nearness of the portable elevator to the face of the pile and the number of men used in piling this material.

Fig. 13 shows the wrong way to place a portable elevator and also shows how the contents of the barrels leak out between the staves when they are stored on the chimb. Fig. 14 illustrates the use of the rack system and the proper placing of the portable elevator when it is used in conjunction with racks. Note how some of the barrels from the bottom tiers have been removed without disturbing the upper tiers.

There are a number of points which have not been touched in this article, and a number that are found only in certain branches of the chemical industry. It will be found advantageous by most companies to look over their present methods of barrel storage and to correct the faults set forth in this article. It will also pay to have their engineering department or an outside consulting engineer make a study of their barrel storage. Often little items that are being daily overlooked will amount to a loss of thousands of dollars per year that could be saved without a very large investment. Under this heading comes the matter of space. Are you getting the maximum amount of storage possible in a given space?

A Few Axioms in Barrel Handling

In conclusion a few general points about the handling and storage of barrels should be listed and followed to obtain the maximum results and possible economies.

1. Keep the barrels dry; never leave them outdoors even for an hour without covering.

2. Never store barrels in a draught, in a sunny room, in a wet cellar or where temperature is in excess of 60 deg.

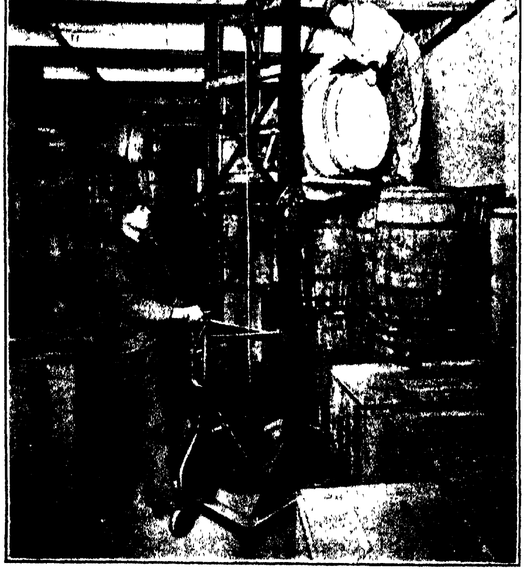

FIG. 13—POOR LAYOUT OF WAREHOUSE AND AISLES
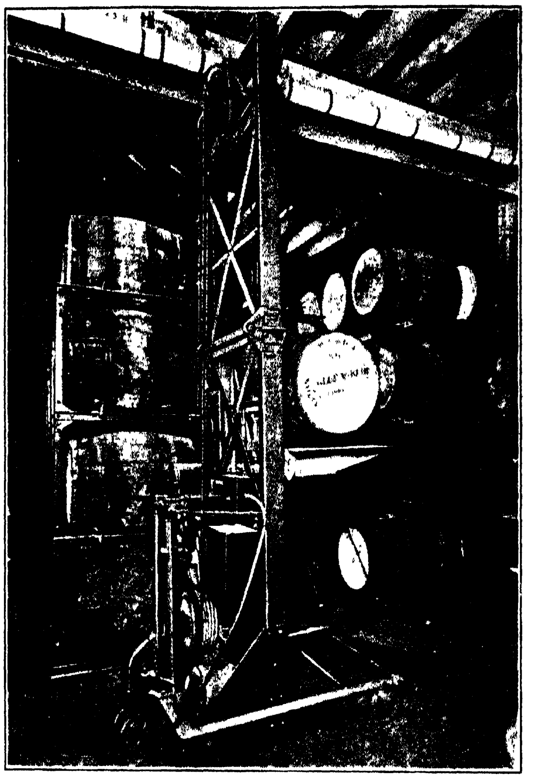
Note contents of barrels leaking between the staves.



Courtesy of the Economy Engineering Co

FIG. 14—EXCELLENT LAYOUT OF BARREL RACKS
Proper method of storing barrels and proper location of tiering machine in placing barrels.

3. Maintain an even temperature in the warehouse.

4. Always store on the bilge with the bung stave up. This is the weakest stave in the barrel.

5. Never store on the chimb without placing dunnage between tiers.

6. Always cooper barrels by machinery. It gives a better and tighter job.

7. Never drop a barrel. To do so may break the staves.

8. Use a paper lining in barrels containing dry products.

9. Size (line) barrels that will contain liquids to prevent the wood absorbing the product.

10. Never fill barrels with products that are hot. The barrel will expand and develop leaky joints as soon as it cools.

Coke Byproducts of 1922

The U. S. Geological Survey has issued preliminary statistics indicating a production of 28,493,000 tons of byproduct coke and 8,033,000 tons of beehive coke during 1922. On the assumption that the yield of byproducts from coke ovens in 1922 bore the same relation to the coke production as in 1921, the following recoveries of various products are estimated:

Tar, gal.	365,000,000
Ammonia (sulphate equivalent of all forms), lb.	946,000,000
Gas M. cu ft.	447,000,000
Crude light oil, gal.	111,000,000

The Survey has issued preliminary figures by states and by months as a part of a recent weekly coal report. Those desiring these data can secure them on application to the Survey, Washington, D. C.

The Chemical Engineer's Part in the Rescue Work at the Argonaut Mine Disaster

How the Composition of Escaping Gases Was Used to Follow Progress in Controlling the Fire —Estimate of Extent of Destruction Based on Gas Analyses*

BY L. H. DUSCHAK
Chemical Engineer, San Francisco

WHEN the fire was discovered in the vicinity of the 3,000-ft. level of the Argonaut shaft in California shortly before midnight on Aug. 27, 1922, the mine was being ventilated in the usual manner by an exhaust fan situated near the collar of the Muldoon shaft, which with the communicating system of raises and connections formed the return airway. As no change was made in the system of ventilation after the fire started, a dense cloud of smoke was soon emitted by the fan. This continued for about 3 hours, after which the density of the smoke cloud materially decreased, but the fan discharge was still of a highly toxic character. Owing to the limitations of the oxygen-breathing apparatus, any attempt to reach the working levels of the mine through the Muldoon system was out of the question as long as the Muldoon atmosphere remained irrespirable. An accurate knowledge of the condition of this atmosphere was therefore essential in planning the rescue program.

Regular gas sampling at the Muldoon fan was commenced on Wednesday morning, Aug. 30. A typical analysis was as follows: O_2, 17.6 per cent; CO_2, 2.8 per cent; CO, 0.7 per cent. Analyses were made with a standard Orsat apparatus, following the procedure outlined by Kreisinger and Ovitz.[1] Carbon monoxide determinations were also made with the carbon monoxide detector,[2] manufactured by the Mine Safety Appliances Co. At this time the churning of the fan indicated that it was handling much less than the normal volume of air.

During Wednesday and Thursday the composition of the fan discharge remained practically unchanged, indicating that the efforts to extinguish the fire were unavailing. Exploration made Thursday afternoon by an apparatus crew under the direction of B. O. Pickard of the U. S. Bureau of Mines disclosed burning timbers below the 2,500-ft. level. These were extinguished without producing any material change in the gas discharged by the fan and it was evident that a vigorous fire was still burning considerably below this point. On Friday it was decided that further efforts to extinguish the fire by the application of water from above were useless and a tight bulkhead was constructed across the shaft below the 2,500-ft. level. Bulkheads in the drifts on the 2,400- and 2,500-ft. levels were also repaired and sealed with clay in order to prevent any fresh air from reaching the fire zone. The efficacy of these bulkheads was shown by an almost immediate decrease in the quantity of CO_2 and CO in the fan discharge.

On Sunday, Sept. 3, an exploring party crossed from the Argonaut shaft to the Muldoon end of the 2,400-ft. level. The raise coming up to this point carried all of the gas escaping from the lower levels of the mine. A sample taken at that time with the apparatus shown in Fig. 1 and analyzed later in the usual way had the following compositions: O_2, 13.0 per cent; CO_2, 6.2 per cent; CO, 0.9 per cent. A comparison of this and subsequent samples at this point with samples taken at the fan showed that between the 2,400-ft. level and the surface, the gas coming from the lower levels of the mine was diluted with approximately twice its volume of fresh air entering through superficial workings.

Systematic sampling was continued both at the fan and the 2,400-ft. level and anemometer and temperature readings were taken regularly at the latter point. Owing to the greater significance of the observations made at the 2,400-ft. level a selection from these data, given in Table I, will be sufficient to show the course of events.

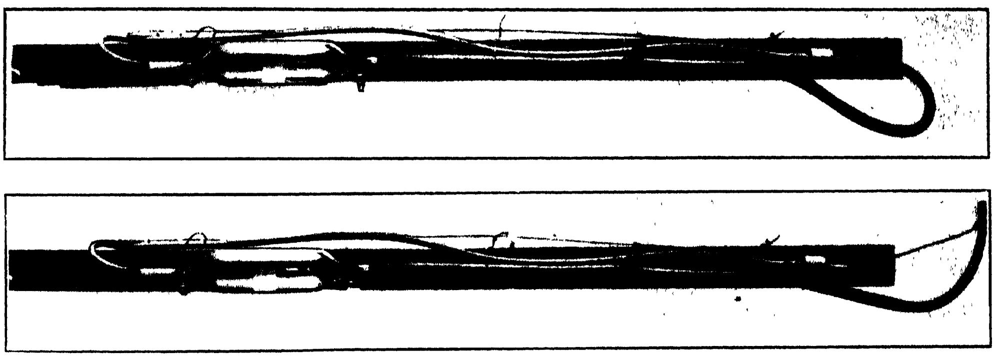


FIG. 1—GAS SAMPLING APPARATUS USED AT ARGONAUT MINE

TABLE I—COMPOSITION OF GASES AT 2,400-FT. LEVEL

				Gas Composition (in Per Cent)			
				By Orsat			By Detector
Date	Time	Temp., Deg. F.	Air Vol., Cu.Ft. Per Min.	C_2	CO_2	CO	CO

*The writer spent 4 weeks at Jackson, Calif., as consulting engineer for the Industrial Accident Commission of California. He desires to acknowledge the assistance rendered by Orr Woodburn, of the Globe Miami District Mine Rescue and First Aid Association, and of various rescue men working under the direction of B. O. Pickard, of the U. S. Bureau of Mines.

[1]"Flue Gas Analysis by Means of the Orsat Apparatus," by Henry Kreisinger and F. K. Ovitz. Bulletin 97, U. S. Bureau of Mines.

[2]So far as the writer knows, this was the first time that the carbon monoxide detector has been used to any extent in connection with a mine fire. Its indications were checked repeatedly by the Orsat apparatus and also confirmed by tests with canary birds. It was found that the color scale of the instrument could be easily read underground in the concentrated beam of two carbide lights or two pocket flash lights. The simplicity of the instrument and the ease with which determinations are made suggest that it might be of use in connection with regular mining operations.

Accurate work with the anemometer was impossible and the variations in the gas volumes shown above are without significance. The gradual decrease in the CO_2 and CO showed that the fire was being slowly smothered owing to the continued effectiveness of the bulkheads. At times large quantities of water mist were present in the gas coming up the Muldoon raise at the 2,400-ft. level. The water mist was doubtless due to one or both of the following causes—namely: the penetration of the fire zone by water or the progress of the fire to a point where considerable water entered the shaft.

The diminution in the carbon monoxide was closely watched from day to day in the hope that the atmosphere in the Muldoon system below the 2,400-ft. level would clear sufficiently so that rescue parties could safely descend to the lower levels of the mine through this entrance. The atmosphere, however remained irrespirable up to the afternoon of Sept. 17, and early in the morning of the 18th, connection was made between the 3,600-ft. level of the Kennedy and the 4,200-ft. level of the Argonaut.

During the time of the exploration work and the removal of the bodies, gas samples were analyzed at frequent intervals, but there was no indication that the air entering the mine through the Kennedy connection caused any change in the fire zone.

Calculating the Extent of the Fire

One of the much-discussed subjects prior to the entrance of the Argonaut shaft through the Kennedy connection was the extent of the fire zone in the shaft and particularly the question as to whether the 4,200-ft. station in the Argonaut shaft would be found intact. On Sept. 4 the writer made a rough calculation of the amount of timber which had been burned up to that time, and at intervals after that this calculation was brought up to date. For the period covered by the gas analyses these calculations were based upon the volume and total carbon content of the gas coming up the Muldoon raise at the 2,400-ft. level. For the initial period of the fire, assumptions were made as to the volume of air entering the fire zone, and the extent to which the oxygen was consumed by the burning timber. According to data furnished by the management, the timber used in the Argonaut shaft corresponded to 1,200 lb. of wood per running foot of shaft. The wood was assumed to contain 50 per cent carbon. A summary of these calculations is given in Table II.

TABLE II ESTIMATE OF SHAFT TIMBERING BURNED

Date	Time Interval in Hrs	Assumed Air Vol Cu Ft Per Min	Basis of Calculation	Wood Consumed Lb. Per Min	Wood Consumed Total Tons	Corresponding Length of Shaft in Ft
8-28	4	30,000	50% oxygen utilized	200	24	40
8-28 to 8-29	20	15,000	50% oxygen utilized	100	60	100
8-30 to 8-31	72	10,000	50% oxygen utilized	67	144	240
9-1 to 9-10	216	4,000	6.5% $CO+CO_2$	17.6	114	190
9-10 to 9-19	216	4,000	5% $CO+CO_2$	12	77.8	130
Total length of shaft timbering entirely consumed						706

The assumptions used in calculating the quantity of timber consumed during the early period of the fire before exact gas data were available were considered to be liberal. The computations based on gas data are fair approximations, but indicate only the quantity of timber totally destroyed. There was no way of knowing whether the timbering in a single continuous section of shaft had been destroyed or whether partial destruction had occurred throughout a greater length of shaft. Balancing these several considerations, the writer expressed the opinion that not more than a thousand feet of shaft timbering had been involved and that consequently the 4,200-ft. station would be found intact. Subsequent explorations have shown that the shaft was not burned below the 3,700-ft. level, and it seems likely that the estimate will prove to be approximately correct.

The Value of Gas Analyses

As the events at the Argonaut were followed from day to day one was repeatedly impressed with the fact that the analyses and other observations of the gas stream coming up the return airway furnished the only means of judging what was going on in the fire zone. These observations not only showed that the fire had been placed under control by the bulkheads but also that it was being slowly extinguished. In this case the story told by the gas work is a relatively simple one. During the previous fire at the Argonaut in 1919 a somewhat similar program of gas sampling was carried out and on several occasions variations in the gas composition gave notice of occurrences underground which required immediate attention.

It is possible that the utility of the systematic determination of gas composition, gas volume, etc., in connection with mining operations has not been fully appreciated. Seepages of methane occur in certain formations and there are several cases on record where explosive mixtures of this gas with air have been formed in underground workings in California. Warning of such seepages might be obtained by analysis of the return air before dangerous quantities have collected. In a similar way, the influx of air high in carbon dioxide from old workings, due perhaps to movement of the ground or failure of an old bulkhead, might be detected. The underlying consideration is that an examination of the return air may yield information in regard to an occurrence at a remote point, thus giving notice of a condition which requires attention.

The New Chemical Element, Hafnium

In *Chemistry and Industry* for Jan. 26, we read of the discovery by Professors Coster and Hevesy, of Copenhagen, of a new element, called hafnium, after Hafniae, an ancient name for Copenhagen. The new element is homologous to zirconium and is apparently present in specimens of zirconium minerals to the extent of about 1 per cent. It has been discovered by means of its X-ray spectrum, and the method will in all probability be applied to advantage in the discovery of other elements.

For some years past the University of Copenhagen has made valuable contributions in the department of both physics and chemistry. The theories of Professor Bohr as to the structure of the atom and the calculations he has made of the orbits of the revolving electrons have gained recognition and have assisted in solving the difficulties of the emission of ordinary bright-line spectra. The output of accurate determination of X-ray spectra by Professors Hjalmar and Coster and others has been considerable, and a complete survey of this interesting field of research is now being undertaken. The Scandinavian men of science seem to abound in genius as do their minerals in elements!

What Happens During Fermentation?

Some Recent Developments Which Have Given Us a Better Insight Into Various Biochemical Processes of Industrial Importance

BY F. F. NORD
Doktor Ingenieur, Berlin

THE fermentation industries stand foremost in importance among the technical consumers of agricultural products. Tremendous quantities of alcohol, lactic acid, butanol, acetic acid and other chemical materials are prepared from carbohydrates with the help of micro-organisms. Although we are intimately acquainted with these final products and with the raw materials from which they are obtained, we have only begun the research which, with the aid of organic chemistry, will penetrate into the real nature of these reactions.

This work has, however, already led to significant and important results. Among the more recent developments I need mention here only the discovery of the pyroracemic acid fermentation and the sugar-free fermentations and the new theory of alcoholic fermentation arising from these discoveries. This work has led to supplementing Gay-Lussac's classic fermentation formula of 1810

$$C_6H_{12}O_6 = 2C_2H_6O + 2CO_2$$

by the two new equations:

$$C_6H_{12}O_6 = CH_3CHO + CO_2 + C_3H_8O_3$$

$$2C_6H_{12}O_6 + H_2O = CH_3COOH + C_2H_5OH + 2C_3H_8O_3 + 2CO_2$$

Expressed otherwise, it may be said that sugar is split up into acetaldehyde, glycerine and carbonic acid as well as transformed into alcohol, acetic acid, glycerine and carbonic acid.

THE INTERMEDIARY STAGE

From fermentation practice we know that one molecule of sugar yields two molecules of ethyl alcohol and two molecules of carbonic acid without so much as the slightest indication of either C_2H_5— or CO_2— groups existing in the sugar. This is a typical example of a reaction which is possible only by passing through intermediary stages. This view is not a novel one. It has obtained for 30 years and yet search for these intermediary stages was unsuccessful until the fermentability of pyroracemic acid was definitely established.

This study is bound up with that of the activity of the enzyme *carboxylase*, contained in the complex *zymase* that splits the sugar into alcohol and carbonic acid.

Pyroracemic acid, which might potentially be present in grape sugar and in other fermentable carbohydrates, is split into acetaldehyde and carbonic acid according to the following simple equation:

$$CH_3COCOOH = CH_3COH + CO_2$$

TABLE I—RELATION OF SODIUM SULPHITE CONTENT TO GLYCERINE YIELD

Proportion of Sodium Sulphite to Sugar (Per Cent)	Yield of Glycerine in Per Cent of Theoretical
40	23.1
67	24.8
80	27.3
100	30.1
120	33
150	34.6
200	36.7

Here then we have bodies in which carboxyl and ethyl remnants are found and how they came into existence is no longer a subject for speculation, but can be demonstrated experimentally. The facility with which pyroracemic acid yields to this characteristic division into acetaldehyde and carbonic acid makes it immaterial biologically whether, in fermentation processes, acetaldehyde and carbonic acid as such are assigned their function, or whether it be in the form of their union as pyroracemic acid.

COMMERCIAL PRODUCTION OF GLYCERINE

Outstanding among the practical achievements in the fermentation field is the commercial production of glycerine in Germany by Connstein and Ludecke. The great dearth of glycerine among the Central Powers (following the cutting off of imports of fats and oils) and the demand for military purposes prompted the theoretical researches which eventually led to this process.

Sugar was available as a raw material and accordingly every effort was concentrated on its fermentation. Previously this had been conducted only in neutral or faintly acid solution. Knowledge of the facile formation of acetaldehyde which has previously been referred to, and the work of Bunte and later of Kerp on sodium acetaldehyde sulphite, suggested the possibility that by successfully removing the acetaldehyde in the form of that compound

$$CH_3CHO + Na_2SO_3 + H_2O = CH_3CHOH.SO_3Na + NaOH$$

some glycerine might be formed provided suitable conditions for the fermentation were maintained. In the first experiments a number of compounds of alkaline reaction were used such as disodium phosphate, sodium carbonate, sodium acetate and sodium bicarbonate. However, these gave rise to the growth of a great many lactic-acid bacteria, which, while flourishing in the alkaline nutrient medium, not only consumed large quantities of sugar but also were the cause of an impurity which was difficult to remove from the resulting glycerine.

The alkaline salts were next replaced by disodium sulphite. This salt, when added to the mash even in very considerable quantities, does not inhibit fermentative action of the yeast and in addition is a valuable antiseptic.

The manner in which the yields of glycerine increase with increasing amounts of this salt may be observed from the figures in Table I.

It is of significance to note that during the war the monthly production of glycerine by this method exceeded 2,000,000 lb. and the yield was 20 to 25 per cent.

THE THEORY EXPLAINED

With such commercial results attained, fresh impetus was given to attempts at the theoretical explanation of the reactions involved. The way was shown by C. Neuberg and E. Reinfurth, who in their very extensive investigations proved that the secondary sulphites enter into a very loose combination with sugar which in aqueous solution undergoes almost complete dissociation. The resulting sulphite complexes with aldehydes are more stable, especially the sulphite-acetaldehyde combination. With any amount of sulphite employed, the quantities of acetaldehyde and glycerine produced are found to be in relation of 1:1 mol. As regards

the participation of the sulphite, the ideal fermentation equation now becomes (where M = alkali metal)

$$C_6H_{12}O_6 + M_2SO_3 + H_2O = CH_3CHOH.OSO_2M + MHCO_3 + C_2H_5O_3$$

The generation of acetaldehyde and glycerine may be said then to be represented by the following reactions:

$$C_6H_{12}O_6 + 2H_2O = C_6H_8O_4 \text{ (methylglyoxal-aldol)}$$
$$C_6H_8O_4 = 2CH_3COHCOH = 2CH_3COCOH \text{ (methylglyoxal)}$$
$$2CH_3COHCOH + 2H_2O = CH_2OHCHOHCH_2OH \text{ (glycerine)} + CH_3COCOOH \text{ (pyroracemic acid)}$$
$$CH_3COCOOH = CO_2 + CH_3COH \text{ (acetaldehyde)}$$
$$CH_3COCOH + CH_3COH + H_2O = CH_3COCOOH + C_2H_5OH$$

In normal alcoholic fermentation the final phase means a reduction of acetaldehyde to ethyl alcohol. By fixing the acetaldyhyde in the form of a sulphite complex ($CH_3CHOHOSO_2M$) it is withdrawn from the final phase of hydrogenation and inasmuch as free hydrogen is not being generated, another reduction product, glycerine, is formed in equivalent amount. The more sulphite present the more acetaldehyde is held and consequently the more glycerine can be produced.

In studying these reactions one is impressed with the strategic position held by the pyroracemic acid and by acetaldehyde. The whole series of equations is based on the assumption that initially two molecules of water are split off to form methylglyoxal—the first product with three atoms of carbon in the molecule. All further rearrangements amount to repeated transformations of methylglyoxal in conformance with the Cannizzaro reaction. In the first, pyroracemic acid is formed, and, taking up water, glycerine.

The pyroracemic acid having been dissociated into carbonic acid and acetaldehyde through the action of the enzyme carboxylase, acetaldehyde is present for the second reaction with methylglyoxal (also an aldehyde). After the single Cannizzaro reaction had been confirmed through a number of observations and the succeeding internal rearrangements established biochemically, it stood to reason that this reaction represented a step in the intermediary processes of alcoholic fermentation.

The question now arose as to whether the mixed transformations between simple aldehydes, such as are set forth in the preceding equations, could actually be effected. The author put the question to experimental proof and obtained an affirmative answer. He succeeded in bringing about this transformation between two aliphatic aldehydes and also between one aromatic and one aliphatic component. This was accomplished by employing a suitable catalyst, and a series of investigations completely confirmed this explanation.

Study of B. Coli Fermentation

With the successful use of disodium sulphite in yeast fermentation, a fresh impetus was given to investigations on the metabolic procedures in the case of other micro-organisms.

Nature offers in the widely occurring *B. coli* an instance of carbohydrate fermentation on a vast scale. This agency is not limited to the sugars proper, but is concerned with related substances as well—for instance, with mannite and glycerine.

It will be recalled that the yeasts are comparatively resistant to the alkaline sulphites, which, as we have seen in the case of glycerine, contribute to the mechanism of the reactions by assuming the rôle of a binding agent. In applying this principle in the case of bacteria, however, conditions were altered, in so far a the sulphite of an alkaline earth, such as calcium su phite (with a neutral reaction), was used instead o the secondary sulphites of sodium or potassium (o alkaline reaction).

Calcium sulphite offers advantages not only becaus of its neutral reaction but also because of the fac that, since it is insoluble in water, osmotic action harm ful to sensitive organisms is avoided. A disadvantage however, lies in diminished concentration of sulphite ion, although this may in a measure be overcome b agitation.

The rôle of acetaldehyde as a transition factor i fermenting dextrose and glycerine by means of *B. co* has been proved where the calcium sulphite modifica tion has been employed.

Here too acetaldehyde is formed (40 to 45 per cen of the corresponding amount of ethyl alcohol) plainl at the expense of the reactions

$$2C_6H_{12}O_6 + H_2O = 2CH_3CHOHCOOH + 2CO_2 + 2H_2 + CH_3COOH + C_2H_5OH$$
$$C_3H_8O_3 = HCOOH + C_2H_5OH$$

which in a normal coli fermentation result in th alcohol.

Similarly, acetaldehyde as an intermediate product i met with in other fermentation reactions such as thos responsible for putrefaction and also in the citric aci and fumaric acid fermentations.

All of the preceding fermentations by yeast or ba teria are of an anaërobic character. It should, there fore, be of interest to study the *modus operandi* in fermentation where atmospheric oxygen takes a par An example is the production of acetic acid, which i closely related to the different sugar fermentations. Thi is not only because many organisms will form acetic aci from carbohydrates, but also because in the aceti oxidation we see the alcohol, after certain organism had produced it from sugar, further transformed b means of another organism. And, too, the sulphit "blocking" of acetaldehyde in order to arrest the suga fermentation in an intermediary stage has also bee accomplished in the case of vinegar. From one-thir to three-fourths of the acetic acid formed by the rea tion could be removed in the form of acetaldehyd These results were obtained from extensive experime tal investigations with wine and vinegar bacteria, e pecially *B. ascendens* and *B. pasteurianum*.

In practical vinegar making traces of acetaldehyd not infrequently are found, especially in those case where by faulty operation there has been an accumul tion of alcohol with an insufficient air supply.

Butyric Acid and Alcohol Fermentation

The formation of acetaldehyde as an intermediate i butyric acid fermentation has been well proved. B using *B. butyricus Fitz* in the presence of disodiu sulphite, 11.8 per cent of the aldehyde has been show to have been formed. The acetaldehyde and its ald when acted upon by this bacillus yield ethyl alcohol an acetic acid instead of butyl alcohol and butyric aci Although the pyroracemic acid is fully utilized for su plying carbon, yet only traces of butyric acid are forme

The aldol of pyroracemic acid, the

α keto-γ-valerolactone-γ-carboxylic acid

$$\begin{array}{l} CH_3\text{—}C(OH)\text{—}COOH \\ \quad | \\ CH_2COCOOH \end{array}$$

(condensation product of two molecules of pyroracem

acid) yield considerable amounts of butyric acid when acted upon by the *B. butyricus Fitz.*

How pyroracemic acid functions as an intermediate product in this complex process is made apparent by the following reactions:

$$C_6H_{12}O_6 = 2CH_3COCOOH + 4H$$
$$2CH_3COCOOH = C_6H_8O_6 \text{ (aldolization)}$$
$$(a)\ C_6H_8O_6 = 2CO_2 + C_4H_8O_2 \text{ (butyric acid)}$$
$$(b)\ C_6H_8O_6 + 4H = 2CO_2 + H_2O + C_4H_{10}O$$
(butyl alcohol)

Thus it will be seen that acetaldehyde occupies a position of great biological importance.

It has been isolated from many different carbohydrate fermentations. There have been vague indications of the presence of aldehydes in physiological processes, but almost without exception evidence has been lacking as to the kind of aldehyde present. In cases where acetaldehyde has been definitely isolated its presence has been explained as a secondary oxidation of ethyl alcohol. It is well known that alcohol will form acetaldehyde under a number of circumstances, such as by contact with porous bodies, by exposure to light and by various metallic surfaces in presence of air. Such qualitative traces as were noted in normal fermentations were explained also as secondary oxidation of alcohol. However, this would not account for such amounts as are indicated in the sulphite fermentation—viz., 75 per cent of the alcohol present.

Volume Changes During Hardening

In the course of the investigations conducted by Howard Scott at the Bureau of Standards for the gage steel committee, an attempt was made to locate the principal source of distortion during hardening. Gage specimens made of a high-nickel steel, containing 0.11 C, 0.89 Mn, 0.19 Si and 31.0 Ni (which has no hardening transformation), were quenched in water from 800 deg. C. and the following changes noted:

	Length	Diameter (In × 10^{-3})		
No	(In × 10^{-3})	Left	Center	Right
I 21	—0 08	-0 16	0 14	-0 14
I 22	—0 11	-0 33	0 43	-0 46

I 21 was silver plated and I 22 unprotected, so it was necessary to pickle the latter specimen, which circumstance probably accounts for the greater decrease in size. The changes are, however, very small, perhaps within the limits of reproducibility, so the effective changes must be associated with the true hardening transformation called by Scott Ar″.

The hardening transformation occurs in tool steels at a temperature below 300 deg. C. and is sometimes not complete at ordinary temperatures. It involves a considerable change in volume of the steel and this suggests that the dimensional changes may be controlled by the rate of cooling through this range. An increase in volume cannot be avoided if high hardness is desired, so the problem of dimensional changes resolves itself into the problem of producing uniform dimensional changes in all directions. Two obvious courses are open for accomplishing this; either to use a deep hardening steel and cool slowly through the hardening transformation, thereby permitting it to progress uniformly through the whole mass, or to harden only the surface layers of the steel. The latter expedient introduces a variable which is very difficult to control.

A chromium-bearing steel containing 1.00 per cent carbon and 1.34 per cent chromium is much used for gages, and experiments were made as outlined in the following table:

Quenching Temperature, Deg C	Nature of Bath	Temperature of Bath, Deg. C.	Change in Length In. × 10^{-3}
825	Oil	130 to 90*	2 05
840	Oil	23	4.48
840	Liquid Air		6 22
830	Oil	140	5.47
840	Oil	140	8 27
800	Water	23	15 65

*Taking 2 hours

To reveal distortion, the change in length is calculated from the change in specific volume, giving the total length change for uniform change in all directions. Differences between these values and the values for length change are then a measure of distortion. The distortion for water quenching is very marked, the actual length change being more than twice the computed change. There is, however, little distortion on oil hardening, though cooling rapidly from the oil quenching bath at 140 deg. C. appears to cause greater distortion than cooling slowly from that temperature.

The conclusion should not be drawn, because the oil-quenched specimens show less distortion than the water-quenched specimens on hardening, that they will necessarily show less dimensional change with time. In fact, from the indications so far, the opposite appears to be true—i.e., that the water-quenched specimens change less with time.

The volume change is about 0 5 per cent for water quenching and probably represents the maximum for full hardening. Certain of the oil-quenched specimens show as great a volume change as this, but it is doubtful whether the hardening has penetrated to the center. 1¼-in. diameter specimens of this chromium steel quenched in oil from 1,000 deg. C. show only a surface layer of martensite, but penetration to the center on water quenching.

Oil quenching evidently produces little distortion, but that it gives maximum hardness is open to question. None of the specimens listed in the table showed full file hardness, while those quenched in oil from 800 deg. C. were distinctly soft and probably not martensitic even on the surface.

Fertilizer Industry Consumes the Largest Quantity of Sulphuric Acid

Eliminating the amount of sulphuric acid used for munitions and allowing about 200,000 tons for peacetime explosives, an indicated requirement of 5,010,000 tons for normal peace industries is arrived at. The normal amount of sulphuric acid used for explosives would thus be less than the quantity used in the metallurgical industry, including the manufacture of storage batteries, but more than the quantity used for paints, lithopone and glue. Fertilizers head the list as taking the largest quantity. However, the need for so much acid in the summer of 1918 operated to reduce the amounts used for other purposes, for pre-war consumption in the manufacture of phosphate fertilizer was about 2,300,000 tons a year and it has since grown to more than 2,500,000 tons, or over half the total. Moreover, it is to be noted that ammonium sulphate, and probably other products classified with "chemicals, drugs and ammonium sulphate," are themselves used for fertilizers or to make fertilizers, so that without doubt the fertilizer industry is normally by far the greatest user of sulphuric acid.

Structure of Chromium-Nickel Steel

BY H. B. PULSIFER AND O. V. GREENE
Assistant Professor Metallurgy, Lehigh University, and Metallurgist, Philadelphia & Reading R R Co

A Series of Micrographs Fail to Show Any Change in Structure in Quenched Cr:Ni Steel After Various Draws, Despite Large Differences in Physical Properties — Precautions Needed in Etching and Photographing

WE had available a series of 1-in. round bars manufactured in the basic open-hearth by the Bethlehem Steel Co., of the following analysis:

	Chromium-Nickel S.A.E. 3240	Chromium-Molybdenum
Carbon	0.38	0.46
Manganese	0.52	0.72
Phosphorus	0.018	0.028
Sulphur	0.031	0.031
Silicon	0.20	0.23
Chromium	1.08	1.07
Nickel	1.87	.....
Molybdenum		0.35

Physical properties after a variety of heat-treatments had been studied in a graduation thesis by former students, and found to be very similar to those given for similar material by H. J. French in *Metallurgical & Chemical Engineering* of Oct. 15, 1917, and in the Society of Automotive Engineers' Handbook. The chromium-molybdenum material is distinctly superior to the chromium-nickel.

Both steels were normalized by heating to 1,600 deg. F. during 16 hours, soaking 8 hours, and slow cooling. Preliminary fracture tests of quenched pieces heated to every 50 deg. interval from 1,400 to 1,600 deg. F. indicated 1,500 deg. as giving the finest grain and the smoothest fracture.

The test pieces were cut in 5-in. lengths; eight specimens were quenched in oil and eight were quenched in water after holding at 1,500 deg. F. for an hour. The pieces of each series were then drawn at 100 deg. intervals from 600 to 1,300 deg. F.

Preliminary examination at 100 diameters for structure was made after the usual brief etching with stock picric acid solution. These showed a martensitic structure with the grain boundaries imperfectly disclosed. (Fig. 6.) Archer's method[1]—etching in freshly prepared 4 per cent picric acid in ethyl alcohol for several minutes, and then rubbing off the carbonaceous smudge on moist broadcloth—was then used by Mr. Greene and each specimen was photographed at a thousand diameters magnification. The conspicuous development of the cellular structure requires several minutes immersion in the picric acid solution and either a too brief or a too long period fails to give the network clearly. The cellular texture is always present in the chromium-nickel series; we find in chromium-molybdenum steels it is more difficult to get the network sharply and it is also obscured by an apparent change of the martensitic stock to troostite about the grain boundaries.

The microscopic structure of the chromium-nickel samples appears to be a uniform cellular martensite; this means that the martensite obtained by the quenching has not been changed microscopically by the tempering operation. It is well known that the tempering operation alters the physical properties enormously and the tempered specimens etch more easily as the temperature of the drawing is increased, but in this chromium-nickel series the microscopic appearance at 1,000 diameters magnification is not changed. There is no evidence that the cellular nature, or the grain structure, has been affected in the slightest. Fig. 1 is a typical print. We fail to find any noticeable difference in the ground-mass, the size of the grains or the width of the grain boundaries as the drawing temperature

[1]Archer, *Trans.*, A.I.M.E., vol. 62, p. 754 (1920).

FIG 1—Cr-Ni, OIL QUENCHED AND DRAWN TO 1,200 DEG. F.
1,000 dia. 12 min. etch. Leitz microscope. Cellular martensite.

FIG. 2—Cr-Mo, WATER QUENCHED AND DRAWN TO 1,300 DEG. F.
1,000 dia. 5 min. etch. Pellin-Zeiss microscope. Shows dark troostite appearing in spots.

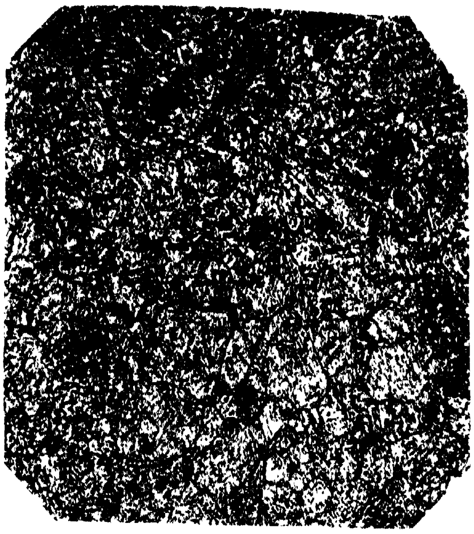

FIG. 3—Cr-Ni, WATER QUENCHED AND DRAWN TO 1,000 DEG. F.

250 dia. 15 min. etch. Pellin-Zeiss microscope. Cellular martensite.

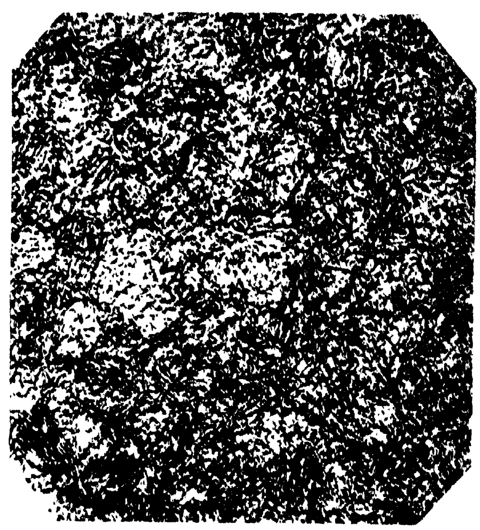

FIG. 4—Cr-Ni, OIL QUENCHED AND DRAWN TO 1,100 DEG. F.

500 dia. 11 min. etch. Pellin-Zeiss microscope. Cellular martensite.

has been raised. Since the physical and chemical properties have changed very greatly, we must infer that the atomic readjustments caused by the heating are submicroscopic.

We doubt if there is any component which could be called troostite in this series, even at draws as high as 1,300 deg. F. Thus Seidell and Horvitz[4] give a print of a very similar structure and call the ground-mass martensite "surrounded by troostite envelopes." If the grains were bounded by troostite, or if troostite began to form at the lower drawing temperature, the amount of that component should increase with the temperature of drawing.

In the chromium-molybdenum steel there is much more evidence of the formation of troostite. The two specimens drawn at 1,300 deg. F. after quenching in oil and water respectively show considerable amounts of a second component (Fig. 2). This second component etches out dark in the picric acid solution, its granules are extremely fine and it likely corresponds to the troostite of the simple carbon series.

Prolonged efforts were made to develop the cellular structure of the chromium-molybdenum stock as completely as was done with the chromium-nickel material. Although traces of units were always apparent and individual grains could easily be known from the arrangement of the striations, no particular success was obtained. Fig. 2 is characteristic of the general results in this respect. Possibly the suppression of the definite grain outlines of each particle has its physical expression in the enhanced strength of the steel[5].

Fig. 3 is a 250-diameter print from the water quench chromium-nickel bar drawn to 1,000 deg. F. This bar had a very perfect cellular texture, so that pictures were more easily obtained than from any other specimen.

[4]Seidell and Horvitz, "Physical Qualities of High-Chrome Steel." *Iron Age*, Jan 30, 1919.

[5]Elastic limit and ultimate strength for the quenched Cr:Ni steel, tempered at 1,300 deg. F., are 70,000 and 110,000 lb. per sq in., but 80,000 and 120,000 for the Cr:Mo steel.

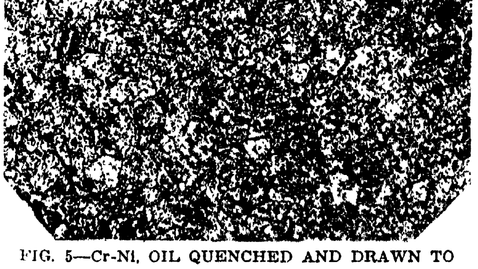

FIG. 5—Cr-Ni, OIL QUENCHED AND DRAWN TO 1,300 DEG. F.

100 dia. 8 min. etch. Pellin-Zeiss microscope. Cellular martensite.

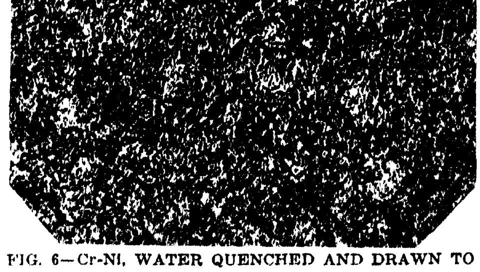

FIG. 6—Cr-Ni, WATER QUENCHED AND DRAWN TO 1,100 DEG. F.

Short etch with stock solution. 100 dia. Pellin-Zeiss microscope. Martensite grains imperfectly disclosed.

Fig. 4 is a 500-diameter print from the oil quench drawn to 1,100 deg. F. The grains appear less sharply defined, while there is slight evidence of any alteration of the martensite.

Fig. 5 is from a series of chromium-nickel specimens drawn to 900, 1,100, 1,200 and 1,300 deg. respectively. The fine-grained nature of all the stock is apparent from this print at 100 diameters; although the grain boundaries are sharp and distinct, it must be remembered that either a shorter or longer time in the etching than the optimum would leave the grains very indistinct. As evidence of how uniform the martensite is in the chromium-nickel series and to show the results of a brief picric acid etch we give Fig. 6 from the preliminary work. A casual inspection reveals that separate grains are present in the picture, but it is equally obvious that for sharpness or clean-cut delineation such etching cannot compare with that given in Figs. 1 to 5.

A final word may be offered as to pitting and tarnishing of the specimens during the etching, drying and photographing. The material is very prone to become pitted; round pit marks are only too conspicuous in Fig. 5. Only sharp and prompt work will keep them subordinated; it may often be necessary to repeat the final polishing and etching. Tarnishing is even more serious and difficult to overcome than the pitting. If any of the specimens stand exposed in the open air or even in a dessicator alteration of the surface begins quickly and spreads rapidly along the grain borders. The corrosion caused by exposure to air resembles a change to troostite; on this account all the specimens were photographed immediately after the polishing and etching. Specimens were resurfaced in case a photograph had to be repeated the next day.

It might be proposed that the extent of the tarnish might be used as an indication of a change from martensite to troostite, we do not doubt that the changes produced by the tempering have strongly altered some deep-seated forces in the chromium-nickel steel, and even the microscopic structure of the chromium-molybdenum steel, but it would be impossible to admit that a progressive tarnishing could define a structural constituent.

Patents and the Problem of Priority

An interesting aspect of the question of priority, reported in the Feb. 1 issue of *India Rubber World*, presented itself in the suit of the Dovan Chemical Co., Inc., plaintiff, against the National Aniline & Chemical Co., defendant. Judge Manton, in the United States District Court for the Southern District of New York, rendered decision in favor of the plaintiff, proclaiming that earlier and inadequate experiments should not be permitted to deprive the successful inventor of his due and just reward. The patent under discussion (No. 1,411,231) was applied for Nov. 12, 1921, and was granted March 28, 1922. It represents a method of improving rubber compounds so that the finished product shall be of superior quality and the time required for vulcanization be greatly lessened. The inventor of this process, Morris L. Weiss, has discovered that diphenyl guanidine not only hastens the vulcanization but results in a final product greatly improved in texture, durability and aging qualities to a much greater extent than when triphenyl guanidine is used.

The use of diphenyl guanidine results in greater elasticity and freedom from bloom. Moreover, it is also very valuable where it is desired to produce a harder or less elastic portion in an article, leaving other parts more elastic and flexible, as in the case of automobile tires.

The defendant, however, urged that others prior to Weiss have tested diphenyl guanidine as an accelerator. At a meeting of the Chemical Society of Philadelphia, in September, 1919, George D. Kratz read a paper in which diphenyl guanidine was referred to as an accelerator. It cannot be claimed, however, that a mere reading of the paper before this society constitutes a statutory publication. Later, in 1920, there appeared in the *Journal of Industrial and Engineering Chemistry* a complete publication by Kratz and others. Although this was previous to the filing of an application by Weiss, it has been shown that the Weiss tests recorded in the spring of 1918 were previous to the reading of the Kratz paper. A careful examination of these tests proves that Weiss was the first to make adequate experiments and to solve the problem of producing diphenyl guanidine in commercial form. Kratz, on the other hand, claims to have made laboratory tests and later to have mixed 30 grams of diphenyl guanidine with rubber stock made into tubes for automobiles. These tubes were sold as imperfect rubber. The amount of acceleration used, however, could have had no substantial effect in the curing of the rubber, as compared with that used in the plaintiff's process, and an invention, to be patentable, should be complete and capable of producing new and useful results.

Utilizing the Waste of Grape Fruit Factories

There is a possibility of the practical and profitable commercial utilization of the stems and pomace from the grape juice factories which are thrown away. The average quantity of grapes crushed for beverage purposes in the 5 years from 1914 to 1918 was 22,000 tons. In this period an average of 660 tons of stems and 4,400 tons of wet pomace was discarded. From this quantity of waste it is claimed that, where the stems yield 2 per cent of cream of tartar, it is possible to secure 13.2 tons of this material.

After the seeds are separated the pomace can be made into a good grade of jelly by a simple process. Experts have calculated that 3,300 tons of wet skins would be available annually from the wet pomace, and it is estimated that this amount of waste would produce 19,800,000 8-oz. glasses of jelly. From this operation about 1,435 tons of dry residue would result which is of value as stock feed.

The grape seeds, comprising 5 per cent of the total weight of fresh grapes, or about 1,100 tons, can, after hulling and grinding, be manufactured into oil by two different methods known commercially as the pressure method and the solvent extraction method. The total oil content of the seeds is estimated at 13 per cent, not all of which can be successfully recovered. It is estimated that by means of the pressure method about 89.3 tons of oil and 526.7 tons of oil cake can be obtained. The 484 tons of hulls made available by this process is calculated to yield 48.4 tons of tannin extract. The solvent extraction method yields about 132 tons of oil with 968 tons of meal possessing a lower market value than the press cake from the pressure method. Refining, bleaching and deodorizing of the oil produce a palatable condimental oil with properties similar to those of the soy bean and cottonseed oil.

Pyruvic Acid From Lactic Acid

Significance of This Problem in Electrolytic Oxidization Is Discussed and Elucidated

BY J. G. SMULL AND P. SUBKOW
W. H. Chandler Chemical Laboratory, Lehigh University

THE oxidation of lactic acid by purely chemical methods, not electrolytic, can be controlled so as to yield pyruvic acid, as represented by the equation

$$CH_3CH(OH)COOH + O = CH_3COCOOH + H_2O$$

This can be accomplished either with[1] $KMnO_4$ or with H_2O_2, using $Fe_2(SO_4)_3$ as an oxygen carrier. The pyruvic acid may be further oxidized by H_2O_2 with or without a catalyst,[2] with the formation of acetaldehyde and carbonic acid. The oxidation of lactic acid by electrolytic means has been shown to proceed in the following stages:[3]

$$2CH_3CH(OH)COO^- + 2(+) = CH_3CHO + CO_2 + CH_3CH(OH)COOH$$

$$CH_3CH(OH)COOH + O = CH_3CHO + CO_2 + H_2O$$

Rockwell[4] has found that in the electrolytic oxidation of pyruvic acid, acetaldehyde and CO_2 are the final products of the reaction.

It was decided to investigate more thoroughly the electrolytic oxidation of lactic acid to see whether its transformation to pyruvic acid could be accomplished. Ordinary electrolytic oxidation of lactic acid proceeds mainly with the formation of acetaldehyde, formic and acetic acids, together with a large amount of CO_2. The authors found that in acid solutions the aldehyde is oxidized to acetic acid, and in alkaline solutions to formic acid, corroborating the work of Heimrod and Leven.[5] In both acid and alkaline solutions a large amount of CO_2 is liberated. It was found in our experiments that if certain precautions were taken to remove any pyruvic acid formed from the sphere of oxidation, the latter acid can be prepared electrolytically.

The cell employed in these tests was composed of anode and cathode compartments separated by a semi-permeable diaphragm, consisting of an ordinary porous cup. Arrangements were made for cooling and for stirring the anode portion. In all but the last experiment the electrodes were of platinum. In the last experiment a perforated lead sheet was used as the anode and an iron gauze as the cathode. The anolyte was stirred vigorously in order that the electrolyte at the anode be not impoverished during the oxidation.

OXIDATION IN ACID SOLUTION

Anolyte—75 cc. consisting of 27 per cent lactic acid; 20 per cent sulphuric acid; platinum anode, 75 sq.cm.; anode current density, 0.04 amp. per sq.cm.

Catholyte—20 per cent sulphuric acid; platinum wire cathode.

The current was passed until theoretically one-half of the lactic acid should have been oxidized to pyruvic acid. The object was to keep the former in excess so as to favor its oxidation in preference to that of the reaction products. The depolarization was extremely poor and the current density had to be reduced to 0.0133 amp. per sq.cm. The oxidation proceeds with the formation of acetic acid and CO_2. No pyruvic acid was detected.

OXIDATION IN NEUTRAL SOLUTION

It was thought that if some soluble salt of lactic acid were used, insoluble when converted into the corresponding pyruvic acid salt, it might be possible to remove any pyruvic acid formed from the sphere of oxidation. Copper lactate is soluble six parts in one hundred parts of water. The copper pyruvate is insoluble. Otherwise it was believed that because of the vigor of the oxidation any pyruvic acid formed was burned to CO_2. The copper lactate was obtained by treating lactic acid with an excess of basic copper carbonate and filtering off the residue.

Anolyte—350 cc. of copper lactate, 6 parts in 100 cc.; enough $Cu(NO_3)_2$ was added to raise the copper concentration to 20 per cent; platinum anode, 150 sq.cm.; anode current density 0.04 amp. per sq.cm.; complete depolarization.

Catholyte—The catholyte contained 20 per cent copper as copper nitrate; platinum wire cathode.

The current was run long enough to oxidize theoretically one-half of the lactic acid to pyruvic acid. The copper concentration in the anolyte was kept high so that the copper lactate was not impoverished, in copper, during electrolysis. The oxidation products were acetaldehyde, acetic acid, formic acid and CO_2. An insoluble precipitate was obtained. This was filtered off, washed with water and dissolved in ammonia. The solution was made acid with acetic acid and phenylhydrazine added. The characteristic precipitate of the phenyl-hydrazine of pyruvic acid was obtained. Due to the slight solubility of copper lactate, the current efficiency was low. The oxidation of the lactic acid to CO_2 by the strong evolution of oxygen accounts for the complete depolarization noted.

OXIDATION IN ALKALINE SOLUTION

1. With insoluble anode:

Anolyte—125 cc. of 40 per cent sodium lactate solution containing 6 grams sodium hydroxide; platinum anode, 150 sq.cm.; anode current density 0.0133 amp. per sq.cm.; complete depolarization.

Catholyte—A 6 per cent solution of sodium hydroxide.

The current was passed long enough to oxidize theoretically one-half of the lactic acid to pyruvic acid. The concentration of sodium hydroxide in the anolyte was constantly diminished, due to electrolysis and to neutralization by the CO_2 liberated in the oxidation. The hydroxide concentration in the anolyte was maintained during the process by addition of caustic soda solution from time to time. The depolarization was complete. The oxidation proceeds, mainly, with the formation of acetaldehyde, formic acid and CO_2. No pyruvic acid was detected.

2. With attackable anode:

The use of platinum anodes which have a high oxygen overpotential insures an extremely vigorous oxidation. It was thought that a more mild oxidation might result in a greater yield of pyruvic acid. Lead is at the other end of the electromotive series from platinum with respect to its oxygen overpotential. For the same current density, the lead would give a very much milder

NOTE: The authors wish to acknowledge their indebtedness to the Callender-Carnell Fellowship in Chemistry which made this investigation possible.

oxidation.[6] The lead is oxidized to PbO, which is dissolved by sodium hydroxide. This oxidation would further reduce the oxygen concentration at the anode and thus reduce the vigor of oxidation. Lead is made more useful, since, though lead pyruvate is soluble in water, it was found that it is converted on standing into a basic salt, insoluble in water or acetic acid. This hydrolysis would be facilitated by an alkali, and thus insure the removal of the pyruvic acid from the zone of oxidation.

Anolyte—27 per cent sodium lactate solution made alkaline with sodium hydroxide; perforated lead anode; anode current density 0.0074 amp. per sq.cm.

Catholyte—A 6 per cent sodium hydroxide solution; iron wire gauze cathode.

The depolarization in this experiment was complete. The current was passed until the lead was entirely corroded. This happened when only one-quarter of the lactic acid could have been theoretically oxidized. The lead was converted into $PbCO_3$ which analyzed 74.3 per cent Pb. The current efficiency of corrosion was about 95 per cent.

The lead carbonate was washed clean, decomposed with acetic acid and the insoluble residue treated with strong caustic soda in which it was soluble. The solution was made acid with acetic acid and gave the test for pyruvic acid with phenyl-hydrazine.

The anolyte after filtering contained no acetaldehyde. On extraction with ether no acetaldehyde ammonia could be detected when NH_3 was passed through the cooled ether solution. Upon evaporation of the ether a reddish resin of the type formed by the polymerization of acetaldehyde in alkaline solution was obtained. Acetic and formic acids were found. The anolyte no doubt contained some pyruvic acid due to the solution of some of the basic lead pyruvate in the alkali. An attempt to remove the pyruvic acid by acidification with acetic acid and steam distillation gave uncertain results, with the phenyl-hydrazine test.

Importance of Process

It has been shown[7] that the simultaneous electrolysis of the alkali salts of pyruvic acid and other fatty acids yields higher ketones, in satisfactory amounts. The technical importance of the higher ketones as organic solvents has long been appreciated. However, the commercial significance of the above electrolysis depends on a cheap source of pyruvic acid.

Another use for pyruvic acid is found in the synthesis of "atophan," or as it is sometimes called, "cincophan," one of the most important remedies for rheumatism. "Atophan" is a condensation product of pyruvic acid, benzaldehyde and aniline. The cost of pyruvic acid, made by the present method of the dry distillation of tartaric acid, is one of the large items in the cost of this pharmaceutical.

The above considerations make a source of relatively cheap pyruvic acid of prime importance. The present supply of lactic acid, at a low cost, increases its interest as an intermediate in the preparation of pyruvic acid. With this view in mind, this investigation was begun. The results included in this paper are given only as preliminary, indicating that pyruvic acid can be obtained by an electrolytic oxidation of lactic acid, the yields being dependent upon careful control.

Summary

1. The electrolytic oxidation of lactic acid in acid, neutral and alkaline solutions has been studied. In the latter case both soluble and insoluble anodes were used.

2. It was found that if care is taken to remove any pyruvic acid formed from the sphere of oxidation as an insoluble salt or if care is taken that the oxidation is kept mild, or, better, if both conditions are combined, pyruvic acid is obtained.

Properties and Tests of Tar Creosotes

Creosote is widely used as a preservative because of its chemical, physical and toxic properties. The literature on it, however, is widely distributed in technical periodicals, society proceedings and government reports. It is very fortunate, therefore, to have available a comprehensive résumé of the information in all this literature in the publication of the U. S. Department of Agriculture Bulletin 1036, entitled "Coal-Tar and Water-Gas Tar Creosotes: Their Properties and Methods of Testing," by Ernest Bateman, chemist of the Forest Products Laboratory.

This bulletin not only gives a most comprehensive, well-organized review of previous work, but also includes the first publication of the results of research which have been carried out for the purpose of obtaining a broader knowledge of the variations of creosote with different processes of manufacture.

The bulletin is divided into four parts. Part I includes the introduction, a description of tars, and an account of the manufacture of creosote. Part II is a presentation for the first time of the results of research by the author and his co-workers in the Forest Products Laboratory. Part III gives a summary of the chemical, physical and toxic properties of creosotes as a whole. Part IV is concerned entirely with methods of testing and specifications.

Copies of the bulletin can be obtained from the Government Printing Office, Washington, at 20 cents each.

Molding Sands

An investigation on molding sands, its reclamation and re-use, has been under way for some time under the active co-operation of a number of members of the American Foundrymen's Association. Standardization of tests for determining size, shape, cohesiveness, permeability, water content, thermal properties and analyses (including rational, chemical, mineralogical) are still under way and some of them are completed. The Ohio Brass Co. is making investigations for the use of clay in retaining bond strength in molding sand heaps. The Sivyer Steel Casting Co. of Milwaukee, is studying the effect of clay additions on the grain size of sand heaps. The American Steel Foundries Co. has reported on the method and equipment designed, which permits a recovery of about 70 per cent of refuse sand used in steel foundry work. Cost figures show that reclaimed sand costs about $1 per ton, against new sand at the plant at $2.65 to $3.85 a ton. The process involves cleaning the sand grains of adhering fused material, then separating by air currents the good sand from the bad material.

Fundamentals of Rectification

Methods of Operating Which Affect Limiting Composition of Binary Liquids

For Example, the Introduction of Liquid or Gaseous Compounds at Intermediate Levels

BY C. C. VAN NUYS
Chief Physicist, Air Reduction Co., New York City

UP TO this point in our discussion we have not considered the ways and means available for producing either the liquids descending or the vapors ascending in the column.

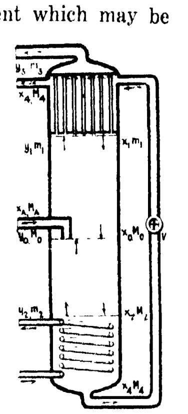
In the actual operation of a rectification system, particularly when we are dealing with a gaseous mixture which must be liquefied at a temperature much below atmospheric, it is of very great importance that the liquefaction be accomplished as far as possible by permitting the heat necessary to be abstracted to flow into the liquids to be evaporated.

One common method of providing both the liquid descending and the vapor ascending in the column is that of admitting the mixture, either liquid or gaseous, at an intermediate level and condensing directly in the upper regions thereof a portion of the ascending vapors and vaporizing directly in the lower regions thereof a portion of the descending liquid.

We shall later on show how this condensation and evaporation must be distributed along the length of the column in order to cause the relation between x and y at all levels to be that for phase equilibrium. Actually to accomplish this result exactly is always impracticable, however, on account of the impossibility of distributing in the required manner in the column the various coils required to furnish or abstract the heat necessary at the various levels. For this reason it is usual to concentrate the vaporizing or condensing effect in certain limited regions in the column by the use of condensers and vaporizers therein.

The arrangement and location of these parts of the apparatus is always a matter of the greatest importance, inasmuch as some possible arrangements may impose severe restrictions upon the compositions possible to be attained in the separated products.

An example of such an arrangement which may be considered with profit in the present connection, where liquid is supposed to be admitted at an intermediate point in the column, is the one illustrated.



In this case, we have a liquid of mass M_A, composition x_A, entering a rectification column at the top of which is a condenser formed of parallel vertical tubes through which the ascending vapor passes, being partly liquefied therein. This liquefaction is accomplished by surrounding said tubes with a liquid M_4 of composition x_4, constituted by the liquid leaving the vaporizer of the column after the pressure thereof has been lowered sufficiently in valve V to cause that condensation. The vapor ascending in the column is produced by evaporating at the bottom thereof a portion of the descending liquid M_2 by means of a coil therein. As before, x_0 is the composition of the liquid M_0, descending in the column at the level of admission of M_A, and we assume, furthermore, that the composition y_0 of the vapor m_0 ascending at this level is that for phase equilibrium with the liquid of composition x_0, if $x_0 > x_A$, or with those liquids combined if $x_0 < x_A$. As before, M_1 represents the liquid entering the top of the rectification column proper, in this case delivered by the tubes of the condenser, while m_1 represents the vapor of composition y_1 entering the tubes of said condenser.

Let m_3 be the mass of uncondensed vapor residue leaving the top of the condenser and y_3 its composition. Then with the arrangement shown in the figure, eleven equations may be written, all homogeneous in the nine (M, m)'s. Ten of these equations are as follows:

$$m_1 = m_3 + M_1$$
$$y_1m_1 = y_3m_3 + x_1M_1$$
$$m_0 + M_1 = m_1 + M_0$$
$$y_0m_0 + x_1M_1 = y_1m_1 + x_0m_0$$
$$J_0m_0 + I_1M_1 = J_1m_1 + I_0M_0$$
$$m_2 + M_A + M_0 = m_0 + M_2$$
$$y_2m_2 + x_AM_A + x_0M_0 = y_0m_0 + x_2M_2$$
$$J_2m_2 + I_AM_A + I_0M_0 = J_0m_0 + I_2M_2$$
$$M_2 = m_2 + M_4$$
$$x_2M_2 = y_2m_2 + x_4M_4$$

These ten equations hold independently of the method employed to accomplish the condensation in the tubes of the condenser and are true even were that condensation produced by the employment of an extraneous liquid surrounding the tubes of the condenser. If the liquid M_1 is produced in the condenser by thermal contact of the ascending vapors therein with the evaporating liquid M_4 as shown in the figure, an additional equation may be written which states that the heat abstracted from M_1 during condensation thereof equals the heat added to M_4 during the evaporation thereof after its pressure has been lowered in valve V.

The heat required to evaporate the liquid M_4 before the pressure thereof has been lowered in the valve V is L_4M_4, where L_4 is the latent heat at constant pressure of the liquid M_4 at the pressure in the rectification column proper. The result of this evaporation would be the fluid M_4 in a condition of saturated vapor at the pressure P_1 before passing through valve V. If this saturated vapor were then throttled in valve V, and if after throttling it were neither superheated nor partly liquefied—i.e., still saturated—it would be in the condition in which it is in the actual case as it leaves the condenser after being evaporated therein.

In that case, if L_1 denotes the latent heat at constant pressure of the liquid M_1 at the pressure P_1, our eleventh equation would be:

$$L_1M_1 = L_4M_4$$

since the total heat of M_4 remains constant during its passage through valve V.

If, however the saturated vapor M_4 at the pressure P_1

*The first three articles in this series were published in the issues of Jan. 31 and Feb. 7 and 14, 1923.

should be partly liquefied when its pressure is released to that prevailing around the tubes of the condenser, then the heat required to evaporate M_1 in the condenser is greater than L_1M_4, the latter being that required to evaporate the liquid M_4 at the higher pressure P_1, and our eleventh equation would be:

$$L_1M_1 = (L_4 + \Delta)M_1$$

where Δ is a quantity depending upon the change of the latent heat of the liquid M_1 when its pressure is *decreased under conditions of constant "total" heat. We shall therefore take our eleventh equation to be:*

$$M_1 = KM_4$$

where, with the arrangement shown in the figure,

$$K = \frac{L_1 + \Delta}{L_1}$$

If, however, the condensation of the liquid M_1 in the condenser be accomplished independently of the liquid M_4, K may be regarded as a quantity whose value is determined by the amount of that condensation.

Now, since we have eleven homogeneous equations among nine (M, m)'s, we may by elimination of all (M, m)'s obtain three independent equations not containing any (M, m).

These three equations are as follows:

$$J_1\frac{x_1 - y_3}{x_1 - y_1} - I_1\frac{y_1 - y_3}{x_1 - y_1} = J_0\frac{x_0 - y_3}{x_0 - y_0} - I_0\frac{y_0 - y_3}{x_0 - y_0}$$

$$\frac{y_1 - y_3}{x_1 - y_1} + K\frac{x_1 - y_1}{x_4 - x_1}$$

$$J_1 - I_1 + (J_1 - I_1)\frac{x_1 - y_1}{y_1 - y_3} = \frac{1}{K}$$

$$(J_2 - I_2)\frac{x_4 - x_2}{x_2 - y_2} + I_1 - I_2$$

We note that the first one of these relations must be satisfied independently of the value of K—that is to say, independently of the method employed to produce the condensation in the condenser.

This being true, we may assume that the mass of liquid M_1 produced in the condenser is the minimum possible amount for a given mass M_1, or what is the same thing, that the mass M_1 is the greatest possible for a given M_1. We have shown above that under these conditions, if we are dealing with a mixture having the property of proportionality latent heats, $x_1 = x_0$, and also that x_0 and y_0, and also x_1 and y_1, are compositions of liquid and vapor in phase equilibrium. In the particular case where $y_3 = 0$, the first of our three independent relations takes the form:

$$\frac{J_1x_1 - I_1y_1}{x_1 - y_1} = \frac{J_0x_0 - I_0y_0}{x_0 - y_0}$$

That is to say, if the points (x_1, y_1) and (x_0, y_0) on the x, y curve are not coincident, the function

$$\frac{Jx - Iy}{x - y}$$

must have the same value at the two points. For a mixture whose latent heat at constant pressure follows the proportionality relation as defined, the two points (x_1, y_1) and (x_0, y_0) necessarily coincide, whatever be the value of y_3. In that case, the first relation becomes:

$$L_1\frac{y_1 - y_3}{x_1 - y_1} = L_0\frac{y_0 - y_3}{x_0 - y_0}$$

where

$$L_1 = L_Bx_1 + L_A(1 - x_1)$$

and

$$L_0 = L_Bx_0 + L_A(1 - x_0)$$

But under these conditions,

$$\frac{y_0}{1 - y_0} = a\frac{x_0}{1 - x_0}$$

and

$$\frac{y_1}{1 - y_1} = a\frac{x_1}{1 - x_1}$$

Eliminating y_1 and y_0, the first relation becomes

$$(x_0 - x_1)[L_Bax_0x_1(1 - y_3) + L_A(1 - x_0)(1 - x_1)y_3] = 0$$

which in general can be true only if $x_0 = x_1$.

This result shows that in general the section of the column between the lower end of the condenser and the level of inlet of M_4 is inoperative and therefore the same result would be obtained if the liquid M_4 be admitted just below the condenser.

With the notation indicated in the figure below our system of equations then becomes:

$$m_1 = M_1 + m_3$$

$$y_1m_1 = x_1M_1 + y_3m_3$$

$$M_4 + M_1 + m_2 = M_2 + m_1$$

$$x_4M_4 + x_1M_1 + y_2m_2 = x_2M_2 + y_1m_1$$

$$I_4M_4 + I_1M_1 + J_2m_2 = I_2M_2 + J_1m_1$$

$$M_2 = m_2 + M_4$$

$$x_2M_2 = y_2m_2 + x_4M_4$$

$$M_1 = KM_4$$

This system of eight equations is homogeneous in the seven (M, m)'s and by elimination of all (M, m)'s, two independent equations may be obtained between the various (x, y, J, I)'s and K. These two equations are as follows:

$$\frac{y_1 - y_3}{x_1 - y_1} = K\frac{x_1 - y_1}{x_4 - x_1}$$

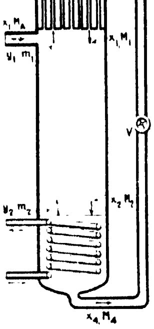
$$(J_1 - I_1)\frac{x_1 - y_3}{y_1 - y_3} = \frac{1}{K}(J_2 - I_2)\frac{x_4 - x_2}{x_2 - y_2} + I_1 - I_2$$

If we eliminate K from the second equation by means of the first equation, the second equation takes the form:

$$\frac{J_1(x_4 - x_1) - I_1(x_4 - y_1)}{x_1 - y_1} = \frac{J_2(x_4 - x_2) - I_2(x_4 - y_2)}{x_2 - y_2}$$

The value of x_4 as determined by the first equation is

$$x_4 = x_1 + K\frac{(x_1 - y_1)(x_1 - y_1)}{y_1 - y_3}$$



The equation shows that for given values of x_1 and y_3, x_4 is greatest when K is as great and y_1 is as small as possible. Whatever be the value of K, the minimum possible value of y_1 is that for phase equilibrium with the liquid of composition x_1, while for the arrangement as shown in the figure, the value of K is of the order of unity. Hence, under these conditions, the value of x_4 is limited and in general it will be impossible to make $y_3 = 0$ and $x_4 = 1$ together.

As an example, assume the mixture we are dealing with is of oxygen and nitrogen and let $x_1 = 0.21$. According to Baly's curves, $y_1 = 0.06$. Then if we assume that $y_3 = 0$ and $K = 1$, the maximum possible value of x_4 is

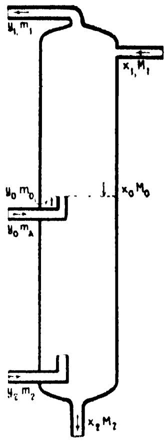
$$x_4 = 0.21\frac{(0.21)(0.15)}{0.06} = 0.73\tfrac{1}{2}$$

This limitation upon the composition of lower end product obtainable is present only in case the reflux liquid is produced in the manner exhibited in the figure and does not exist if we have available any desired amount of some extraneous liquid cold enough, when fed into the condenser, to cause condensation of the vapor m_1 as the latter ascends in the condenser tubes.

The example discussed in the preceding paragraphs is instructive in that it shows the importance of analyzing the relations existing in any proposed arrangement of apparatus.

Rectifier With Vapor Feed at Intermediate Level

Let us now consider the case where we admit a saturated vapor of composition y_0 at an intermediate point of the column, its mass m_A being the maximum amount possible under conditions of perfect rectification as heretofore defined. In what follows, we shall assume that the vapor m_A is added at a point in the column such that after it has been flowing steadily, the composition at this point of the vapor ascending from below is the same as the composition y_0 of the vapor admitted to the column at that point.



We shall find that, under these conditions, the quantity m_A is a maximum when the composition x_0 of the descending liquid at the level of admission of m_A is the same as that of the liquid having phase equilibrium with the vapor of composition y_0.

Under these conditions the six following equations hold, in which M_0 is the mass of descending liquid passing per unit time the level of admission of the vapor m_A, and m_0 is the mass of vapor ascending from below at this level.

$$M_1 + m_0 + m_A = M_0 + m_1$$
$$x_1M_1 + y_0(m_0 + m_A) = x_0M_0 + y_1m_1$$
$$I_1M_1 + J_0(m_0 + m_A) = I_0M_0 + J_1m_1$$
$$M_0 + m_2 = M_2 + m_0$$
$$x_0M_0 + y_2m_2 = x_2M_2 + y_0m_0$$
$$I_0M_0 + J_2m_2 = I_2M_2 + J_0m_0$$

These equations may be readily solved by properly interchanging subscripts in the solution of our three orginal equations for a simple rectification column. In this manner we obtain the following:

$$m_0 + m_A = \frac{(J_1 - I_1)(x_0 - x_1) + (I_0 - I_1)(x_1 - y_1)}{(J_1 - I_0)(y_0 - y_1) + (J_0 - J_1)(x_0 - y_0)} M_1$$

$$m_0 = \frac{(J_2 - I_2)(x_2 - x_0)(J_1 - J_2)(x_2 - x_0) +}{(J_2 - I_2)(y_2 - y_0) + (J_2 - J_0)(x_2 - y_2)} M_0$$

$$M_0 = \frac{(J_1 - I_1)(y_0 - y_1) + (J_0 - J_1)(x_1 - y_1)}{(J_0 - I_0)(y_0 - y_1) + (J_0 - J_1)(x_0 - y_0)} M_1$$

whence

$$[(J_2 - I_2)(y_2 - y_0) + (J_2 - J_0)(x_2 - y_2)]$$
$$[(J_0 - I_0)(y_0 - y_1) + (J_0 - J_1)(x_0 - y_0)]m_A$$
$$= \{[(J_1 - I_1)(x_0 - x_1) + (I_0 - I_1)(x_1 - y_1)]$$
$$[(J_2 - I_2)(y_2 - y_0) + (J_2 - J_0)(x_2 - y_2)]$$
$$-[(J_1 - I_1)(y_0 - y_1) + (J_0 - J_1)(x_1 - y_1)]$$
$$[(J_2 - I_2)(x_2 - x_0) + (I_2 - I_0)(x_2 - y_2)] M_1$$

In the special case where we are dealing with a mixture for which the total heat I at the boiling point and also the total heat J at the dew point follow the proportionality law indicated by the equations,

$$J = J_Bx + J_A(1 - x)$$
$$I = I_Bx + I_A(1 - x)$$

the above equations take the form

$$M_A = \left[\frac{x_0 - x_1}{y_0 - y_1} \cdot \frac{L_By_1 + L_A(1 - y_1)}{L_Bx_0 + L_A(1 - x_0)} - \frac{x_2 - x_0}{y_2 - y_0} \cdot \frac{L_Bx_1 + L_A(1 - x_1)}{L_Bx_0 + L_A(1 - x_0)} \cdot \frac{L_By_2 + L_A(1 - y_2)}{L_Bx_2 + L_A(1 - x_2)}\right] M_1$$

Now consider the special case where the incoming vapor m_A is a mixture of nitrogen and oxygen, and assume that we obtain pure liquid oxygen at the bottom of the rectification column and pure nitrogen vapor at the top, so that

$$x_2 = y_2 = 1$$

and

$$x_1 = y_1 = 0$$

Substituting these values in the equation just written giving the value of m_A, we obtain

$$m_A = \frac{x_0 - y_0}{y_0(1 - y_0)} \frac{L_1}{L_2x_0 + L_1(1 - x_0)} M_1$$

Now taking $y_0 = 0.21$, $x_0 = 0.47$, we obtain:

$$m_A = \frac{0.26 \times 598}{0.21 \times 0.79 \times 660} M_1 = 1.42M_1$$

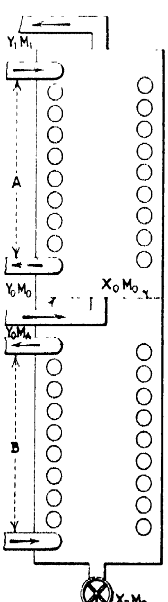
or

$$M_1 = 0.704M_A$$

From this result we conclude that if the liquid "reflux" nitrogen M_1 employed at the top of the rectification column is derived from an incoming mixture of air composition, it will be necessary to liquefy as liquid nitrogen about 70 per cent of that mixture in order to obtain complete separation.

The equations we have obtained in this section are very similar in form to those derived for the rectifier with liquid feed at intermediate level and may be utilized in a similar manner to obtain the conditions for minimum reflux.

A similar method may be easily applied to cases where any number of either vapor or liquid feeds are admitted at various levels in the column.



Rectifier With Distributed Condensation and Evaporation

In case the liquid descending in the column is formed by partial liquefaction of the ascending vapors themselves above the point of admission of the incoming vapor m_0, the above equations are modified. In the figure let A be a liquefying coil distributed throughout the portion of the column above the level of entrance of m_0 and let B be a vaporizing coil distributed in the column below that entrance level. The question as to the distribution of the condensing and vaporizing effects along the rectifier in order that the compositions of liquid and vapor in contact at all levels shall approach the relation for phase equilibrium we shall consider later in connection with a study of rectification as a reversible process. As before, let M_0 be the total mass of descending liquid at the entrance level of m_A and x_0

its composition. Let m_0 be the mass of vapor ascending from below at the same level and y_0 its composition, the latter being assumed to be the same as that of the incoming vapor m_A. Let M_2 be the mass of mixture leaving the bottom of the column and x_2 its composition, while m_1 is the mass of the mixture leaving the top of the column and y_1 its composition. Then between the five m's as defined, the four following equations hold:

$$m_0 + m_A = m_1 + M_0$$
$$y_0(m_0 + m_A) = y_1 m_1 + x_0 M_0$$
$$M_0 = m_0 + M_2$$
$$x_0 M_0 = y_0 m_0 + x_2 M_2$$

From these four equations the ratio between any two m's desired may be obtained.

Eliminating m_1, m_0 and M_2 from these four equations, we obtain as the relation between m_A and M_0:

$$m_A = \frac{x_0 - y_1}{y_0 - y_1} \cdot \frac{x_2 - x_0}{x_2 - y_0} M_0$$

which reduces to:

$$m_A = \frac{(x_2 - y_1)(x_0 - y_0)}{(x_2 - y_0)(y_0 - y_1)} M_0$$

or

$$M_0 = \frac{(x_2 - y_0)(y_0 - y_1)}{(x_0 - y_0)(x_2 - y_1)} m_A$$

Inspection of the equation last written shows that, since x_0 occurs only in the denominator and $x_0 > y_0$ the amount of descending liquid passing the entrance level of the vapor m_A and thus the mass of ascending vapor necessary to be liquefied in the column is least when x_0 is as great as possible.

The maximum value of x_0 possible to attain at the entrance level of m_A is the composition of that liquid having phase equilibrium with the incoming vapor of composition y_0, since the descending liquid at this point is in contact with that incoming vapor. Hence, if we assume that the compositions at this level are those necessary for phase equilibrium, the value of M_0 thus obtained—i.e., the mass of vapor necessary to be liquefied in the column—will be the least possible.

Continuation of this series of articles will be published in a subsequent issue.

Leaching Oxidized Ores by SO_2 Solution

A great deal of work has been done by the Tucson station of the Bureau of Mines on the leaching of copper ores by weak H_2SO_4 solutions, and the process has been determined to be commercially feasible. It is now planned to use this equipment for a series of trial runs on several types of oxidized ores from the Western states—starting on a complex ore from the Miami Copper Co.

Leaching of oxide copper is to approximate plant conditions as closely as possible. Precipitation will be by sponge iron manufactured at the Southwest station. Flotation for the recovery of cement copper will be by both violent agitation and pneumatic agitation type of cell. Re-use of discard solutions will supply all the ferrous sulphate required and the building up of impurities in the mill solution will be studied for possible adverse results. The plan calls for continuous daily plant operation. Several types of ores will be selected and representative samples carefully prepared such that each day of a particular run will have the same ore condition.

Legal Notes

BY WELLINGTON GUSTIN
Of the Chicago Bar

Chemical Use of Palladium Alloy

Court Holds It Was Conceived by F. A. Fahrenwald and His Right to Patent Is Indisputable

In interference proceedings between Charles A. Overmire and one Flynn, junior applicants, and Frank A. Fahrenwald, senior applicant, on applications for an invention for a utensil for chemical use, or a chemical resistant ware formed of an alloy, the Commissioner of Patents decided in favor of the application of Dr. Fahrenwald and his decision was affirmed on appeal to the Court of Appeals of the District of Columbia.

The invention was described in the opinion of the Commissioner of Patents as follows:

"The invention covered by the counts is a device variously denominated 'a utensil for chemical use' (count 1), 'a container for laboratory use' (count 2), 'chemical apparatus' (count 3), or 'chemical resistant ware' (count 4), made of an alloy of gold and palladium in proportions of about 1 of palladium to 5 of gold or silver."

USE OF PALLADIUM:GOLD ALLOY FOR OTHER PURPOSES IS OLD

The court found that the use of an alloy of palladium and gold for dental purposes, points of pencil cases, lancets and for numerous other purposes where strength and elasticity, coupled with the non-tarnishing quality, are required is old in the art. Hence the parties here were held strictly to the thing found to be patentable—that being "a utensil for chemical use."

The issue of the interference was set out in four counts, as follows:

"1. A utensil for chemical use consisting of an alloy of palladium and one or more of the noble metals of lower melting point in homogeneous solid solution, wherein the palladium forms not less than about 20 atomic per cent of the whole.

"2. A container for laboratory use, consisting of an alloy of palladium 10 to 40 per cent and gold 90 to 60 per cent in homogeneous solid solution.

"3. Chemical apparatus having a working surface consisting of an alloy of palladium and one or more of the noble metals, gold or silver, in homogeneous solid solution, wherein the palladium forms between 10 and 40 per cent of the whole.

"4. A heat and chemical resistant ware formed of a metal alloy of approximately 80 per cent gold and 20 per cent palladium."

Dr. Fahrenwald filed his application for patent July 13, 1916, which the court says constituted a constructive reduction to practice. The court found that this date is prior to any date to which Overmire and Flynn could lay claim. The latter, to substantiate their claim of priority, produced testimony to establish a production of a palladium:gold alloy in 1913 for use as a solder. But the court points out that that is not the invention of the issue. There was evidence, also, that prior to Fahrenwald's filing date they had produced a palladium:gold alloy for use as weights; but the court found

that such an alloy was old in 1880. Further they produced evidence to establish that as early as Nov. 25, 1914, they made an anode and a cathode, and these electrodes were successfully tested; but the court found there were publications showing the use of this alloy for electrodes as early as 1911. But, says the court, even if this were not old in the art, electrodes are neither "chemical ware" nor "chemical utensils."

And the Court of Appeals of the District of Columbia was convinced that Overmire and Flynn had "totally failed to prove reduction to practice, or even conception, of the use of the alloy of the issue for 'a utensil for chemical use' prior to Fahrenwald's filing date."

Hence the right to patent was found to be in Fahrenwald. (277 Federal, 618.)

Delay in Shipping Goods

When No Definite Time Is Specified for Delivery Circumstances Determine Reasonableness

Where the date fixed for delivery of goods under contract is important—that is, an essential part of the contract--a delay in the delivery is dangerous. Often such delay may be taken advantage of to refuse acceptance of the goods when laid down, and again the buyer may accept and use the goods and then set up damages caused by the delay as a counterclaim when sued for the purchase price. Again, the circumstances of the delay and the acts of the buyer may excuse the delay, or the buyer may have waived the requirement as to delivery under the contract.

Where no date for delivery has been set by the parties to a sales contract, the law makes delivery within a reasonable time sufficient. What is a reasonable delivery time is a question of fact arising out of the agreement and understanding of the parties at the time of entering into the engagement. Reasonable delivery might be a day or many weeks according to the circumstances of each contract.

In a recent action brought by the Lebanon Valley Iron & Steel Co. against the American Shipbuilding & Dock Corporation to recover the contract price of a quantity of galvanized iron spikes manufactured by the plaintiff for the defendant on the buyer's order, the United States Circuit Court of Appeals has held that a delay in delivering an article to be manufactured does not entitle the buyer to rescind without notice to the seller of such recision.

Buyer Gave No Notice of Intention to Rescind

In this case the order was given for galvanized spikes and other products of the steel plant. The order contained the following: "Please ship this material at the earliest possible date."

The order was given in September and the spikes were not shipped until the following March, 6 months afterward. Correspondence between the parties 3 months after the order was placed showed that more or less of the material was yet to be delivered, and the court said it implies acquiescence by defendant buyer in such future shipments. Neither then nor afterward, until the spikes were actually shipped, did the buyer give any notice, formal or informal, that they would be refused on account of delay in making delivery. The court further found that although the order called for shipment "at the earliest possible date," the buyer at no time thereafter requested prompter deliveries than were actually made, gave no intimation that it objected to the delay, but impliedly assented thereto in its letters to the manufacturer and otherwise, allowed the manufacture of the spikes to be completed without protest or notice of any sort, and then, when they arrived, refused acceptance on the ground that plaintiff had broken the contract by failing to ship at an earlier date. Buyer's sole defense for non-payment was the time that elapsed between the order and the delivery.

Under the above-stated facts and circumstances the District Court gave judgment for the buyer against the manufacturer and seller, but the Court of Appeals reversed the judgment and awarded a new trial to the seller. It says buyer's defense cannot be sustained under these facts. The contract in question fixed no definite date for performance. It says the buyer understood that the articles ordered were to be made by the seller and therefore could not have expected immediate delivery. A substantial period of time, sufficient for the manufacture, was necessary in contemplation. Moreover, under conditions then prevailing and of which the buyer was fully aware, delays in filling such orders were often unavoidable and always to be taken into account. This being so, the higher court says that buyer "could not remain silent, accept partial deliveries 3 and 4 months after the order was given, make no objection to further delay in shipping the balance of the order, seemingly acquiesce in what plaintiff was doing, and then upon tender of the spikes, barely 6 weeks later, refuse to receive them for no other reason than the lapse of time since they were ordered."

The Law Defined

The settled rule of law is that when the contract fixes no definite date for performance, notice of the intention to rescind the contract is a prerequisite to the right to rescind. And the right to rescind because of delay must be asserted promptly.

The rule is stated in volume 6, "Ruling Case Law," page 932, as follows: "The failure of a party to perform his part of a contract does not *per se* rescind it; the other party must within a reasonable time give notice of his intention to rescind. A formal or written notice is not necessary, but the law requires, on the part of him who would rescind, some positive act which shows such an intention."

And it is laid down in 9 Cyc., 613: "When no time has been fixed for the performance of a contract, either party may limit a reasonable period within which it must be performed by giving the other party a reasonable notice."

In the case as set out above the court says the fact that the goods were to be manufactured, to say nothing of the conditions then existing in the industry, made shipment "at the earliest possible date" a plainly indefinite, if not uncertain, time. The mere lapse of time did not serve to relieve the buyer from obligation, and the indefinite date for delivery did serve to put upon him the duty of giving reasonable notice of its intention to rescind the order. Its continued silence carried the implication of assent to the delay.

As to whether delivery was made within a reasonable time the court said the difficulties attending the manufacture of the spikes and their delivery at that particular time were proper and necessary as bearing directly on the question of reasonable time. So 6 months' delay was not unreasonable time for delivery in this case.

Electric Enamel Furnace Lowers Rejections on Stove Parts

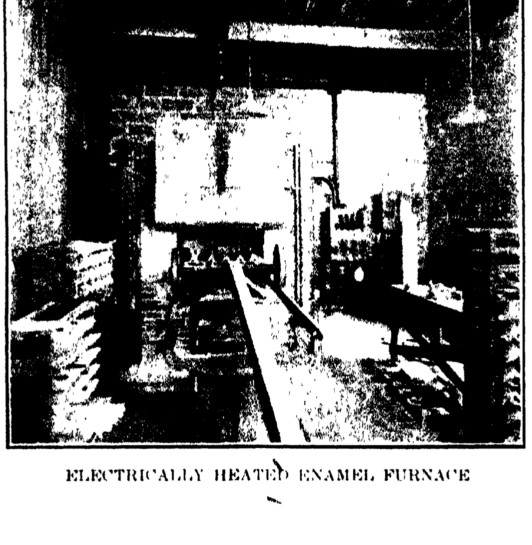
Cast Iron and Sheet Steel Enameled in Electric Furnace Operating on Schedule Which Insures Minimum Power Rate

AN installation of heating equipment that is interesting both as a new application of the electrically heated vitreous enamel furnace and because of some of the factors connected with its operation has recently been made by the Galusha Stove Co., of Rochester, N. Y., maker of high-grade enameled gas and combination ranges. The furnace is used for two classes of work, that of baking vitreous enamel on cast-iron stove parts, and on sheet steel. It operates at from 1,200 to 1,400 deg. F., with a maximum temperature range of 2,000 deg. F., and has a connected load of 118 kw. at 230 volts, three phase, sixty cycles. Its capacity is normally estimated at approximately 7 lb. of metal per kw.-hr.

Furnace Construction Insures Uniform Heat Distribution

The equipment consists of the furnace proper and the automatic control panel and instrument. The furnace is constructed of brick, with a refractory lining, having a sliding door that gives access to the upper compartment from the front. The dimensions of the overall working space are 5 ft. deep by 3½ ft. wide by 23 in. high. The interior is divided horizontally into two compartments by narrow shelves on each side wall, which support the sides of the tray on which the work to be baked is set. The nickel-chromium heat units are mounted away from the side walls and are about evenly distributed between the upper and lower compartments. This arrangement, together with the curved roof, causes the heat to strike the charge from all directions, and makes for a very uniform heat distribution throughout the furnace interior. The temperature is automatically controlled by a Leeds & Northrup temperature control instrument and an automatic control panel carrying contactors and overload relays. The heating elements and the control panel are of General Electric Co. manufacture.

The two classes of material require for their baking two temperature settings and durations of baking. The cast-iron stove parts are baked for 9 minutes at a temperature of 1,250 deg. F. and the sheet steel for 4 minutes at 1,400 deg. F. The company operating the furnace buys power from the central station on what is known as a three-rate schedule, whereby power used at a steady demand for 24 hours a day earns the lowest power rate. A schedule has been worked out for the operation of the furnace so that its running periods are dovetailed with those of the other power-using devices in the foundry of the plant, with the result that no additional demand is created during the daytime. By this method the operating expenses of the furnace itself are held to a very low level. Also, by not running the furnace in peak hours through the winter months, further economy has been effected in the operating cost. The overall economy that has resulted from the use of the furnace is due, in addition to the factors already mentioned, to the speed with which the material is finished, the reduced attendance necessary, and, most important, to the perfection of the finished product.



ELECTRICALLY HEATED ENAMEL FURNACE

Percentage of Rejects Small

In regard to the latter item, the percentage of rejects from the electric furnace is only about 4 per cent by weight of all the material baked. This percentage is remarkable in this special case, because a large portion of the work baked is enameled in white or light gray, colors that are very susceptible to spoilage from a contaminated atmosphere, either in the furnace itself or in the neighborhood. It has been possible, in the case of this factory, to save both space and time by installing the spraying equipment in the same room with the furnace and to assemble the sprayed parts on trucks in close proximity to the furnace, where they are left until their turn comes. Furthermore, the furnace has been operated by men who previously had little or no experience, either with electric furnaces or with enameling itself.

Present Situation in Rubber Sundries Trade

In a paper entitled "A Bigger and Better Sundries Trade," given by Fordyce Jones in Manchester recently, it was stated that the rubber industry at present might be described as being at the crossroads. In order that it might advance, it was essential to create demand and, through salesmanship and systematic advertising, to increase sales. Although the industry was originally founded in England, British rubber sundries are inferior to those of other countries in many instances. British manufacturers have acquired the reputation of regarding innovation with disfavor and of possessing very little knowledge of the development of the industry in other countries. Moreover, very few inventions were really taken up by the public and frequently the dealers who attempted to sell them were heavy losers. The consequent fear of failure was in reality the chief deterrent to the advancement of the industry in Great Britain.

As an example of the differences existing between British and American rubber sundries, surgeons' gloves were discussed. For this purpose, hard rubber is essential and must not be overmilled. It is important also to use a solvent free from residue. To be sure, solvent is very much cheaper in America, where, moreover, there is no amateur dipping or curing. Every operation is mechanical there and the glove is never touched; the cure is by vapor. In many respects, therefore, Great Britain could learn considerable from America concerning the rubber sundries trade.

Synopsis of Recent Chemical & Metallurgical Literature

Character and Uses of Peat

A very fine bulletin has just been issued by the U. S. Geological Survey describing the peat industry of the United States and its opportunities. This is Bulletin 728, entitled "The Occurrence and Uses of Peat in the United States," by E. K. Soper and C. C. Osbon.

In this bulletin are summarized very completely the chemical and physical properties of peat deposits, including those of commercial importance and others that at present offer no promise of economic development. The application of peat in fertilizers, as a filler in feeding stuffs and as a fuel for local use in territory where coal is scarce or very high will justify careful consideration of the bulletin by anyone interested in this business. It may be obtained on application from the U. S. Geological Survey, Washington, D. C.

Important Articles in Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department, but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

Thomas and Petree Process of Sugar Clarification in Hawaii

A discussion of a sugar process by S. S. Peck deserves respectful consideration and therefore the January number of the *International Sugar Journal* received unusually careful attention. The application of Dorr thickeners to sugar clarification by means of the Thomas and Petree process has been carried out in over forty plants in various parts of the world, but never before has there been an installation in Hawaii. The process involves a different routing of juice from the mills and a strategic insertion of two thickeners. The limed juice from the first mill passes through a preheater and thickener and goes immediately to the evaporators. Along with this there goes the clarified juice from the second mill. The strained juice from the second mill is limed separately and the mud from the first juice thickener is added to it. This mixture is preheated and clarified, the juice as indicated then going in with first mill juice and the mud is returned and added to the third mill juice, which in turn is returned to the first mill.

Thus it will be seen that there are three closed cycles, the mud finally going to waste (or fuel) with bagasse and the plant delivering one grade of clear liquor to the evaporators.

The advantages are many and will be briefly listed.

1. Character of the mud. The process calls for a slightly alkaline settling first and then an acid clarification at a somewhat higher temperature. This produces what is described as a stabilized mud which is more firmly fixed by the bagasse with a consequent diminution in the solution of insolubles.

2. Clarification of the juices. The juice from the first mill settles much better. Thus the Thomas and Petree process make use of this fact in returning the first mill mud to the second mill juice to aid in its clarification. This is a distinct improvement and in settling the first mill juice the Dorr equipment reduces the per cent of suspended matter and a more brilliant juice is obtained.

3. Automatic liming equipment.

4. Diminution in the percentage of juice in the mud from 10 to 25 per cent to 5 per cent.

5. The return of the mud to the rolls produces no ill effects on them due to the continuous nature of the process. Other attempts to add mud to the cane have been unsuccessful because of the unevenness of the addition and to the different character of the mud.

6. No definite data on extraction were available, but calculations indicated the return of 5 per cent juice to the second mill would result in a slight drop in extraction. An actual increase is mentioned in some instances by the inventors.

7. Effect on boiling. Clearer juices should make for less evaporation troubles.

8. Effect on fuel. Unexpectedly the clinker in the furnaces disappeared with the return of the mud.

In addition to the already enumerated items the undetermined losses will be fewer; some fuel will be saved, because of the elimination of the water used in sweetening of the cake; considerable labor will be saved, including all of the press men and some of the settling tank force. Finally, there will be a saving of material such as filter press parts, mud pumps and cars, etc.

A DISADVANTAGE WHICH MAY DEVELOP

This has to do with the value of the filter press cake as fertilizer. Although data on this point are a little confusing, there semes to be no doubt that the press cake has distinct fertilizer value, and an estimate of the economic value of the material should be subtracted from the financial gains which the process can show.

The financial advantage of an installation has been carefully estimated for a plant of assumed capacity and operating methods. The specifications are given in full in the article; there is need, however, only for a summary here. The plant grinding 200,000 tons of cane and producing 25,000 tons of sugar should make a total saving of \$41,478. If we subtract from this the interest on the investment in the Dorr equipment, the value of press cake as a fertilizer, etc., we should have a net gain of \$23,428, or 39 per cent on the investment over and above the normal interest rate.

An Interesting Note on Propyl Alcohol

The *Pharmazeutische Zentralheften* (No. 31, 1922) declares that propyl alcohol is of unusual merit as a disinfectant to be used on the skin. It is said to be at once a strong germicide and harmless to the skin and is used in solutions of from 35 to 50 per cent strength with good results on facial acne and disorders of the scalp. Poultices containing 10 to 20 per cent solutions are said to have been successful in treating bacterial eczema.

Recent Chemical & Metallurgical Patents

American Patents Issued Feb. 6, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,443,983—Process for Obtaining Paraffine and Highly Viscous Lubricating Oils From Bituminous Masses. Ernst Erdmann, Halle-on-the-Saale, Germany.

1,444,051—Fire Resisting Composition. Charles Ridgely Allison, Peekskill, N. Y.

1,444,068—Process of Manufacturing Anthraquinone and Phthalic Anhydride. Harry D. Gibbs, Pennsgrove, N. J., assignor to E. I. du Pont de Nemours & Co., Wilmington, Del.

1,444,129—Method of Converting Hydrocarbon Oils. William F. Muehl, Kansas City, Mo.

1,444,160—Method for the Precipitation of Iron in Aluminous Solutions. Thor Mejdell, Skoien, near Christiania, Norway, assignor to Aktieselskabet Labrador, Christiania, Norway.

1,444,162—Ceramic Bonded Carbide Article and Method of Making Same. Milton F. Beecher and MacDonald C. Booze, Worcester, Mass., assignors to Norton Co., Worcester, Mass.

1,444,178—Method for Commercially Obtaining Water-Soluble Milk Albumen and Milk Sugar. Adolph D. Fest, Chicago, Ill.

1,444,208—Process of Fractionation. Harry F. Perkins, Pittsburgh, Pa., assignor to Rosanoff Process Co., Pittsburgh, Pa.

1,444,250—Preparation of Active Animal Amylase and Process of Making Same. Richard Kern and Georges Jenny, Basel, Switzerland, assignors to Swiss Ferment Co., Ltd., Basel, Switzerland.

1,444,255—Method of Producing Cyanamide. Johan Hjalmar Lidholm, Wargon, Sweden.

1,444,257—Process of Producing Colloidal Soluble Substances and Suspensions. Leon Lilienfeld, Podhrace, Poland.

1,444,276—Manufacture of Wine-Yeast Preparation. Friederich Sauer, Gotha, Germany.

1,444,277—Manufacture of Dyestuffs. Maximilian P. Schmidt and Heinrich Roese, Biebrich-on-the-Rhine, Germany, assignors to Kalle & Co., Germany.

1,444,309—Manufacture of Cement Mixtures. Fabio Ferrari, Rome, Italy, assignor to the Company Bombrina Parodi-Delfino, Rome, Italy.

1,444,331—Cellulose Ether Composition. Stewart J. Carroll, Rochester, N. Y., assignor to Eastman Kodak Co., Rochester, N. Y.

1,443,333—Nitrocellulose Composition. Hans T. Clarke, Rochester, N. Y., assignor to Eastman Kodak Co., Rochester, N. Y.

1,444,406—Cellulose Ether Composition. William R. Webb, Rochester, N. Y., assignor to Eastman Kodak Co., Rochester, N. Y.

1,444,421—Process and Apparatus for Burning Powdered Coal. Alonzo G. Kinyon, Chicago, Ill., assignor to Fuller Engineering Co., Allentown, Pa.

1,444,484—Metallurgical Process for Treatment of Zinc Compounds. Earl P. Stevenson, Cambridge, Mass., assignor to Arthur D. Little, Inc., Cambridge, Mass.

1,444,527—Furnace Refractory. Charles A. Scharschu, Pittsfield, Mass., assignor to General Electric Co.

1,444,548—Process of Manufacturing Leather From Intestines. Eugene Markus, Budapest, Hungary.

1,444,594—Process of Impregnating Plant Tissues With Ammonium Nitrate for Explosive Purposes. William M. Lehn, Seattle, Wash.

1,444,623—Method of Producing Carbonates of the Alkaline Earth Metals. James H. MacMahon, Saltville, Va., assignor to the Mathieson Alkali Works, Inc.

Complete specifications of any United States patent may be obtained by remitting 10c to the Commissioner of Patents, Washington, D. C.

Chlorinating Hydrocarbons — In the direct chlorination of organic compounds, by the use of a catalyst, such as activated carbon, it has been found that certain undesirable chlorinated compounds with a boiling point higher than that of the compound which it is desired to make are formed during the early stages of the reaction, and these compounds are believed to impede the action of the catalyst by condensing on it in liquid phase. Herbert H. Dow has patented a procedure to overcome this difficulty, the patent being assigned to the Dow Chemical Co., Midland, Mich. In a specific illustration of the improved process the patentee describes the chlorination of the acetylene. Upon bringing chlorine in contact with acetylene in the presence of a porous catalyst, such as activated carbon, a number of substitutions or addition compounds are formed, the most conspicuous as well as the most desirable being the tetrachloride. The formation of these compounds begins at a temperature as low as from 40 to 50 deg. C., whereas the boiling point of such compounds ranges from approximately 60 to 200 deg. C., and upward, the boiling point of acetylene tetrachloride, for example, being approximately 140 deg. C. As a result of the initial reaction taking place in this process of chlorination, compounds may be formed which will not be in the vaporous state at the temperature at which the reaction occurs, and even though the temperature may be raised quite frequently they may still continue present in the carbon or other catalyst to such an extent as to affect its activity materially. When the activity of the catalyst has been reduced to a certain point, the flow of the reacting substance is shut off and the reaction chamber is placed under a vacuum so that the high-boiling compounds are vaporized. After such evaporation the reaction is resumed under the former conditions. The undesirable products are, of course, withdrawn in the vaporous condition and may be condensed and separated by fractional distillation or by chemical means. (1,437,636. Dec. 5, 1922.)

Rubber Vulcanization—S. M. Caldwell of Leonia, N. J., has assigned this patent to the Naugatuck Chemical Co., together with patents 1,440,962 and 1,440,963. All of these patents have to do with the vulcanization of rubber and the product obtained thereby. They are continuation of a number of serials filed previously. In the three patents there are a total of 150 claims, and all of them deal with the use of various types of vulcanizing agents, starting with compounds like zinc ethylxanthogenate. Various metal salts, such as zinc, mercury lead, copper, etc., are used and organic compounds having a general structural formula represented by

$$\begin{array}{c} RCSM \\ \| \\ X \end{array}$$

They are divided into three general groups, the first group being the metal thiol salts, the second group being bisulphides, and the third group being monosulphides. It will hardly pay to go into this elaborate patent more thoroughly, for it seems to be basic for a wide variety of products belonging to this group. (1,440,961. Jan. 2, 1923.)

Smokeless Powder—Tenney L. Davis, of Somerville, Mass., has patented the use of certain nitrogen compounds of the type known as heterocyclic for gelatinizing agents for the manufacture of smokeless powder. Specifically mentioned among such substances are the substituted pyrazolones and pyrazolidones. The formulas of the unsubstituted parent substances are as follows:

$$\begin{array}{ll} CH - N & \\ |\qquad\quad > NH & \\ CH_2 - CO & \end{array} \qquad \begin{array}{ll} CH_2 - NH & \\ |\qquad\quad > NH & \\ CH_2 - CO & \end{array}$$

Pyrazolone Pyrazolidone

Phenyldimethylpyrazolone, which is extensively used in medicine under the name of antipyrine, is also claimed to be excellent for the purpose. The advantages claimed for this invention reside in the fact that powders coated with the substance will be less hygroscopic than ordinary smokeless powder and will show a greater degree of progressive burning, giving higher velocity to the projectile while producing lower gas pressures in the barrel of the gun. (1,439,505. Dec. 19, 1922.)

Cellulose-Ether Solvent—Samuel E. Sheppard, of Rochester, N. Y., has taken out a patent covering the use of a solvent mixture for use in the plastic arts such as sheet or film and varnish manufacture. The feature of the patent is the employment of hydrogenation productions of the hydrocarbons and homologs. The hydrogenated substances are individual solvents of the cellulose ethers, but they may also be

employed in conjunction with other compounds, such as chloroform, ethyl alcohol, etc. Typical examples of the compounds used are tetrahydronaphthalene, or tetraline, and dekahydronaphthalene, or dekaline. These are high-boiling solvents and consequently can only be used in film dope in a mixture with other low boilers. A typical formula is given as 100 to 200 parts cellulose ether in a mixture containing 600 to 900 parts of chloroform, 300 to 450 parts ethyl alcohol, and 15 to 30 parts dekaline or tetraline, or mixture thereof. (1,441,181. Jan. 2, 1923.)

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Briquet Fuel—A composition fuel which is molded into block form is made up of 10 parts by weight of asphalt or pitch, 800 parts of fuel oil, 25 parts of shale and 45 parts of coal or coke, with or without 160 parts of tar, and 20 parts of peat impregnated with fuel oil. The shale and coal are finely ground and stirred in a mixing vessel into which steam is injected. Finely divided peat impregnated with oil may be added. The asphalt, and sometimes tar, and fuel oil are heated in a separate vessel and the mixture when liquid is combined with the shale, etc., the incorporated mass being molded on cooling (Br. Pat. 187,351. H. J. Franklin, London, and J. Pettingall, Chinford, Essex. Dec. 13, 1922.)

Bottle Capping Solution—A composition particularly adapted for sealing bottles consists of an agglutinant such as glue or silicate of soda, an earthy filling material such as talc, and an aqueous solution of soap and wax. A capsuling mass consists of 10 parts of leather glue diluted to 28 to 35 deg. Bé. mixed with 20 parts of talc and 3 parts of a solution containing 25 grams of hard soap and 40 to 50 grams of carnauba wax per liter. Coloring matter may be added. (Br. Pat. 187,611; not yet accepted. H. H. Warmund, Berlin. Dec. 13, 1922.)

Hydrogen Peroxide—Hydrogen peroxide of more than 10 per cent strength is obtained in one operation by treating an alkali perborate or a suspension in water of an alkali perborate with a mineral acid, such as sulphuric, hydrochloric or phosphoric acid, with agitation. Boric acid and the salt produced, such as sodium sulphate, separate. The perborate may be added to the concentrated acid, or the acid to a suspension of the perborate. (Br. Pat. 186,871. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler and O. Liebknecht, Frankfurt-on-Main. Nov. 29, 1922.)

Methane—Methane is produced by passing a mixture of water vapor with carbon monoxide or a gas, such as water-gas, containing carbon monoxide over two nickel contacts or sets of contacts in series, the water vapor being removed from the mixture between the two contacts. After elimination of carbon dioxide, the product consists of pure methane or methane admixed with a little hydrogen. For the second contact, nickel obtained from calcined nickel nitrate and maintained at a temperature of 350 to 400 deg. C. may be used; preferably, however, the nickel is prepared from nickel carbonate or organic nickel compounds and is employed at a temperature of about 300 deg. C.

In a second specification by the same patentee, the process described in the parent specification for the production of methane from carbon monoxide and hydrogen is modified by introducing carbon dioxide into the gas mixture either before the reaction starts or before it is completed. The theoretical proportions of carbon monoxide and hydrogen, namely 1: 3, may then be employed. According to the examples, (1) a mixture of carbon dioxide, carbon monoxide, hydrogen and nitrogen is passed over heated nickel, prepared by reducing precipitated nickel carbonate; water is then eliminated and the resulting gases are passed over a second nickel contact; after removal of water and carbon dioxide, the product consists of methane and nitrogen; (2) ordinary illuminating gas, completely desulphurized and freed from cyclic hydrocarbons, is mixed with a little carbon dioxide and circulated over reduced nickel with periodic separation of the water formed; the gas is then conducted over a further nickel contact and after cooling, the carbon dioxide is removed; a mixture of methane and nitrogen remains. Specifications 146,114 and 161,924 are referred to. (Br. Pat. 186,899. Farbwerke vorm. Meister Lucius und Brüning, Hoechst-on-Main. Nov. 29, 1922.)

Plastic Compositions—Four compositions containing peat are described for the manufacture of bricks, building blocks, etc.; (1) 70 parts by volume of peat, 25 parts of lime, 5 parts of sulphate of zinc; (2) 75 parts of peat, 20 parts of lime, 1 part of alum, 2 parts of tar, 2 parts of gypsum or silicate of soda; (3) 45 to 50 parts of peat, 45 parts of clay, 5 to 10 parts of silicate of soda; (4) 30 to 35 parts of peat, 60 parts of clay, 5 to 10 parts of silicate of soda. The peat as it comes from the bog is macerated, the other ingredients are added, and articles are molded. In the case of compositions 1 and 2, articles harden without artificial heat, other articles are burned. Reinforcements may be inserted during molding. (Br. Pat. 186,355. C. L. Hamon, Ballycumber. Nov. 22, 1922.)

Tungsten—In a process for the manufacture of tungsten suitable for electric lamp filaments, there is added to the tungsten compound before its reduction to metal a combination of two substances, one of which will introduce into the resulting metal an oxide irreducible by hydrogen, such as thoria or silica, and the other an alkali metal compound. For example, there may be left in the tungstic acid before its reduction 0.5 to 1 per cent of thoria and 0.03 to 0.3 per cent of sodium chloride, or 0.05 to 0.5 per cent of caesium chloride, the subsequent reduction, pressing, sintering, swaging and drawing being carried out in the usual manner. Specification 155,851 is referred to. (Br. Pat. 186,497. General Electric Co., Ltd., and C. J. Smithells, London. Nov. 22, 1922.)

Dyes—Triarylmethane dyes containing a thiazole ring are prepared by condensing tetramethyldiaminobenzhydrol or equivalent tetra-alkyldiaminobenzhydrol (in which one or two alkyl groups may be replaced by benzyl groups) with an arylbenzthiazole and oxidizing the resulting leuco compound. According to examples, tetramethyldiaminobenzhydrol is condensed with 1-phenyl-5-methylbenzthiazole, 4'-methoxy-1-phenyl-5-methylbenzthiazole, or dehydrothiotoluidine, and the leuco bases oxidized; the leuco base from dehydrothiotoluidine may be acetylated, or, according to the provisional specification, it may be alkylated or treated with phosgene. The products dye wool or tannin-mordanted cotton and also unmordanted cotton or paper, bright green shades.

1-Phenyl-5-methylbenzthiazole is prepared by heating benzyl-p-toluidine with sulphur.

4' - Methoxy - 1 - phenyl - 5 - methylbenzthiazole is prepared by methylating 4'-oxy-1-phenyl-5-methylbenzthiazole with methyltoluene sulphonate. (Br. Pat. 186,517. J. Braddiley, E. H. Rodd and H. H. Stocks, assignors to British Dyestuffs Corporation, Ltd. Nov. 22, 1922.)

Nickel—Nickel is deposited from nickel carbonyl by passing the gases containing the nickel carbonyl between a number of parallel heated surfaces arranged close together, say from ½ to 1 in. apart. Two forms of apparatus are described in the two specifications. (Br. Pat. 186,457 and 186,458. H. E. Fierz, Zurich. Nov. 22, 1922.)

Fatty Acids—Waste cellulosic materials such as wood waste are hydrolyzed to impure sugary worts, which, after purification, are subjected to symbiotic bacterial fermentation to produce fatty acids, mainly butyric acid. The hydrolysis of the disintegrated wood waste is effected by means of dilute sulphuric acid and superheated steam; the acid liquors are then neutralized with lime or chalk, the sugar solution extracted from the product by exhaustion, and purified from gums, resins, mucilages, etc., by adding excess of milk of lime, followed if necessary by passage of the decanted solution through animal charcoal. The purified wood wort is then treated with the ferments obtained by inoculating sugar solutions containing mineral salts with bacilli of the intestinal digestion of herbivora or contained in garden earth; by this means, all the reducible sugars of the wood wort are converted into acids—viz., butyric, acetic, propionic, valeric and caproic acids. The fermented wort is concentrated to a sirup preferably *in vacuo* and treated in a

still with sulphuric or hydrochloric acid or preferably sodium bisulphate to liberate the free organic acids which distill off and are fractionally separated. The carbon dioxide of the fermentation is recovered by absorption in sodium carbonate, from which it is freed by boiling. (Br. Pat. 186,572. Lefranc et Cie., Paris Nov. 22, 1922.)

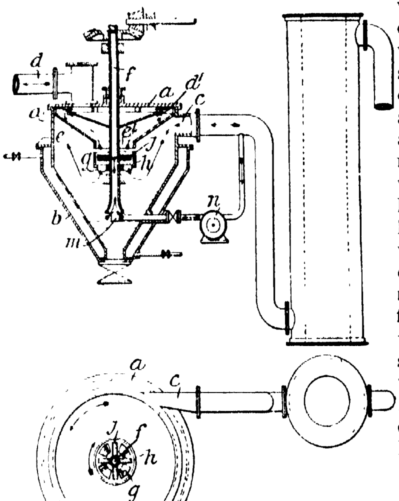
Desulphurizing Petroleum—In desulphurizing petroleum or petroleum distillates in the liquid state by adsorptive treatment with a dehydrated natural or artificial inorganic gel, the desulphurizing agent is used when freshly ignited and while still warm. Varieties of fullers earth such as floridin, or bauxite, or metallic hydroxides of a colloidal character, such as iron and aluminum hydroxides, may be used. The oil is mixed with the adsorptive substance or filtered through it. Means such as a steam-jacket may be provided to maintain the oil and adsorptive substance warm during contact. In treating benzine, 4 lb. of floridin or 9 lb. of bauxite per gallon is used. (Br. Pat. 186,955. A. E. Dunstan and F. B. Thole, Sunbury-on-Thames. Dec. 6, 1922.)

Soap—The lime sludge obtained by the action of soda on a lime soap is treated to remove residual soap by adding soaps of palm kernal oil, copranut oil or resin. The sludge is then lixiviated with water or weak salt solution and the lime carbonate filtered from the soapy solution. Palm kernel oil soap or copranut oil soap is added in such quantities as to amount to not less than 25 per cent of the total soap in the sludge after the addition, and resin soap to a corresponding minimum amount of 20 per cent. If the residual soap is wholly or mainly palm kernel oil soap or copranut oil soap, this addition is unnecessary. (Br. Pat. 186,960. P. Krebitz, Munich. Dec. 6, 1922.)

Iron Alloys—Workable low-carbon iron alloys containing chromium in smaller proportion than iron are made by blowing in a converter molten metal containing carbon, intentional overblowing being avoided. The charge to be blown may consist of ferrochromium diluted with pig iron, scrap steel, or other form of iron; or high-carbon iron may be mixed with low-carbon ferrochromium or high-carbon ferrochromium may be mixed with low-carbon iron; or both materials may contain carbon. Silicon is preferably present in or added to the charge in sufficient proportion to raise the temperature by oxidation during the blowing. The finished alloy is deoxidized by means of manganese or other deoxidizer. (Br. Pat. 186,982. J. C. Gillot, Sheffield. Dec. 6, 1922.)

Explosives—Mixtures of lead azide and lead trinitroresorcinate for use as explosive priming compositions are prepared by the simultaneous precipitation of the two salts or by the precipitation of one salt from a solution containing the other salt in suspension. *For example, lead azide is precipitated by the addition of sodium azide to a solution of acetate of lead containing lead trinitroresorcinate in suspension.* (Br. Pat. 187,012. E. von Herz, Berlin. Dec. 6, 1922.)

Treating Gases—Relates to the treatment of gases or vapors with a liquid medium, which may contain catalytic or other solids in a mechanical or colloidal state in suspension therein, in centrifugal or cyclonic apparatus in order to cause the liquid or the suspended solid to absorb one or more constituents of the gases or else to promote a reaction between the gases and the liquid or the solid. The process may be employed for the simultaneous desulphurization and hydrogenation and oxidation of gases or oil vapors by means of catalysts and oxidizing agents in the presence of ammonia, which may be supplied by means of producer gas.



The centrifugal or cyclonic apparatus may be so constructed that the reaction may take place at a pressure above or below atmospheric.

In the preferred apparatus the gas or gases to be treated enter the treating vessel a tangentially and at great speed through an inlet c, the liquid containing the desired solid being kept at the desired temperature by means of a heating or cooling jacket b. The gas travels spirally around the inner surface of the chamber a and is forced by incoming gas downward toward the center of the apparatus, where it is forced by rapidly rotating propellers g vertically upward through a rotating basket or mixing chamber h carried by a central tube f, the gas being eventually forced through openings e^1, d^1 in baffle plates to the outlet d. While in the vessel a and during its passage through the basket h, the gas is mixed intimately with a portion of the liquid and contained solid which is forced up the center tube f by an injector m supplied with a portion of the gas by a compressor n, the liquid being discharged into the basket through radial pipes j and sprayed through perforations in the basket across the vessel a. Fresh liquid may be fed into the apparatus and spent liquid discharged continuously during the operation.

Any desired number of baskets may be mounted on the tube f, and two or more complete apparatus may be arranged in series or in parallel, the gases or vapors receiving the same or different treatment in each. The basket is preferably rotated in the direction opposite to that of the incoming gases, but where two or more baskets are employed in the same or different apparatus, they may be arranged to rotate in opposite directions. (Br. Pat. 186,945. J. F. Ward and H. Nielsen, London. Dec. 6, 1922.)

Lubricants, Cosmetics and Leather Dressing—Wax or crude bitumen, such as ozokerite, beeswax, montan wax, carnauba wax or Japan wax, is treated with an aldehyde, such as formaldehyde or furfural, in presence of an alkali, with or without addition of a ketone, such as acetone or methyl ethyl ketone, or a divalent or trivalent alcohol, such as glycerol or glycol. The product, after removal of the alkali by washing, may be added to mineral, tar, animal or vegetable oil, yielding viscous or paste-like products, which may be used as lubricants or cosmetics, or emulsified with water, forming salves or leather-dressing compositions. It may be mixed with 20 to 30 per cent of paraffine wax, ceresin, ozokerite or the like without affecting its properties. Instead of aldehydes, their polymerization products or substances, such as hexamethylene tetramine, capable of liberating aldehyde may be used. (Br. Pat. 186,950. Plauson's, Ltd., London. Dec. 6, 1922.)

Sulphuric Acid—The process described in the parent specification is modified as follows in order to obtain an acid of higher concentration. In one modification a solution of nitrosylsulphuric acid of above 58 deg. Bé. is supplied to each unit of the plant, a more elevated temperature being employed if necessary. In a second method, the central part of the plant is irrigated with a solution of nitrosylsulphuric acid of a lower concentration than that used in the fore and rear parts of the plant. The second method may be further modified by adding water to the units in the middle of the plant, the nitrogen oxides consequently liberated being recovered by subsequently irrigating with acid of the same concentration as that employed in the fore part of the plant. (Br. Pat. 187,016. T. Schmiedel, Nurnberg, and H. Klencke, Frankfurt-on-Main. Dec. 6, 1922.)

Turpentine Substitute—An oil, having the properties of oil of turpentine, is obtained by heating rubber waste to about 220 deg. C., condensing the vapors given off, and rectifying this liquid by distillation, preferably with steam. (Br. Pat. 188,008. C. Lefebvre, Seine, France. Dec. 29, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Tentative Program Arranged for A.C.S. Spring Meeting

Important Papers Announced by Divisions and Sections —Membership of Local Committees

THE spring meeting of the American Chemical Society will be held with the New Haven and Connecticut Valley sections, at New Haven, Monday, April 2, to Saturday, April 7, inclusive. All divisions and sections are planning extensive meetings with the exceptions of the divisions of Fertilizer Chemistry and Leather Chemistry. The local committees have nearly completed their arrangements and an interesting program, together with instructive excursions, is assured.

The dedication of the Sterling Chemistry Laboratory of Yale University will be held on Wednesday, April 4, and all members of the society are invited to attend the ceremonies and to inspect the splendid new building.

Divisional Programs

All divisions and sections, as enumerated below, will meet. All divisions and sections will have two full days at their disposal if needed.

Before the general meeting of the Division of Industrial and Engineering Chemistry there will be presented papers by men of national reputation dealing with various phases of industrial chemistry. A whole day will be devoted to a symposium on "Materials of Chemical Equipment Construction." Subject matter will include cement, galvanized coatings, paints, rubber, glass, enamels, stoneware, wood, iron alloys, synthetic resins, laboratory construction, lead, etc. Philip A. Singer is chairman of the symposium.

The Water, Sewage and Sanitation Division announces no special features, but enough titles of papers have been received to insure a good program for that Division.

The Agricultural and Food Chemistry Division will discuss general papers and especially those on jams, jellies, pectin, etc., the first day of the meeting, and the second day will be given over to a symposium on "Insecticides and Fungicides." This symposium will be in charge of F. C. Cook, Bureau of Chemistry, Washington, D. C.

The Division of Cellulose Chemistry is planning a symposium on the subject of "Oxycellulose, Cellulose Hydrate and Hydrocellulose."

The Division of Chemistry of Medicinal Products is planning an interesting meeting. Applicable papers in the related fields of organic chemistry and biology are particularly requested.

The Division of Organic Chemistry is planning a symposium on "Catalysis."

The Division of Dye Chemistry considers this an opportune time to describe and record the accomplishments and the trials of the American dye industry prior to the war and accordingly there has been arranged a symposium on "The Coal-Tar Dye Industry in the United States Prior to 1914." The secretary of the division asks anyone who has any facts bearing on this matter to write him at once. A complete picture is desired.

The Division of Physical and Inorganic Chemistry is arranging an interesting program.

There will be no meeting of the divisions of Fertilizer Chemistry and Leather Chemistry.

The Division of Petroleum Chemistry will hold a joint symposium with the Gas and Fuel Section on "Motor Fuels." The division also hopes to take part in the symposium on "Materials of Chemical Engineering Construction" to be held by the Division of Industrial and Engineering Chemistry.

The Gas and Fuel Section will have a program, including a symposium on "Motor Fuels."

A meeting of the local section chairman and secretaries will be held at New Haven, at an hour and place to be announced on the final program. Round table discussion will take place on the following topics: Sectional programs, sectional finances, sectional community service, employment, and intersectional meetings. The committee on a standard set of local section bylaws will make its report. Chairmen and secretaries are asked to come prepared to take part in this informal discussion. W. Lee Lewis will preside and E. M. Billings will act as secretary.

Papers for the Meeting

Titles for papers should be sent to the secretary of the appropriate division or section and not to the secretary of the society. Titles to appear on the final program must be in the hands of the individual secretaries not later than March 15. It should be stated whether or not a lantern will be required.

Those desiring to present papers should communicate with the proper division or section immediately in order to obtain any special instructions which may apply.

The Council recently empowered officers of divisions to request any paper in advance, in order that it might be passed upon and an indication made to the author as to whether he is to read the entire paper or to abstract it in order to give time for discussion.

By vote of the Council no papers may be presented at the meeting titles for which are not printed on the final program.

"By Title" should be placed on the announcement of any paper where the author is to be absent, so that members may understand in advance that the paper will not be read.

The following are the addresses of the divisional and sectional secretaries:

Divisions

Agricultural and Food Chemistry, C. S. Brinton, U. S. Food Insp. station, 134 S. 2nd St., Philadelphia, Pa.

Biological Chemistry, W. V. Bovie, 332 Elliot St., Milton, Mass.

Cellulose Chemistry, L. F. Hawley, Forest Products Laboratory, Madison, Wis.

Dye Chemistry, R. Norris Shreve, 43 5th Ave., New York City.

Fertilizer Chemistry, H. C. Moore, Armour Fertilizer Works, 209 W. Jackson Blvd., Chicago, Ill.

Industrial and Engineering Chemistry, E. M. Billings, Kodak Park, Rochester, N. Y.

Leather Chemistry, Arthur W. Thomas, Department of Chemistry, Columbia University, N. Y. C.

Chemistry of Medicinal Products, E. H. Volwiler, 4753 Ravenswood Ave., Chicago, Ill.

Organic Chemistry, R. R. Renshaw, Chemistry Department, N. Y. University, University Heights, New York City.

Petroleum Chemistry, W. A. Gruse, Mellon Institute, Pittsburgh, Pa.

Physical and Inorganic Chemistry, Graham Edgar, University of Virginia.

Oil Chemists to Meet in Hot Springs

The fourteenth annual meeting of the American Oil Chemists Society will be held at the Eastman Hotel, Hot Springs, Ark., on Monday and Tuesday, April 30 and May 1, 1923.

Tentative Program Arranged for A.C.S. Spring Meeting

Rubber Chemistry, Arnold H. Smith, Rubber Service Laboratories Co., 611 Peoples Savings & Trust Bldg., Akron, O.

Sugar Chemistry, Frederick J. Bates, Bureau of Standards, Washington, D. C.

Water, Sewage and Sanitation Chemistry, W. W. Skinner, Bureau of Chemistry, Washington, D. C.

Sections

Chemical Education Section, Prof. Neil E. Gordon, University of Maryland, College Park, Md.

Gas and Fuel Section, R. S. McBride, Colorado Bldg., Washington, D. C.

History of Chemistry Section, Dr. L. C. Newell, 688 Boylston St., Boston, Mass.

Section of Local Section Chairmen and Secretaries, Erle M. Billings, 481 Woodbine Ave., Rochester, N. Y.

Local Committees

Edward W. Morley, Honorary Chairman.

Ralph W. Langley, Chairman Hotels and Transportation Committee.

Treat B. Johnson, Chairman Executive and Program Committees.

Julian S. Gravely, Chairman Finance Committee.

C. H. Mathewson, Chairman Entertainment and Reception Committees.

A. J. Hill, Chairman Divisional Programs and Room Committee.

W. T. Read, Chairman Publicity Committee.

W. H. Whitcomb, Chairman Excursions Committee.

Blair Saxton, Secretary and Chairman Registration Committee.

P. T. Walden, Chairman Smoker Committee.

Mrs. John Johnston, Chairman Ladies' Entertainment Committee.

Reduced Railroad Rates

Reduced railroad rates to the New Haven meeting are assured, as in view of the expected large attendance the railroads have agreed to sell round trip tickets at one and one-half fare on the identification certificate plan applicable to all parts of the United States. Tickets may be purchased March 29 to April 6 on presenting an identification certificate obtained from the secretary of the society or from the secretary of any local section, and will be good returning until midnight of April 13. From Colorado (except Julesburg), Idaho, Montana, New Mexico, Utah and Wyoming, Oklahoma and Texas the limits are March 28 and April 14. From Arizona, British Columbia (on Great Northern Railway only), California, Nevada, Oregon and Washington, the limits are March 27 and April 15. Tickets must be validated at New Haven by agents at the regular ticket offices of the lines over which tickets read into New Haven. When validated they will be good for return leaving on any day within final limit. Passengers must reach original starting point within transit time shown on ticket, and in no case later than midnight of April 13, or, in case of special exceptions above stated, April 15.

Tentative Program

MONDAY, APRIL 2

10 a.m. Registration bureau opens in Byers Memorial Hall, Yale University, corner College and Grove Sts.

2:30 p.m.—Council meeting in Y.M.C.A. auditorium, second floor, Byers Memorial Hall.

7:30 p.m.—Councilors' dinner in Ball Room of Hotel Taft.

TUESDAY, APRIL 3

9 a.m.—Registration and reception of members and guests at Byers Memorial Hall.

10 a.m.—General public meeting, Woolsey Hall, Yale University. Addresses of welcome.

Response, E. C. Franklin, president, American Chemical Society.

General addresses by John W. Weeks, Secretary of War, and Francis P. Garvan, president, Chemical Foundation. Complete list on the final program.

1 p.m.—Dutch treat luncheon for ladies and men at University Dining Hall.

2:30 p.m.—General scientific meeting, Woolsey Hall, Yale University. Special addresses will be given, of which the following is one: Carl A. Alsberg, "Chemistry and Our Food Resources."

2:30 p.m.—Ladies will visit Harkness Memorial Quadrangle, Yale Art School, Yale Library or New Haven Historical Society Building. (Guide service will be provided.)

4:30 p.m.—Tea for ladies and men at Faculty Club on Elm St.

8:30 p.m.—Smoker for men at Yale University Dining Hall (special features). Admission by ticket.

8:15 p.m.—Theatre Party, complimentary to visiting women.

WEDNESDAY, APRIL 4

Dedication of the Sterling Chemistry Laboratory. John Johnston, chairman dedication committee. This day will be devoted to functions arranged by Yale University, the chief of these being the dedication of the new Sterling Chemistry Laboratory. The order of the day's program will be as follows:

11 a.m.—Dedication ceremony in the Sterling Chemistry Laboratory. The building will be presented to the university by the Sterling trustees and accepted by President Angell, who will turn the building over to the American Chemical Society for its divisional and sectional meetings. After a reply by President Franklin there will be a special address by Dr. Edgar F. Smith dealing with the history of chemistry in America, with especial reference to Yale.

1 p.m.—Luncheon in the University Dining Hall complimentary to invited guests, ladies and members of the American Chemical Society.

2 p.m.—During the afternoon the laboratory will be open for inspection.

4:30 to 6:30 p.m.—Informal tea in the Sterling Chemistry Laboratory.

8:30 p.m.—Public meeting in Woolsey Hall, open to men and women.

Award of the Joseph Priestley Gold Medal.

Address by a speaker of national reputation (to be announced in the final program).

THURSDAY, APRIL 5

9:30 a.m.—Divisional and sectional meetings—Sterling Chemistry Laboratory, Sloane Physics Laboratory, Osborne Memorial Laboratory and Hammond Metallurgical Laboratory.

2 p.m.—Divisional and sectional meetings—Sterling Chemistry Laboratory, Sloane Physics Laboratory, Osborne Memorial Laboratory and Hammond Metallurgical Laboratory.

3 to 6 p.m.—Ladies will be entertained with an automobile drive to places of interest around New Haven, and with a tea at the Country Club, opposite Lake Whitney.

6:30 p.m.—Fraternity and college alumni dinners, University Dining Hall.

8:30 p.m.—Indoor polo game by Yale University R.O.T.C. given in the Yale Armory, off Derby Ave., near the Yale Bowl. (This contest open to ladies and men and admission will be by ticket.)

FRIDAY, APRIL 6

9:30 a.m.—Divisional and sectional meetings—Sterling Chemistry Laboratory, Sloane Physics Laboratory, Osborne Memorial Laboratory and Hammond Metallurgical Laboratory.

1 p.m.—Luncheon for ladies at the Lawn Club, on Whitney Ave.

2 p.m.—Divisional and sectional meetings—Sterling Chemistry Laboratory, Sloane Physics Laboratory, Osborne Memorial Laboratory and Hammond Metallurgical Laboratory.

8:30 p.m.—Reception tendered by the New Haven Section to the visiting members of the American Chemical Society and their guests. An evening of informal sociability in Memorial Hall of Yale University. Dancing from 9:30 p.m. to 12. Supper will be served at 10:30 p.m.

SATURDAY, APRIL 7

Excursions to industrial plants, informal inspections, etc.

Final Program

The final program will be sent about March 24 to the secretaries of local sections, to the Council, to members of the New Haven Section, and to all members making special request therefor by mailing a postal card or the form printed herein.

N. Y. Chemists Discuss European Situation

W. S. Landis' Observations on Conditions in Germany Arouse Much Discussion

The American Electrochemical Society was host at a joint meeting of the four chemical societies having sections in New York City, in Rumford Hall on Feb. 9. There were two speakers on the program, Harold E. Bishop, of the Radium Company of Colorado, who spoke on the present situation in the radium industry, and W. S. Landis, chief technologist of the American Cyanamid Co., who gave some impressions gathered on his recent trip to Europe.

As Mr. Bishop explained in his introductory remarks, there was no particular connection between the two subjects of the evening's discussion unless it might be found in the fact that the present status of the radium industry in the United States is due to European competition. The original source of radium was the pitchblende deposits in Bohemia, which were finally abandoned in favor of the more extensive, although poorer, carnotite deposits in Colorado. Now the Colorado deposits have in turn been abandoned because of the discovery of some extensive deposits of a very high-grade ore in the Belgian Congo. A plant has been erected near Antwerp which will have a capacity of about 15 mg. of radium per month. The capacity of existing American plants has ranged from 1 to 1.5 mg. of radium per month.

Problems in the Sale of Radium

The sale of radium presents some very extraordinary problems. Its commercial development is comparatively recent, dating back only about 15 years It has been necessary for the radium companies to educate the public to the therapeutic value of radium and to educate the physicians of the country in its intelligent use. In the hands of an unskilled physician, radium is a dangerous agent. The sales organizations that have been built up by the American companies will be kept intact by a working agreement with the Belgian producers under which the American companies will market their product in this country.

Mr. Bishop outlined the method of mining and working the Colorado carnotite and the method of preparing the finished radium bromide for application in the treatment of cancer.

Conditions in Europe

Dr. Landis, after apologizing for the presumption of a chemist who attempts to discuss problems that puzzle economists, gave a very interesting discussion of conditions in Europe as he observed them on a recent 5 weeks' trip. England, he said, has not yet recovered from the post-war depression. Prices there are very high. The most encouraging sign in industry is the recent revival of the shipbuilding. The spinning industry is in bad shape because of German competition, serious on account of the low cost of labor in Germany.

Dr. Landis spoke enthusiastically of the industrial prosperity of Italy. Since the Fascisti have restored the industries to their rightful directors and are gradually driving the Communists out of power in the elections, industries are flourishing. The hydro-electric development of Italy's natural resources is being carried out on a large scale, he said.

Dr. Landis recounted the ludicrous complications arising in Germany from the wild fluctuations of the value of the mark. Wherever possible, he said, wages are being paid in advance, because otherwise, after working for 2 weeks at a certain wage, the workman finds that the value of the mark has depreciated to such an extent that he is unable to purchase even the necessities of life with his wages. Some of the German companies are paying wages in food and necessary supplies. Selling prices, wages and overhead are rising to keep pace with the fall of the mark. German business men are afraid of any attempt to stabilize the mark, because the upward momentum of selling prices, wages and overhead would soon carry the cost of production higher than the selling price and a panic would undoubtedly follow.

Dr. Landis emphasized the fact that since railroad rates are so ridiculously low there must be a tremendous drain on the capital of the railroads. Similarly, tremendous demands are made on capitalists to meet their payrolls, etc. He predicted that the occupation of the Ruhr will cut off the coal supply of Germany and shut down all the steel and chemical plants in Germany, except those south of Berlin.

Much Discussion Aroused

J. S. Negru, managing editor of *Chem. & Met.*, who led the discussion of Dr. Landis' paper, disagreed with the latter on several points. He pointed out that the figures quoted by Dr. Landis showing that in 1913 Germany exported 75,000,000 tons of material while in 1922 this total fell to 20,000,000 tons were deceptive, because they do not show the value of the goods. He inclined to the opinion that the 20,000,000 tons of material exported in 1922 was of far greater value in dollars per unit weight than was that of the 1913 exports. Paper and discussion aroused unusual interest and after the adjournment of the meeting informal discussion continued late into the evening, in the dining room.

Brick Kiln Laboratory Car Dismantled

The railroad car "Holmes," equipped with a field ceramic laboratory and used by the ceramic experiment station, Bureau of Mines, Columbus, Ohio, has been dismantled. The car has been making efficiency tests on fuel-burning practice at different brick kilns in the central district, and has recently completed its survey.

To Investigate Basis for Changes in Chemical Tariff

The Tariff Commission has begun work on a questionnaire to be used in field investigation of eight chemical commodities regarding which applications for changes in tariff rates under the flexible section of the new law have been submitted and which have reached this stage. The identity of the commodities involved will be announced about March 1, when the questionnaires have been prepared and are ready to be sent to the interests involved, according to present plans.

It is the intention of the commission to send agents into the field following these questionnaires, to assist in their preparation and to secure other data needed by the commission. When the field work is advanced sufficiently to form the basis for judgment as to the merits of the applications, those cases which present costs of production making it appear that the tariff rate is either too high or too low will be docketed for public hearing. It is not believed that any hearing will be held before April 15.

More applications for changes in the chemical schedule have been received than for any of the other schedules of the new tariff act, it is announced by the Tariff Commission.

Compiles Useful Data on "Where to Buy"

With the purpose of helping to meet the growing demand for information on research equipment and instruments the Research Information Service of the National Research Council has assembled catalogs and lists of research appliances issued by makers and dealers. Publications of nearly 500 domestic firms and nearly 200 foreign firms are now on file. They have been classified for effective use and a subject catalog of apparatus has been prepared. The Service has also an up-to-date list of manufacturers and distributors of research chemicals. If the Service cannot supply just the information desired, it can generally suggest some useful source of information —manufacturer, dealer or designer.

Chemical engineers and directors of chemical research who desire assistance in locating special instruments, apparatus or supplies for use in their laboratories are invited to avail themselves of the resources of this organization. The appropriate address for inquiries is Information Service, National Research Council, Washington, D. C.

Oil Refineries as Public Utilities

The State Legislature of California is considering a bill introduced by Assemblyman S. L. Helsinger of Sema, classing oil refineries in the state as public utilities and placing them under the jurisdiction of the State Railroad Commission.

Women's Clubs Urge Appreciation of Chemistry

Appeal to American Women Points Out Importance of Chemistry in Home and Everyday Life

A new and important phase of the growing appreciation of chemistry by the American public is emphasized by a pamphlet just issued by a committee of women representing various national women's organizations. The pamphlet is addressed to American women as members of the responsible American public. It urges that women assess anew the value of the intimate and unending service of chemistry to home, community and country and that they assume the obligations resting upon them to bring America abreast of the world's foremost nations in this branch of knowledge which literally underlies our physical and our economic life. The brochure is sent out under the names of Mrs. Thomas G. Winter, president of the General Federation of Women's Clubs; Miss Maude Wetmore, chairman of the women's department of the National Civic Federation; Mrs. Herbert Hoover, national president of the Girl Scouts; Miss Ada L. Comstock, president American Association of University Women, and Mrs. George Maynard Minor, president general of the Daughters of the American Revolution.

Behind in Organic Research

The burden of the message as set forth in the pamphlet is to the effect that this nation has fallen behind in the promotion of research in that branch of chemistry on which rests the preservation of health, the practice of medicine, the elimination of waste from the home and industry by the conversion of that waste into humanly usable products, the improvement and increase in our food supplies, and the conservation of our resources through a wider and more effective utilization of materials.

The pamphlet goes on to give a "sweeping glance over the broad fields of human concerns in which chemistry plays a part." The nitrogen cycle, the formation of coal, the synthesis of perfumes and dyes, fertilizers, rubber and other important chemical products and raw materials are described in simple language. Special emphasis is placed on the chemist as a civic beautifier, particularly in reference to smoke prevention and recovery of industrial waste products.

Pointing out that the growth of organic chemical research in America has been retarded by the lack of public appreciation, the plea concludes with suggested steps to remedy this national fault as follows:

Get the educators and scientists in your own communities in touch with the objective of your organization activity. Find out what bearing the development of chemical research has upon that objective.

Find out what research equipment personnel in your community and state and in the nation are devoted to the subjects in which you are interested.

Look into the educational systems of your own community and state, and learn what place is assigned in the curricula to chemistry. See what your local libraries have in the way of authoritative and interesting literature on organic chemistry.

Study carefully and decide for yourselves whether the organic chemical industries are necessary as an assurance of support of the American young men and women who may be induced to choose a career in the field of organic chemistry as a result of your enlivening activities.

When you have gathered this information through group study, take counsel with other groups of women who have been studying the same subject and with the men who are concerned and active in the development of organic chemistry and an organic chemical personnel in America.

With this information and with this counsel, formulate your own idea as to what national and state policies should be put into effect for the surest development and maintenance of an American organic chemical personnel adequate to our national needs.

Act in accordance with the judgment you have thus formed, and demand of those opposing your course of action a clear explanation of the motive and grounds of their opposition.

In concluding, the brochure voices a thought which is worthy of consideration. It is pointed out that it is the general sympathetic understanding of the creative achievements and purpose of chemistry which furnishes the favorable condition for the growth of creative research. "There are but a few great musicians, poets, painters and sculptors, but there are millions of lovers of music, poetry, painting and sculpture. The appreciation of the millions is the life-sustaining if not life-creating atmosphere of the masters of science as well as of art."

Paper Show Will Attract Many to New York

Feature Days and Educational Attractions Make Up Elaborate Schedule for Paper Week

A series of special days for different groups of visitors to the Paper Industries Exposition is being arranged for the paper show which will be held at Grand Central Palace the week of April 9. In arranging these special days, care is being taken to avoid conflict with the conventions of the American Paper and Pulp and National Paper Trade and their affiliated associations. On each of the special days, special programs will be arranged, with authorities on various lines of activity as the chief speakers.

Printers' and Publishers' Day has been set for Friday, April 13. Thursday will probably be selected as Clean Food Day, with the program devoted to the utilization of paper and pulp containers for the protection of food from filth. Thursday will also be a special day for the manufacturers and merchants in attendance at the conventions to be held during paper week at the Waldorf-Astoria. The tentative program for the American Paper and Pulp Association, which will have its annual meeting and banquet on Thursday, April 12, provides for the holding of a strong forenoon program, but leaves the afternoon open for those in attendance at the convention to visit the Paper Industries Exposition. The manufacturers will then be able after their visit to the exposition to return to the annual banquet in the evening. The holding of Printers' and Publishers' day on Friday gives the merchants and manufacturers an opportunity to spend the day in visiting with their customers at the exposition.

Badges to Admit to Show

In order to facilitate the attendance of the merchants and manufacturers at the exposition, the management has arranged to make the badges of the different associations the only requisite for admission, those wearing association badges being admitted free as guests of the managers of the big paper show. In order still further to facilitate their attendance, the American Paper and Pulp Association has arranged that not only the badges but the registration cards of those in attendance at convention sessions be recognized as passes to the exposition.

While these arrangements for the program of the Paper Week have been in the process of completion, the work of assigning exhibits to space in the exposition has not been lagging. There are now upward of fifty-five exhibitors who have either closed contracts for space or made reservations of space pending the closing of formal contracts. Two or three of the biggest of the paper-manufacturing companies are among those which are now planning to place exhibits, and one of these at least is considering the taking of several booths in order effectively to show its product.

Educational Features

The latest of the educational exhibits to be definitely closed is that of the Bureau of Foreign and Domestic Commerce, which has accepted the offer of space made by the exposition management and which is planning to make an effective presentation of the work done by the whole bureau in general and more specifically the activities of the paper division of the bureau.

Basing its plans on the belief that the exposition is to be an educational exhibit for the public, as well as a special showing of paper to printers and publishers and of paper-making machinery and supplies to the paper manufacturers, special invitations are being sent to the various schools interested in paper, either by its use or in its manufacture, to have their students attend. The students of Columbia University's chemical engineering course, for instance, will be invited to take advantage of the exposition.

Not the least notable of the student group to be invited will be the pupils in the printing schools conducted in New York and vicinity. They will probably be invited to attend on Printers' and Publishers' Day, when the printers will be invited to bring their questions, with the manufacturers of paper on hand ready to answer the questions of the printers, who after all are the largest group of customers of the paper industry.

"Tell Ford Yes or No," Sentiment in Senate

Proposal of Appropriation for Experimental Work on Plant No. 1 Brings Up Muscle Shoals Again

While the probabilities are much against any action on Henry Ford's Muscle Shoals proposition at this session of Congress, the friends of that offer contend that they still have a chance to obtain a vote not only in the House but in the Senate as well. The unexpected happens many times during the closing days of a Congress when unexpected alignments are formed in the frenzied efforts to get certain legislation through the jam. It is entirely conceivable that some trade may be effected which would permit of a vote on the Ford offer.

It is known that Senator Underwood's contention, made recently on the floor of the Senate, that since Mr. Ford's bid was submitted as a result of a formal request from the government it should be accepted or rejected, has impressed a number of Senators who are not advocates of the Ford proposal. During that debate it was contended that it is a universal rule of business ethics that when bids are invited, the bidders must be told whether their proposals are accepted or rejected. Senator Underwood characterized the long delayed action on the Ford offer as being a very cavalier way in which to treat any bidder. Senator Williams said it was worse than cavalier and suggested "puritanical" as the proper adjective.

No Excuse for Delay

Senator Underwood called attention to the fact that there no longer is any controversy about the completion of the Wilson dam, since each house has authorized the engineers to make the final contract for its completion. He pointed out that within 3 years at most a great electrical plant will be ready for operation at Muscle Shoals, and the issue before Congress is whether it is to be operated by private effort or as a government institution.

The debate in the Senate was brought about by an amendment proposed by Senator Norris suggesting an appropriation of $2,000,000 for the installation of new machinery in Nitrate Plant No. 1, so that the plant could be used for experimental purposes. He argued that such a proposal should not be objectionable to Mr. Ford, since he would have to conduct such experiments if his offer were accepted. The amendment was opposed on the ground that it would complicate the situation by additional expenditures, additional experimentation and additional contracts. The trend of the debate made it clear to Senator Norris that the amendment could not prevail and he therefore withdrew it.

Ladd Thinks Haber Process Hopeless

Senator Edwin F. Ladd, the only chemist in the Senate, rose to discuss the proposed appropriation. He urged speedy decision on the disposal of the Muscle Shoals property, but opposed the expenditure for experiments on the Haber process at Plant No. 1. He declared that the plant was built upon an assumption and resulted in a failure.

The Senator from North Dakota then went into considerable detail regarding explosions that have occurred in plants where the Haber process is used. He quoted newspaper accounts of the Oppau explosion and dwelt upon accidents which have occurred in the Haber plants in this country.

"Only a volcano could be compared with the Oppau explosion," he declared. "I maintain, Mr. President, that the science of nitrogen fixation has progressed far enough so that it is not necessary to erect a volcano in a civilized community to supply this country with nitrogen for its military explosives."

Equipment Association Appoints Committees

Announcement is made from the headquarters of the Chemical Equipment Association, 1328 Broadway, New York City, of the appointment of the following standing committees:

Ethics: D. W. Sowers, Sowers Manufacturing Co.; A. B. McKechnie, Parks-Cramer Co.; W. B. Tardy, Schutte & Koerting Co.

Standardization: E. H. Froman, Fuller-Lehigh Co.; Hamilton Allport, E. B. Badger & Sons Co.; Hubert Royer, General Ceramics Co.

Membership: J. George Lehman, Bethlehem Foundry & Machine Co.; M. A. Knight, Maurice A. Knight; T. C. Oliver, Chemical Construction Co.

Industrial Relations: Edward J. Fowler, Pacific Foundry Co.; E. J. Sweetland, United Filters Corporation; J. W. Bodman, William Garrigue & Co.

Business Extension: J. W. Spotten, United Lead Co.; H. N. Spicer, Dorr Co; H. P. MacGregor, Merrill Co.

Statistics: R. Gordon Walker, Oliver Continuous Filter Co.; C. W. Pearson, Buffalo Foundry & Machine Co.; P. S. Barnes, Pfaudler Co.

Legislation and Publicity: Irving Fellner, *Chem. & Met.*; H. T. Matthew, Quigley Furnace Specialties Co., Inc.; Paul O. Abbé, Inc.

Some of these committees are not yet active, because their members have not yet been able to get together, but the scope of activity and the methods to be followed by each of the committees are nearing final definition, and within the next few weeks it is hoped to have undertakings under way which will involve the co-operation of government officials and bureaus, leading figures in the various equipment using industries, and the members of the association.

The association has adopted insignia for use on the stationery of members and in advertising, etc. The insignia consist of a monogram of the initials of the association and the motto, "Better to Serve Industry."

To Fight Ford in Defense of Waterpower Act

National Committee Formed for the Purpose Points Out Evil of Establishing Precedent

Declaring that the terms proposed by Mr. Ford to the government for the leasing of the Muscle Shoals power site are in flagrant violation of the principles of the federal waterpower act of 1920, a voluntarily organized committee including in its personnel many of the men who, in official positions, worked for the passage of the waterpower act has voiced strong disapproval of the Ford proposal. The committee includes former Secretaries of War Garrison, Stimson and Baker; former Secretaries of the Interior Garfield and Fisher; former Secretaries of Agriculture Meredith and Houston; Governors Parker of Louisiana, Dixon of Montana, Gifford Pinchot of Pennsylvania, former Governors Allen of Kansas and Pardee of California.

A pamphlet is being circulated, written by Herbert Knox Smith of Hartford, Conn., who was Commissioner of Corporations under the Roosevelt and Taft administrations and who conducted an exhaustive investigation of the waterpower problem. In this article the original objects of the waterpower act are set forth and contrasted with the provisions of the Ford Muscle Shoals proposal. It is pointed out that the real vice of this proposal is not in the immediate money loss, but that it is a flagrant violation of the waterpower act, which was passed purely for the protection of the public. The points of violation are enumerated as follows:

> It is a grant for 100 years
>
> It provides for no rental payments whatsoever for the use of the site, and only an absurdly small rental for the use of the works built with government money.
>
> There is no provision whatsoever to prevent the making of excessive profit on the Ford company's actual investment, nor to require any transfer of such excess to the public.
>
> There is no regulation whatsoever of the distribution or use of the power.
>
> There is no provision that it shall be used for public service in any way.
>
> The Ford company is not required in any way to contribute to the cost of storage reservoirs hereafter built upstream Such reservoirs would enormously increase the value of the Ford company's site, and the government is now making a survey for such storage developments

The point made in the article is that the real danger of the scheme lies in its force as a precedent, since it would apply to all other developments, existing and future.

Germany to Pay Italy in Books

Italy has agreed to accept as part of the reparations due her from Germany books and scientific publications to the value of 4,000,000 gold marks. Italy will furnish a list of her requirements. The gaps in the collections in her public libraries have been carefully cataloged, and it is these gaps that Germany will fill. Many valuable scientific works published before the war will be assigned to Italy's scientific institutions and museums.

Liquid Oxygen as an Explosive

As an appropriation will be available July 1 for a further study of liquid oxygen explosives by the Bureau of Mines, the tests made recently at Martinsburg, W. Va., by Adolf Messer, a German manufacturer, were of particular interest to the specialists of the bureau who were present. George S. Rice, the bureau's chief mining engineer, who has done a great deal of work on liquid oxygen and who will be in immediate charge of the work to be done under the new appropriation, attaches great significance to the Martinsburg tests, since they show how successfully liquid oxygen can be used in deep holes. He believes that the use of liquid oxygen in shallow holes has been worked out thoroughly and demonstrated to be entirely practicable. For that reason he plans to devote most of the bureau's appropriation to the study of the technique involved in the shooting of deep holes with liquid oxygen.

Mr. Rice has no idea that there will be any extensive supplanting of dynamite by liquid oxygen, but under certain conditions he believes liquid oxygen can be used to greater advantage than other explosives. This is particularly the case in cities and congested areas, where the transportation of ordinary explosives is undesirable. He expects it to appeal to users where there is difficulty in preventing thefts of ordinary explosives and at times when outrages might follow the availability of explosive supplies which could be pilfered by misdirected persons.

Under some conditions, however, Mr. Rice believes liquid oxygen will be used in mining operations. He calls attention to the fact that nearly two-thirds of the iron ore mined in Lorraine is shot down with liquid oxygen. It is his opinion that conditions are ideal for the use of this explosive in Alabama iron mines. That it is reaching the point of practical use may be judged from the fact that a plant is about to be installed at a mine in northern New York. He does not believe its use is desirable in any coal mine, whether gaseous or not.

New Jersey Third State in Clay Production

According to a preliminary report compiled by the State Department of Conservation and Development, New Jersey, that state stands third among those of the Union producing clay and burned clay materials. The total value of pottery production for 1920, the year which the report covers, was $24,597,376, while that of brick and tile aggregated $15,423,652, a total of $40,021,028. According to the statistics, Ohio ranks first in the line of ceramic production with a total of 21.9 per cent of the aggregate output of clay products in the United States; Pennsylvania comes next with 13.6 per cent; and New Jersey follows with 10.7 per cent.

Personal

William Barr, formerly with the Los Angeles branch of the Hughes Tool Co., is now production manager for the Regan Forge & Engineering Co., San Pedro, Calif.

John A. Coe has been re-elected president of the American Brass Co., Waterbury, Conn., and Charles F. Brooker has been re-elected chairman of the board.

A. Clayton Clark, superintendent at the plant of the Raritan Copper Works, Perth Amboy, N. J., has been elected president of the local board of education.

W. D. Collins, of the U. S. Geological Survey, delivered an address before the Washington Academy of Sciences, Feb. 15, on the subject "The Industrial Aspects of Modern Methods of Water Purification."

L. C. Cooley has accepted a position as plant engineer with the United States Industrial Chemical Co., Baltimore, Md.

Edward A. Dieterle has resigned his position as chief chemist of the Chicago By-Products Coke Co. and is resuming consulting engineering work with headquarters in Chicago.

W. E. Emley of the Bureau of Standards recently delivered a paper before the Sand-Lime Brick Association.

Albert P. Matthews, professor of biochemistry, College of Medicine, University of Cincinnati, gave an interesting address at the meeting of the Indianapolis, Ind., section of the American Chemical Society, Feb. 9, at the Indianapolis Chamber of Commerce on the subject of "New Light on the Origin of the Organic Substances on the Earth's Surfaces"

George S. Rice, the chief mining engineer of the Bureau of Mines, has been selected as the bureau's delegate to attend the Mining Exposition and Conference which will be held in London, June 1 to June 14. He will sail from New York on May 12. Following the exposition he will visit other countries of Europe to continue his study of mining methods. He also will devote a considerable portion of his time to a study of the improvements made in the manufacture and use of liquid oxygen.

Dr. Hugo Schlatter will deliver a lecture before the Philadelphia Section of the A.C.S. on "The Manufacture of Artificial Silk" and will also be the principal speaker at the March meeting of the N. J. Chemical Society.

Dr. Edwin E. Slosson of Washington, D. C. recently addressed the Technology Club of Syracuse N. Y. on "Creative Chemistry."

James Vail of the Philadelphia Quartz Co. gave a paper last week before the American Ceramic Society. He will shortly sail for Europe to be gone about 2 months.

Obituary

Robert W. Hilton, president of the Hilton-Davis Co. and formerly vice-president of the Ault & Wiborg Co., died Feb. 5, following a 3-day illness at his home in Cincinnati. He was 49 years old. A complication of influenza and pneumonia caused his demise.

Lysle R. Kraus, secretary of the Kraus Research Laboratories, Inc., died Tuesday, Feb. 6, from the result of a railroad accident. Mr. Kraus was born Nov. 21, 1893, at Cockeysville, Md., was graduated from the Sparks Agricultural College in 1914 and was one of the founders of the Kraus Research Laboratories, Inc., and associated himself with the company in the capacity of ceramic engineer. In the ceramic field Mr. Kraus invented several processes for the plasticizing of clays and developed many bonding clays of exceptional value. His research work in refractories was very exhaustive—making improvements over present-day methods and producing several new refractory bases.

H. J. Seaman, for many years general superintendent of the Atlas Portland Cement Co., of 30 Broad St., New York City, died on Feb. 9, in Atlantic City. Mr. Seaman was a graduate of Lafayette College, Easton, Pa., and had played an important part in the building up of a very essential manufacturing industry, which has always been classed as a chemical industry since the early stages of its development. Previous to his connection with the Atlas Portland Cement Co., Mr. Seaman was associated with Mr. Hurry, a prominent English engineer, and together they introduced the use of pulverized coal for burning portland cement clinker in rotary kilns.

Arthur C. Stallman, president of Arthur Stallman & Co., crude drug merchants of New York, died Feb. 8, at his home in Mt. Vernon, N. Y., from pneumonia, at the age of 52. He was born Sept. 22, 1871, in New York. Mr. Stallman was the son of the late John Henry Stallman and Sophie M. C. (Frentz) Stallman. He became associated with his father in the crude drug firm of Stallman & Fulton, one of the earliest and best-known houses in that trade. His father died in 1908 and the firm was dissolved. In 1912 Mr. Stallman started the business that now bears his name.

Milton Franklin Williams, president of the Williams Patent Crusher Co., St. Louis, Mo., died Feb. 8, from septic pneumonia, although he had been confined to his home for the past 18 months suffering from diabetes. Mr Williams went to St. Louis more than 50 years ago and started as a millwright in a small machine shop. He originated the swing hammer crusher and pulverizer in 1895, and in 1897 incorporated his machine works under the present name.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Chemical Exports Show Gradual Recovery in 1922

Improvement at a Time When Total Exports Show Marked Decline Is Generally Regarded as Indicative of Better Business Conditions in Chemical and Allied Industries

CHEMICAL and kindred industries showed a surprising improvement in export trade during 1922. In the face of a decrease in general exports from $4,378,928,024 in 1921 to $3,765,192,135, the shipments of American chemicals showed a gain in aggregate value of 1.4 per cent. The figure for the year was $106,101,562, as contrasted with $104,639,941 during 1921. The chemical division of the Commerce Department points out that among the subsidiary commodity groups contributing to this gain, explosives rose 50 per cent in value over 1921, perfumery and cosmetics increased 33 per cent, medicinals and pharmaceuticals 11 per cent and fertilizers 3 per cent.

Pigments, paints and varnishes, it is also pointed out, have shown a steady although rather sluggish tendency to improve. However, the total for 1922 is 5 per cent below last year's. It is of interest to note that the 26 per cent decrease (from corresponding 1921 values) that marked the first half was compensated in large measure by the 31 per cent increase of the last half of 1922. The exports for December, 1922 ($1,096,320), were the greatest for any one month since February, 1921.

Encouraging Comment

Only three groups of American exports in 1922 showed an increase over the previous year; "chemicals and allied products" was one of the three. True, the gain was only 1.4 per cent, yet when this is set off against decreases ranging from 8 to 31 per cent for other groups, a feeling of satisfaction at the year's outcome is not unwarranted.

With a continuance of the spirit of organization and co-operation manifested during the past year there would seem to be no reason why the chemical industry should not now go steadily forward.—*C. C. Concannon, Acting Chief, Chemical Division, Department of Commerce.*

Coal-Tar Products Lagging

General chemicals failed to reach their 1921 level by 4 per cent, exports for 1922 having a total value of $51,712,005, contrasted with $54,041,996 a year ago. Foreign sales of benzol (64,740,402 lb., valued at $2,362,821) were 10 per cent in quantity and 21 per cent in value below those of 1921 (72,030,400 lb., worth $3,007,086). Coal-tar colors, dyes and stains other than color lakes likewise lost ground, dropping from $5,067,000 to $3,981,217, but crude coal tar increased from $191,482 (92,406 bbl.) to $208,666 (99,960 bbl.). Carbolic-acid exports decreased from $35,994 (219,658 lb.) in 1921 to $23,223 (223,146 lb.) in 1922.

Among other coal-tar products, $65,636 worth (341,820 lb.) of aniline oil and salts, $224,546 worth (554,166 lb.) of medicinals, and $103,853 worth (248,119 lb.) of photographic chemicals were shipped from the United States to foreign countries in 1922. The corresponding 1921 figures for these items are not available.

Foreign sales of wood and denatured alcohol doubled in value and tripled in quantity, rising from $454,584 for 412,110 gal. in 1921 to $922,700 for 1,270,314 gal. in 1922. A large decrease occurred in exports of other alcohol—from $2,338,838 for 5,611,897 proof gallons to $497,955 for 2,090,666 proof gallons.

Heavy Chemicals Show Important Gains

Heavy chemicals showing important expansions in quantity in 1922 over 1921 included copper sulphate, which increased 46 per cent, acetate of lime 51 per cent, bleaching powder 123 per cent, glycerine 20 per cent, potassium chlorate 50 per cent, sodium silicate, or water glass, 40 per cent, sal soda 10 per cent, and sodium bicarbonate 35 per cent; but the largest increases of all under this classification were in borax, which increased more than 300 per cent, and caustic soda, which rose nearly 200 per cent. Specific figures of the exports of these and other chemicals are given in Table I, which will be found on page 376.

Exports of sulphuric acid dropped off from $317,720 (12,814,344 lb.) in 1921 to $201,267 (12,470,389 lb.) in 1922.

Throughout 1922 the foreign demand for explosives was encouraging, growing until during December the peak was reached with 2,939,283 lb., valued at $504,942, exported. Total shipments abroad for the year were 19,212,449 lb., worth $3,400,391, compared with 10,433,830 lb., worth $2,285,849, in 1921. Of this group, the only class for which comparative figures are available is dynamite, with increases of 47 per cent in quantity (from 9,567,442 to 14,105,017 lb.) and 33 per cent in value (from $1,815,999 to $2,406,398). There were also shipped abroad during 1922 925,840 lb. ($369,848) of smokeless powder, 410,705 lb. ($129,216) of other gunpowder, 3,227,956 lb. ($366,686) of blasting powder, and 125,308 lb. ($54,267) of cordite, guncotton, etc.

Phosphate Rock Competition Expected

The expected drop in foreign demand for phosphate rock as a result of the recent development of the Moroccan phosphate mines has not yet materialized. The development of the Moroccan phosphate deposits is receiving serious attention, and competition with American phosphates is expected. During the next few years it will be interesting to observe the actual effect on American exports. Although sales of high-grade phosphate rock rose in quantity from 182,594 tons (value $2,592,541) in 1921 to 202,300 tons (value $2,548,587) in 1922, those of land pebble declined from 544,425 tons ($4,267,875) to 512,777 tons ($3,269,179) and of other phosphate rock from 6,293 tons ($99,721) to 4,217 tons ($40,401).

In addition to these fertilizers and fertilizer materials, there were shipped abroad in 1922 2,556 tons ($26,112) of calcium cyanamide 1,576 tons ($78,047) of other nitrogenous materials and 14,416 tons ($600,972) of prepared fertilizer mixtures.

"Chem. & Met." Weighted Index of Chemical Prices

Base 100 for 1913-14

This week	176.31
Last week	175.64
February, 1922	148.00
February, 1921	166.00
February, 1920	252.00
April, 1918 (high)	286.00
April, 1921 (low)	140.00

Included in this index are acetic, citric, hydrochloric, nitric, and sulphuric acids, ethyl and methyl alcohols, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, salt cake, soda ash, sulphur, benzine, aniline, and cottonseed and linseed oils.

Coal-Tar Products Show More Activity

Crudes in Scarce Supply—Intermediates in Fairly Good Demand—Material Improvement Generally Noted

The general market for coal-tar products appeared rather steady, and prices throughout the list were well maintained. Crudes continued in limited supply and producers reported a heavily sold up condition at the works. Phenol, cresylic acid, solvent naphtha and pyridine were in strong demand, but sales were rather small, due to the scarcity of stocks. Intermediates were held in strong producing hands and prices were fairly well sustained. Alpha-naphthylamine, aniline oil, H acid and beta naphthol showed considerable activity at prevailing quotations.

Dull Market for Chemicals

However, a Few Bright Spots Were Noticed—Calcium Acetate Selling in Good Quantity

Trading in industrial chemicals last week was rather dull in the New York market, due undoubtedly to the intervening holiday and the extreme conservatism shown by leading consumers. The transportation situation was slightly improved, but still far below normal.

Producers of oxalic acid announced another decrease in price, said to be due to the sharp foreign competition and the lack of consuming interest. Arsenic and its compounds continued to feature the spot market. Buyers experienced some difficulty in procuring any round lots for March shipment, due to the heavily sold up condition abroad and at the works. The alkali market is progressing along moderate lines and with some improvement resulting from the better railroad transportation. Buyers have been able to transact considerable additional business. Bleaching powder, caustic potash, prussiate of soda, sal ammoniac and barium chloride continued along fairly active lines at prevailing quotations. Slightly lower prices were noted for formaldehyde and carbonate of potash.

Price Changes

Bleaching Powder—Producers continued to quote \$2 per 100 lb., f.o.b. works, in large drums. Resale goods were held around 2½c. per lb. Demand was rather active, in view of the sold-up condition at the works.

Calcium Acetate—Leading producers quoted 3½c. per lb., f.o.b. works in bags. The demand was said to be good and the dealers expressed their satisfaction at the general volume of business.

Caustic Potash—The market appeared somewhat slower than previously noted, although prices were well maintained around 7¼@7½c. per lb. Shipments from abroad were quite firm at 7½c. per lb., c.i.f. N. Y.

Caustic Soda—Domestic consumers continued to purchase in fair-sized tonnages at \$3.75 per 100 lb. ex-store N. Y. Export business was quiet, with odd lots selling around \$3.40@\$3.45 per 100 lb. f.a.s.

Carbonate of Potash—Prices were fractionally lower, due to the lack of consuming interest. Calcined 80-85 per cent was quoted around 5¾c. per lb., with 96-98 per cent at 7¼@7½c. per lb.

Formaldehyde—Resale material was quoted somewhat lower, due to surplus stocks. Producers continue to quote 16c. per lb. in carlots and 16½c. in smaller quantities. Resale goods was quoted at 15½c. per lb.

Soda Ash—Leading dealers were quoting standard goods at \$1.75 per 100 lb., f.o.b. N. Y. in carload lots, single bags. The demand was merely routine, with actual transactions rather limited. Contracts continued at \$1.20 per 100 lb., basis 48 per cent, f.o.b. works in single bags.

TABLE I—EXPORTS OF CHEMICAL AND ALLIED PRODUCTS, 1921 AND 1922

Article	Unit of Quantity	1921 Quantity	1921 Value	1922 Quantity	1922 Value
Chemicals and allied products (total)			\$104,639,941		\$106,101,562
Coal-Tar Products					
Crudes—

Smaller Volume of Business in Chicago Market

Prices Are Well Maintained, but Dealers Are Showing Concern Because of General Inactivity

CHICAGO, ILL., Feb. 15, 1923.

Business in industrial chemicals has not been so good during the past 2 weeks and dealers displayed some concern over the change. The dullness of the market brought on some price cutting from worried holders, but in general prices were fairly well maintained. Spot stocks were in fair condition, but the poor freight service made shipments slow. Conditions abroad were getting worse instead of better and it is expected that in the near future material of foreign origin would be both high priced and scarce.

Principal Price Changes

The spot price on *caustic soda* was reduced 10c. per 100 lb. by leading factors. This reduction brings ground caustic to \$4.15 per 100 lb. and solid \$3.40. *Caustic potash* was very firm due to the scarcity of supplies and the situation in Germany. Spot material of the 88-92 per cent grade was held at 8@9c per lb., price according to quantity and the seller. *Soda ash* was in fair demand and was unchanged at \$2.25 per 100 lb. for material in cooperage.

Potash alum was scarce on spot and only small lots were available at 4½@5c per lb for the iron-free lump. The powdered grade was available only in one direction and was quoted at 8½c per lb. *Ammonium carbonate* was quiet and unchanged at 9@10c. per lb. for the lump. *Sal ammoniac* was available from one source at 7¾c. per lb., but the general quotation was 8c. *Barium chloride* was quiet at \$110 per ton. *Barium carbonate* of foreign origin was quoted in small lots at \$100 per ton, but with a fair-sized order this could have been shaded considerably. *White arsenic* was well maintained in price and only small lots were to be had at 17@17½c. per lb. *Carbon tetrachloride* was available from one dealer at 9½c. per lb., although the general asking price was 10@10½c. *Carbon bisulphide* was unchanged at 7½c. per lb for spot goods. *Copper sulphate* was quoted in some quarters at 6¼c. per lb., but odd lots were still available at 6c. *Formaldehyde* displayed no signs of weakness and was quoted at 17c. per lb. *Glycerine* was not so firm and there was less talk of an advance; c.p. material in drums was quoted at 18½c. per lb. delivered. *Lead acetate* was quiet and unchanged at 12½c. per lb. for white crystals.

Potash Salts Advancing

Practically all potash salts were very firm, with advances noted in several cases. *Potassium bichromate* was in fair demand and supplies were quoted at 12½@13c. per lb. *Potassium carbonate* 96-98 per cent was quoted at 9@10c. per lb. for delivery from stock. *Potassium cyanide* 96-98 per cent was to be had only in one direction and was quoted at 55c. per lb. in single-case lots and 2c. less for five cases. *Yellow prussiate of potash* was available at 40c. per lb and the red was generally quoted at 90@92c. per lb. *Potassium permanganate* was firm, with moderate lots of the U.S.P. crystals available at 18@19c. per lb.

Sodium bisulphite was in fair request and powdered material was generally quoted at 6c. per lb. Material for shipment from the East was somewhat cheaper. *Sodium fluoride* was quiet at 10@10½c. per lb. *Zinc chloride* granulated was quiet at 8c. per lb. for domestic material and foreign slightly lower.

The demand for *linseed oil* was far from heavy but the price continued to advance. Boiled oil was quoted today in single-drum lots at \$1.06 per gal., with similar quantities of the raw at \$1.04.

Turpentine was in a position similar to that of linseed oil. The movement was only fair, but the price was well maintained at \$1.53 per gal. in single-drum lots.

Advancing Market for Steel Products

Tendencies That Became Evident in January Have Resulted in Numerous Price Advances

PITTSBURGH, Feb. 16, 1923.

Many sellers of steel liken present conditions in the steel industry to those obtaining in 1920, on the eve of an enormous advance in steel prices for early delivery. In that period the mills received a great deal of money, but afterward, with various losses and adjustments, it was found that they had retained very little. Accordingly the mills profess anxiety to avoid a repetition of the 1920 performance. Possibly there is an ambition, however, to repeat in a more moderate way the price advances but avoid entirely the subsequent losses.

Thus far, at any rate, steel prices have not been pegged, the market showing fully as much advancing tendency as in the past 3 or 4 weeks, and more advancing tendency than in the first 2 or 3 weeks of January.

Numerous Price Advances

Bars, shapes and plates, quotable for 2 or 3 weeks past at a range of 2.10@2.20c., are now practically at 2.20c. as minimum, with the usual exception of large lots for late delivery against construction jobs.

While most of the independent sheet mills remain out of the market, refusing to commit themselves on second quarter business, there is enough buying and selling to indicate that the market is likely to be established at advances of \$4 to \$7 a ton over prices lately ruling and at which the Steel Corporation has sold for second quarter, these prices being 2.50c. for blue annealed, 3.35c. for black and 4.35c. for galvanized. The spread between black and galvanized may increase from the recent 1c. to 1.15c.

The American Steel & Wire Co. has advanced its prices on nails and plain wire \$2 a ton, this being its first advance of the year on nails and its second on wire. Independents had previously been obtaining the higher prices. The market is now at 2.65c. for plain wire and \$2.80 for nails. Barb wire has also been advanced, also woven wire fence, the discount on which is now 69 per cent, in carload lots to jobbers.

Hoops and bands have been stiffening, the base price on heavy material advancing from 2.75c. to 2.90c., while light material, under 20 gage or 1-in. width, is 3.25@3.50c., base, against 3@3.25c. recently.

Semi-Finished Steel Higher

Recent transactions in billets, slabs and sheet bars appear to have cleaned up all steel available at the old price of \$38.50, and while recently some mills have been naming \$40 as their objective it seems doubtful now whether any steel could be bought at that figure. One seller of a large tonnage has had trouble in making scheduled deliveries and has been endeavoring to buy from other producers to apply on his obligation. The market in December was \$36.50, first quarter contracts being chiefly at that figure.

Latest developments suggest that possibly the decline in Connellsville coke is over, without prices reaching as low a level as expected. The theory has been that with the ending of winter the disappearance of buying for domestic consumption would cause further declines, but the new outlook is that increased consumptive demand will take up the expected slack. The change in basic conditions has been very decided. Not more than 2 months ago many steel producers were willing if not anxious to sell basic pig iron, as with their byproduct coke they could make it cheaper than merchant furnaces. The Republic Iron & Steel Co. was one of these, but now Republic has decided to blow in its Hannah furnace, a sort of reserve stack, and has bought coke, 500 tons a day to July 1, to take care of the stack, the company's byproduct coke covering only the Haselton stacks. The price paid is reported to be \$6.75. The market for spot furnace coke has declined 50c. in the week, being now quotable at \$7@\$7.25. This makes a total decline of \$2 since the end of December, but leaves the market 50c. higher than early in December, before the advance caused by buying of coke for domestic use.

Pig iron, expected by the majority of consumers for some time past to decline, now seems more likely to advance. Consumers must buy very soon now and an advance may easily be precipitated. The market is, indeed, a trifle stronger on the whole this week, as a result of a few transactions. Bessemer, formerly quotable at \$27.50@\$28 valley, is now firm at \$28 as minimum, while basic, quotable lately at \$25@\$26 valley, is now well established at \$26. Foundry remains at \$27@\$28. Freight to Pittsburgh is \$1.77.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

Vegetable Oils

Castor oil, No. 3, bbl.	lb	$ 12¼ – $ 13
Castor oil, AA, bbl.	lb	13¼ – 13½
Chinawood oil, bbl.	lb	18 – 18½
Coconut oil, Ceylon, bbl.	lb	.09½ – 9¾
Coconut oil, Cochin, bbl.	lb	.09¾ – 10
Corn oil, crude, bbl.	lb.	.11¼ – 11½
Cottonseed oil, crude (f.o.b. mill), tanks	lb	09¾ – 10
Summer yellow, bbl.	lb.	.12 – 12¼
Winter yellow, bbl.	lb	13 – 13¼
Linseed oil, raw, car lots, bbl.	gal	96 – 97
Raw, tank cars (dom.)	gal	92 – 93
Boiled, 5-bbl. lots (dom.)	gal	1 00 – 1 02
Olive oil, denatured, bbl.	gal.	1 00 – 1 15
Palm, Lagos, casks	lb	08 – 08¼
Palm kernel, bbl.	lb.	08¼ – 09
Peanut oil, crude, tanks (mill)	lb.	13 – 13½
Peanut oil, refined, bbl.	lb	16 – 16¼
Rapeseed oil, refined, bbl.	gal	85 – 86
Rapeseed oil, blown, bbl.	gal.	90 – 91
Soya bean (Manchurian), bbl.	lb.	.11½ – ..
Tank, f.o.b. Pacific coast	lb	.10 – ..

Fish Oils

Menhaden, light pressed, bbl.	gal	$0 60 – ..
White bleached, bbl.	gal	64 – 65
Blown, bbl.	gal.	68 – 69
Whale No. 1 crude, tanks, coast	lb	.06 – 06½

Dye & Tanning Materials

Divi-divi, bags	ton	$38 00 – $39 00
Fustic, sticks	ton	30 00 – 35 00
Fustic, chips, bags	lb	04 – 05
Logwood, sticks	ton	28 00 – 30 00
Logwood, chips, bags	lb.	02½ – .03½
Sumac, leaves, Sicily, bags	ton	65 00 –
Sumac, ground, bags	ton	55 00 – 60 00
Sumac, domestic, bags	ton	35 00 –
Tapioca flour, bags	lb.	.03¼ – 05

EXTRACTS

Archil, conc., bbl.	lb	$0 17 – $0 18
Chestnut, 25% tannin, tanks	lb.	.02 – 03
Divi-divi, 25% tannin, bbl.	lb	.04 – 05
Fustic, crystals, bbl.	lb	.20 – 22
Fustic, liquid, 42°, bbl.	lb	.08 – 09
Gambier, liq., 25% tannin, bbl.	lb	.08 – 09
Hematine crys., bbl.	lb.	.14 – 18
Hemlock, 25% tannin, bbl.	lb.	.04 – .05
Hypernic, solid, drums	lb	.24 – 26
Hypernic, liquid, 51°, bbl.	lb	.14 – .17
Logwood, crys., bbl.	lb.	.19 – 20
Logwood, liq., 51°, bbl.	lb.	.09 – 10
Quebracho, solid, 65% tannin, bbl.	lb.	.04¾ – 05
Sumac, dom., 51°, bbl.	lb.	.06½ – 07

Waxes

Bayberry, bbl.	lb	$0.28 – $0 30
Beeswax, refined, dark, bags	lb.	30 – 32
Beeswax, refined, light, bags	lb.	34 – 35
Beeswax, pure white, cases	lb	40 – 41
Candelilla, bags	lb.	.33 – 34
Carnauba, No. 1, bags	lb	38 – 40
No. 2, North Country, bags	lb	24 – 24½
No. 3, North Country, bags	lb.	17½ – 18½
Japan, cases	lb.	15 – 15½
Montan, crude, bags	lb.	.03½ – 04
Paraffine, crude, match, 105-110 m.p.	lb.	.04 – .04½
Crude, scale 124-126 m.p., bags	lb.	.02½ – 02¾
Ref., 118-120 m.p., bags	lb.	.03¼ – 03½
Ref., 125 m.p., bags	lb.	.03½ – .03¾
Ref., 128-130 m.p., bags	lb.	.04 – .04¼
Ref., 133-135 m.p., bags	lb.	.04½ – .04¾
Ref., 135-137 m.p., bags	lb.	05 – 05¼
Stearic acid, sgle pressed, bags	lb	10 – 10½
Double pressed, bags	lb	.10½ – 10¾
Triple pressed, bags	lb.	.11 – .11½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb.	$3 20 – $3 25
F.a.s. double bags	100 lb.	3 85 – 3 95
Blood, dried, bulk	unit	4 60 –
Bone, raw, 3 and 50, ground	ton	30 00 – 35.00
Fish scrap, dom., dried, wks.	unit	5.00 – 5.10
Nitrate of soda, bags	100 lb.	2.60 – 2.65
Tankage, high grade, f.o.b. Chicago	unit	4.70 – 4.80

Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	$3.50 – $4.00
Tennessee, 78-80%	ton	7.00 – 8.00
Potassium muriate, 80%, bags	ton	35 00 – 36.00
Potassium sulphate, bags	unit	1.00 – ....

Crude Rubber

Para—Upriver fine	lb.	$0 33 – $0 33½
Upriver coarse	lb	27 – 27½
Upriver caucho ball	lb	28½ – 29
Plantation—First latex crepe	lb	35 – 35¼
Ribbed smoked sheets	lb.	35 – .35¼
Brown crepe, thin, clean	lb.	31 – 32
Amber crepe No. 1	lb.	.31 – .32

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$450 00 – $550 00
Asbestos, shingle, f.o.b., Quebec	sh. ton	60 00 – 80 00
Asbestos, cement, f.o.b., Quebec	sh. ton	15 00 – 17 00
Barytes, grd., white, f.o.b. mills, bbl.	net ton	16 00 – 20 00
Barytes, grd., off-color, f.o.b. mills bulk	net ton	13 00 – 21 00
Barytes, floated, f.o.b. St. Louis, bbl.	net ton	24.00 – 28 00
Barytes, crude f.o.b. mines, bulk	net ton	8 50 – 9 00
Casein, bbl., tech.	lb.	.11 – 12
China clay (kaolin) crude, f.o.b. Ga.	net ton	7 00 – 9 00
Washed, f.o.b. Ga.	net ton	8 00 – 9 00
Powd., f.o.b. Ga.	net ton	13 00 – 20 00
Crude f.o.b. Va.	net ton	8 00 – 12 00
Ground, f.o.b. Va.	net ton	13 00 – 20 00
Imp., lump, bulk	net ton	15 00 – 20 00
Imp., powd.	net ton	45 00 – 50 00
Feldspar, No. 1 pottery	long ton	6 00 – 7 00
No. 2 pottery	long ton	5 00 – 5 50
No. 1 soap	long ton	7 00 – 7 50
No. 1 Canadian, f.o.b. mill	long ton	25 00 – 27 00
Graphite, Ceylon, lump, first quality, bbl.	lb.	06 – .06½
Ceylon, chip, bbl.	lb.	05 – .05½
High grade amorphous crude	ton	35 00 – 50 00
Gum arabic, amber, sorts, bags	lb.	15 – 16
Gum tragacanth, sorts, bags	lb.	50 – 60
No. 1, bags	lb.	1 75 – 1 80
Kieselguhr, f.o.b. Cal.	ton	40 00 – 42 00
F.o.b. N. Y.	ton	50 00 – 55 00
Magnesite, crude, f.o.b. Cal.	ton	14 00 – 15 00
Pumice stone, imp., casks	lb	03 – 05½
Dom., lump, bbl.	lb	05 – 05½
Dom., ground, bbl.	lb	06 – 07
Shellac, orange fine, bags	lb	82 – 83
Orange superfine, bags	lb	84 – 85
A. C. garnet, bags	lb	79 – 80
T. N., bags	lb	80 – 81
Silica, glass sand, f.o.b. Ind.	ton	2 00 – 2 50
Silica, sand blast, f.o.b. Ind.	ton	2 50 – 5 00
Silica, amorphous, 250 mesh, f.o.b. Ill.	ton	17 00 – 17 50
Silica, bldg. sand, f.o.b. Pa.	ton	2 00 – 2 75
Soapstone, coarse, f.o.b. Vt., bags	ton	7 00 – 8 00
Talc, 200 mesh, f.o.b., Vt., bags	ton	6 50 – 9 00
Talc, 200 mesh, f.o.b. Ga., bags	ton	7 00 – 9 00
Talc, 200 mesh, f.o.b. Los Angeles, bags	ton	16 00 – 20.00

Refractories

Bauxite brick, 56% Al_2O_3, f.o.b. Pittsburgh	ton	$45–50
Chrome brick, f.o.b. Eastern shipping points	ton	50–52
Chrome cement, 40-50% Cr_2O_3	ton	23–27
40-45% Cr_2O_3, sacks, f.o.b. Eastern shipping points	ton	23 00
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Ky. wks.	1,000	40–46
2nd quality, 9-in. shapes, f.o.b. wks.	1,000	36 41
Magnesite brick, 9-in. straight (f.o.b. wks.)	ton	65–68
9-in. arches, wedges and keys	ton	80 85
Scraps and splits	ton	85
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	48–50
Silica brick, 9 in. sizes, f.o.b. Birmingham district	1,000	48–50
F.o.b. Mt. Union, Pa.	1,000	42 44
Silicon carbide refract. brick, 9-in.	1,000	1,100.00

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N. Y.	ton	$200.00 – $225 00
Ferrochromium, per lb. of Cr, 6-8% C	lb.	.11½ – 11¾
4-6% C	lb.	.12 – 13
Ferromanganese, 78-82% Mn, Atlantic seabd. duty paid	gr. ton	105.00 – 107 50
Spiegeleisen, 19-21% Mn.	gr. ton	35.00 – 37.00
Ferromolybdenum, 50-60% Mo, per lb. Mo	lb.	1.90 – 2 15
Ferrosilicon, 10-15%	gr. ton	38.00 – 40 00
50%	gr. ton	80.00 – 85 00
75%	gr. ton	150.00 – 160.00
Ferrotungsten, 70-80%, per lb. of W	lb.	$0.90 – $0.95
Ferro-uranium, 35-50% of U, per lb. of U	lb.	6.00 – ....
Ferrovanadium, 30-40%, per lb. of V	lb.	3.50 – 4.00

Ores and Semi-finished Products

Bauxite, dom. crushed, dried, f.o.b. shipping points	ton	$6.50 – $8.75
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	ton	22 00 – 23 00
C.i.f. Atlantic seaboard	ton	18 50 – 19 00
Coke, fdry., f.o.b. ovens	ton	8 00 – 8 50
Coke, furnace, f.o.b. ovens	ton	7 00 – 7.50
Fluorspar, gravel, f.o.b. mines, New Mexico	ton	17 50 – ....
Fluorspar, No. 2 Lump—Ky. & Ill. mines	ton	25 00 – ....
Ilmenite, 52% TiO_2	lb	.01½ – .01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.33 – ....
Manganese ore, chemical (MnO_2)	ton	75.00 – 80.00
Molybdenite, 85% MoS_2, per lb. MoS_2, N. Y.	lb.	.65 – .70
Monazite, per unit of ThO_2, c.i.f., Atl. seaport	lb.	.06 – .08
Pyrites, Span., fines, c.i.f. Atl. seaport	unit	.11½ – .12
Pyrites, Span., furnace size, c.i.f. Atl. seaport	unit	.11½ – .12
Pyrites, dom. fines, f.o.b. mines, Ga.	unit	.12
Rutile, 95% TiO_2	lb.	.12 – ....
Tungsten, scheelite, 60% WO_3 and over, per unit WO_3	unit	8.00 – 8.50
Tungsten, wolframite, 60% WO_3 and over, per unit WO_3	unit	7.50 – 8.00
Uranium ore (carnotite) per lb. of U_3O_8	lb	3.50 – 3.75
Uranium oxide, 96% per lb. U_3O_8	lb	2 25 – 2 50
Vanadium pentoxide, 99%	lb.	12 00 – 14.00
Vanadium ore, per lb. V_2O_5	lb	1.00 – .....
Zircon, washed, iron free, f.o.b. Pablo, Fla.	lb	.04½ – .13

Non-Ferrous Materials

	Cents per Lb.
Copper, electrolytic	15 25
Aluminum, 98 to 99%	23 00
Antimony, wholesale, Chinese and Japanese	7 15-7.50
Nickel, virgin metal	25 00 27.00
Nickel, ingot and shot	29 00
Monel metal, shot and blocks	32 00
Monel metal, ingots	38 00
Monel metal, sheet bars	45 00
Tin, 5-ton lots, Straits	41 00
Lead, New York, spot	8 05

No. 1 yellow brass turnings	6 30@ 6 50
Zinc	3.50@ 4.00

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	$3 29	$3.14
Soft steel bars	3.19	3.04
Soft steel bar shapes	3.19	3.04
Soft steel bands	3.29	3.19
Plates, ¼ to 1 in. thick	3.29	3.14

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

CEMENT—The Petoskey Portland Cement Co., Petoskey, Mich., is operating at full capacity with regular working force. It is purposed to create all possible reserves for spring distribution, totaling approximately 250,000 bbl., as now estimated.

Cement mills in the vicinity of Nazareth, Pa., are running at maximum and have sufficient orders on hand to continue on this basis until well into next fall.

The Bessemer Limestone & Cement Co., Bessemer, Pa., is planning for the early resumption of activities at its cement mill, closed down on Feb. 1 for necessary machinery repairs. The plant was completed a little over a year ago and has been in steady operation since that time. It is proposed to perfect arrangements for increased production.

All cement mills in the vicinity of Coplay, Pa., are running full, and purpose to maintain this basis of production for an indefinite period.

CERAMIC—The O. Zimbal Brick Co., Sheboygan, Wis., is perfecting plans for immediate increased production at its plant.

The Southern Brick & Tile Co., Louisville, Ky., has resumed production at its plant after a brief curtailment. It is planned to develop maximum output at an early date.

The Coral Ridge Clay Products Co., Louisville, Ky., manufacturer of brick and tile products, is operating at full capacity, with output about equally divided between brick and tile. It is purposed to continue operations throughout the winter.

Sanitary ware plants at Philadelphia, Pa., and vicinity are running on a curtailed schedule owing to the unsettled strike of the operative sanitary potters. A number of potteries are breaking in new men and expect to advance production at an early date.

The Tri-City Brick Co., Carbon Cliff, Ill., is operating at full capacity and has plans maturing for extensions to provide for early increase in output. Additions will be made in the working force.

LEATHER—The Griess-Pfleger Tanning Co., Waukegan, Ill., is running under good capacity at its local tannery, producing calfskins, splits and kindred specialties. The company also operates a tannery in Chicago, and is maintaining regular production at this point.

The Mississippi Valley Tanning Co., St. Louis, Mo., is maintaining regular production at its local tannery, giving employment to a normal working force. Operations are devoted to black glazed kid.

OIL—The Sinclair Oil Corp., New York, is pushing construction on its new oil refinery at Trainer, near Marcus Hook, Pa., and the present building force of 500 men will be increased to 1,000 men at an early date. Foundations are being laid for 24 stills, each with capacity of 1,000 bbl. When completed, the plant will give employment to approximately 600 workers, and will represent an investment of close to $1,000,000.

The American Cotton Oil Co., 65 Broadway, New York, has closed a number of its cottonseed crushing mills for the season. Several plants will remain shut down permanently, while operations at the others will be resumed as soon as conditions warrant. The company expects to maintain its cottonseed oil business at the present status, with possible increase in the future; it will not abandon this branch of operation, as currently reported.

The Producers' & Refiners' Corp., California Bldg., Denver, Colo., is planning for an early increase in production at its refining plants in Wyoming, advancing from 10,000 to 15,000 bbl. per day. Before the close of the year, it is expected to develop a capacity of 20,000 bbl. per day.

Employees of the Vacuum Oil Co., Bayonne, N. J., have asked an increase in wages aggregating 12 per cent. The request will be considered at an early meeting of the board of directors. Employment is now being given to about 600 operatives.

Workers at the refining plant of the Tidewater Oil Co., Bayonne, N. J., has been granted a wage advance of about 2 per cent. The men recently asked for an increase approximating 12 per cent. About 2,000 employees are affected.

PAPER—The Fort William Paper Co., Ltd., Fort William, Ont., is planning for an early increase in production at its new newsprint mill, recently placed in service. The present output approximates 75 tons daily and this will be advanced to a continuous run of 150 tons per day some time in March.

The Plainfield Paper Co., recently organized to take over and succeed the Childs Paper Co., Childsdale, near Rockford, Mich., is planning for early operations at the local mill, giving employment to a regular working force. Burke M. Baxter has been elected president.

The River Raisin Paper Co., Monroe, Mich., is operating on a full capacity schedule, giving employment to a regular working force, and expects to continue on this basis for an indefinite period. The bulk of production is devoted to corrugated and fiber paper specialties.

Paper mills in the state of Washington devoted to newsprint are all running at maximum production, with advance orders to insure the continuance of this schedule for more than 12 months to come.

IRON AND STEEL—The Alabama Co., Birmingham, Ala., is arranging for the immediate blowing in of its blast furnace at Gadsden, Ala., for pig iron production.

The Penn-Seaboard Steel Corp., Philadelphia, Pa., is operating at about 55 per cent of normal plant capacity, and purposes to advance this schedule at an early date.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., is completing repairs to its Oxmoor blast furnace, and plans to have the unit ready for service by the close of the month. The company is operating its four furnaces at Bessemer, Ala., for pig-iron production while six furnaces at Ensley and one furnace at Birmingham are running on basic iron. The company is said to have heavy orders on hand.

The Youngstown Sheet & Tube Co., Youngstown, O., has blown in its second blast furnace at Hubbard, near Sharon, Pa.

The blast furnace at the lower works of the Glasgow Iron Co., Pottstown, Pa., idle for a number of years, has been sold to other interests and will be dismantled at an early date.

Eight of eleven furnaces at the Edgar Thomson Works of the Carnegie Steel Co., North Braddock, Pa., are now in operation. Furnace H, which has been idle since March, 1921, has just been blown in.

MISCELLANEOUS—The Interstate Glass Co., Huntington, W. Va., manufacturer of window glass, has resumed operations at its plant after a shutdown for more than a year. It is expected to develop maximum capacity at an early date, giving employment to about 300 persons.

The Cadillac Lumber & Chemical Co., Sault Ste. Marie, Mich., is pushing construction on its new local plant and plans to inaugurate production late in April or early in May. Two more buildings will be erected and equipped.

Paint and varnish manufacturers in the Philadelphia, Pa., district are operating from 75 to 100 per cent capacity, with full working forces.

The International Nickel Co., New York, is operating in certain departments at its new plant at Huntington, W. Va., and expects to increase production gradually until the works are running full. The plant represents an investment of close to $3,000,000.

The Tennessee Copper & Chemical Co., 61 Broadway, New York, is operating at full capacity at its new sulphate plant, and will continue on this basis for an indefinite period. It is said that the entire output for the present year has been sold.

Construction and Operation

Alabama

ANNISTON—The Independent Soil Pipe Co., has awarded a contract to the Ogletree Construction Co., Anniston, for the erection of a 1-story addition to its foundry, 70x108 ft., comprising the former works of the Ajax Foundry Co., lately acquired. It will be used for the production of cast-iron pipe. R. B. Carr is secretary.

BESSEMER—The Imperial Pipe Co., manufacturer of cast-iron pipe, will make extensions and improvements in its plant to increase production about 50 per cent. Facilities will be provided for the employment of 50 additional men.

BIRMINGHAM—The United States Cast Iron Pipe & Foundry Co., 71 Broadway, New York, will soon commence enlargements in its local plant for considerable increase in capacity. Considerable new machinery will be installed, including equipment for the de Lavaud process of cast-iron pipe production. The company is also planning for extensions in its foundry at Burlington, N. J., for the installation of similar machinery.

California

SAN FRANCISCO—The Los Angeles Soap Co., 633 1st St., Los Angeles, manufacturer of soaps, washing powders, etc., has awarded a contract to H. N. McClure, San Francisco, for excavation for its proposed new plant at 2nd and Brannan Sts., to be 2-story and basement, estimated to cost $80,000. Work will be placed under way at once. Other contracts for erection will be let immediately. W. H. Crim, Jr., 425 Kearny St., San Francisco, is architect.

PITTSBURG—The Columbia Steel Corp., San Francisco, has awarded a contract to the Union Construction Co., Key Route Fill, Oakland, for the erection of five new buildings at its local plant, estimated to cost in excess of $150,000, inclusive of equipment. Work will be placed in progress at once.

Colorado

DENVER—The Producers' & Refiners' Corp., California Bldg., is planning for the immediate construction of a large oil-refining plant in the vicinity of its present works at Greenville, Wyo. A new pipe line, pumping plants and other structures will be built. A stock issue of $7,500,000 has been arranged, a portion of the proceeds to be used for the expansion.

Connecticut

BRIDGEPORT—Jenkins Brothers, Inc., 80 White St., New York, will install a new foundry in connection with additions to its local plant for the manufacture of valves and other kindred engineering products, to be equipped for cast-steel and cast-iron production heretofore secured from outside plants. The extensions, with equipment, will cost approximately $250,000. The company is arranging for a bond issue of $1,000,000, the expansion appropriation to be taken from this fund. Lockwood Greene & Co., 101 Park Ave., New York, are engineers. Bids will be called at once.

Delaware

NEW CASTLE—The Wilmington Fibre Specialty Co. has acquired the fiber plant of the Johns-Manville Co., Lockport, N. Y., and will remove the equipment to its local plant. Enlargements will be made in the New Castle works to accommodate the expansion, including the installation of fiber-making machinery, rolling machines and auxiliary equipment. The work is estimated to cost about $190,000. John W. Morris is president.

Florida

TAMPA—The Tampa Gas Co. is planning for extensions and improvements in its artificial gas plant to cost about $200,000, including equipment.

JACKSONVILLE—William Nusbaum has arranged for the establishment of a local plant for the production of sisal fiber products. It will be operated under the name of the Cordova Hat Co.

Georgia

VALDOSTA—The Walker-Wood Products Co., manufacturer of turpentine, etc., has

plans under way for extensions in its plant, to include the installation of additional equipment.

SYLVESTER—The Tomlinson-Haddock Co., Albany, Ga., has acquired a local tract of land and plans for the installation of a local plant for the production of turpentine. The initial still capacity will be extended at an early date.

Idaho

PRIEST RIVER—The Spokane Soap Products Co., Spokane, Wash., manufacturer of soaps, washing powders, etc., has concluded negotiations for a local site and plans for the early erection of a new plant.

Illinois

OTTAWA—The National Plate Glass Co., General Motors Bldg., Detroit, Mich., affiliated with the Fisher Body Co., same address, manufacturer of automobile bodies, has acquired a tract of land of about 200 acres at Ottawa, adjoining the plant of the Federal Plate Glass Co., a subsidiary organization. Plans are under way for the erection of a new plant, to be operated under the Federal name, with capacity of close to 15,000,000 sq.ft. of polished glass per annum, practically doubling the present works capacity. The buildings with machinery are estimated to cost approximately $5,000,000. L. P. Fisher is vice-president of the National company.

MT. VERNON—The Mt. Vernon Car Mfg. Co. has preliminary plans in progress for the rebuilding of its foundry, recently destroyed by fire. The new structure will cost approximately $25,000. Neiler, Rich & Co., 431 South Dearborn St., Chicago, are engineers.

CHICAGO—L. A. Malchor, formerly connected with the Oxweld Acetylene Co., will commence the immediate erection of a new 1-story welding plant at 2613-17 State St., estimated to cost approximately $25,000, including equipment.

CHICAGO—The Detroit Copper & Brass Rolling Mills, 111 North Jefferson St., have purchased property at Washington Blvd. and Ada St., 50x170 ft., for a consideration of about $42,000. The site will be used for the erection of a new plant in the near future. Construction will be deferred for several months, owing to existing property leases.

Indiana

INDIANAPOLIS—The Indianapolis Terra Cotta Co., 1241 Consolidated Bldg., is considering plans for the erection of a new plant at Roosevelt and Olney Sts. George H. Lacy is general manager.

INDIANAPOLIS—The National Malleable Castings Co. has filed plans for the erection of an addition to its plant at Holmes and West Michigan Sts.

SEYMOUR—The Silverstone Stucco & Plaster Products Co., 220 Indiana Pythian Bldg., Indianapolis, is taking bids on a general contract for the erection of its proposed new local plant, the first unit to be 1-story, 50x96 ft. Merritt, Harrison & Turnock, 500 Board of Trade Bldg., Indianapolis, are architects. L. M. Briggs is secretary.

Kansas

WICHITA—The Derby Refining Co. is planning for additions in its local oil-refining plant to increase the present output about one-third. The rated capacity is 5,000 bbl. per day. The work is estimated to cost approximately $300,000, including machinery.

LEAVENWORTH—The Bonner Portland Cement Co. is having plans prepared for extensions in its plant to cost approximately $1,500,000, including machinery. Headquarters of the company are in the Victor Bldg., Kansas City, Mo.

Kentucky

LOUISVILLE—The Standard Sanitary Mfg. Co., Bessemer Bldg., Pittsburgh, Pa., manufacturer of sanitary ware, has tentative plans under consideration for the erection of a new addition to its local pottery on Shipp Ave., to be 2-story and basement, 125x500 ft. The company recently completed an extension to the works.

Maryland

BALTIMORE—The United States Asphalt Refining Co., Fairfield Rd., Wagner's Point, will install a number of new steel tanks and auxiliary equipment at its plant.

NORTH EAST—The North East Porcelain Co., recently organized, has acquired a local works, previously used for porcelain manufacture, and will establish a new plant. The structure will be remodeled, and extensions and improvements made, including the installation of new machinery. It is expected to have the plant ready for service early in April. E. Kirk Brown, Charles A. Ferguson and J. Wesley McAllister head the company.

BALTIMORE—The Standard Oil Co. has completed plans for the installation of additional steel tanks and auxiliary equipment at its plant at 1st Ave. and 3rd St., to cost about $30,000.

Massachusetts

NEW BEDFORD—The New Bedford Gas & Edison Light Co. will install experimental machinery at its artificial gas works for the manufacture of gas from crude oil. The equipment will replace the retorts heretofore used. It is expected to install additional apparatus of the character noted at a later date.

Michigan

BATTLE CREEK—Philip Ruxton, Inc., 220 West 42nd St., New York, manufacturer of printing inks, has acquired the local plant of the F. A. Rigler Ink Co., and plans for the early erection of a large addition to the plant to double, approximately, the present capacity.

DETROIT—The Unique Brass Mfg. Co., 123 Military Ave., is planning for the rebuilding of the portion of its plant, destroyed by fire, Feb. 5. An official estimate of loss has not been announced.

MONROE—The Monroe Paper Co. has awarded a contract to August Radtke, 528 South Smith Ave., for the rebuilding of the portion of its plant recently destroyed by fire, estimated to cost about $50,000. Leonard Mitchell is manager.

DETROIT—The Schroeder Paint & Glass Co., 119 Cadillac Sq., has construction under way on a new 4-story plant at 12th and Antoinette Sts., 125x195 ft., estimated to cost approximately $300,000, including equipment.

Missouri

WEST PLAINS—The National Rendering Co., 5th St. and the Kaw River, is completing plans and will soon commence the erection of a new local plant for reduction service, with departments for the manufacture of tallow and kindred products, estimated to cost about $25,000. W. R. Ross is president.

Montana

LEWISTOWN—The Gordon Campbell-Kelvin Syndicate is planning for the organization of a subsidiary company, with capital of $1,000,000, to construct and operate an oil refinery and topping plant. A site for the proposed refining plant is being selected in the vicinity of Seattle, Wash., while the new topping plant will be situated near Spokane. A pipe line will be constructed to the Kelvin oilfields of the parent organization. Gordon Campbell is head of the company.

New Hampshire

PORTSMOUTH—The Bureau of Supplies and Accounts, Navy Department, will take bids until Feb. 27 for furnishing and installing an annealing furnace at the local navy yard.

New Jersey

ROOSEVELT—Fire, Feb. 3, destroyed a portion of the local plant of the Armour Fertilizer Works, with loss estimated at about $75,000, including equipment. It is planned to rebuild. Headquarters of the company are at 209 West Jackson Blvd., Chicago, Ill.

BAYONNE—The Vacuum Oil Co., foot of East 22nd St., will erect a new building at its local refining plant to cost about $110,000. Headquarters of the company are at 61 Broadway, New York.

BERKELEY HEIGHTS—The J. H. Stone Corp., manufacturer of cork insulation products, has tentative plans under consideration for the rebuilding of the portion of its local plant destroyed by fire, Feb. 6, with loss estimated at close to $150,000, including machinery. The company also operates a plant at Port Colburn, Ont.

New York

LONG ISLAND CITY—The Atlas Novelty Co., 722 East 11th St., New York, manufacturer of celluloid and composition products, has acquired property at Hancock St. and Freeman Ave., Long Island City, 38x112 ft., as a site for the erection of a new plant. Plans will be prepared at an early date.

POTSDAM—Hollis W. Martin, Norwood, N. Y., is organizing a company to construct and operate a paper mill on site recently acquired on the Requette Rd. T. L. Tomlines, City Bank Bldg., Syracuse, engineer, has been commissioned to prepare plans for a 1-story plant, estimated to cost approximately $100,000, with machinery. It is expected to call for bids at an early date.

WATERFORD—The Little Falls Fibre Co., Little Falls, is planning for the rebuilding of the portion of its local plant destroyed by fire, Feb. 9, with loss approximating $50,000, including equipment.

North Carolina

WILMINGTON—The Seminole Phosphate Co., Goldsboro, N. C., has leased a building at the foot of Hanover St., Wilmington, for the establishment of a new plant for the manufacture of fertilizer products.

Ohio

RITTMAN—The Ohio Box Board Co., Wadsworth, O., is completing plans and will soon commence the erection of a new plant at Rittman, comprising a 1-story building, 110x800 ft., estimated to cost about $200,000, including equipment for the manufacture of cardboard and boxboard products. Christian, Schwarzenberg & Gaede, Euclid Bldg., Cleveland, are engineers. E. J. Young is president.

LOWELLVILLE—The Republic Iron & Steel Co., Youngstown, O., has plans under way for the construction of a new byproducts coke plant addition, estimated to cost approximately $5,000,000. The Koppers Co., Union Arcade, Pittsburgh, Pa., is engineer and contractor.

Oklahoma

OKLAHOMA CITY—The Dead Shot Chemical Co., 103 West Noble St., has preliminary plans under consideration for the rebuilding of the portion of its plant destroyed by fire, Feb. 3, with loss approximating $75,000, including equipment and stock.

PONCA CITY—The Marland Refining Co. has tentative plans in progress for the construction of an addition to its local oil-refining plant, to increase the capacity from 12,000 to 15,000 bbl. per day. E. W. Marland is president.

Oregon

ASTORIA—The Union Oil Co., Mills Bldg., San Francisco, Calif., is planning for the construction of a new refining and distributing plant on local site, estimated to cost $500,000, including equipment.

Pennsylvania

NEW CASTLE—The United States Steel Corp., Pittsburgh, Pa., has plans under way for additions and improvements in its local Carnegie works, including power and other equipment installation, estimated to cost in excess of $500,000.

ALLENTOWN—The Lehigh Soap Works, Water St., has acquired factory property at Hanover Ave. and Sherman St., and will remodel the structure for a new plant. The present works will be removed to the new location. Enoch Painter heads the company.

YORK HAVEN—Fire, Feb. 8, destroyed a portion of the plant of the York Haven Paper Co., with loss estimated at about $50,000. It is planned to rebuild.

PHILADELPHIA—The C. H. Boley Co., 3726 North Randolph St., manufacturer of chemical products, has awarded a contract to Charles H. Schaefer, Otis Bldg., for the erection of a 1-story plant addition, estimated to cost about $15,000.

South Carolina

HARTSVILLE—T. H. Coker, Hartsville, is planning for the installation of a local clay-grinding plant for commercial kaolin production. Inquiries are being made for equipment for grinding 80 per cent fine, through a 100-mesh screen.

Tennessee

CHATTANOOGA—The Dixie Portland Cement Co. is arranging a program for extensions and improvements at its plant to cost about $200,000, including additional equipment.

Texas

TEXAS CITY—The Texas Sugar Refining Co., lately formed with a capital of $5,500,000, has been organized with Alexander Smith, of Peabody, Houghteling & Co bankers, 366 Madison Ave., New York, as president. Plans for the proposed local refinery have been extended from a proposed investment of $100,000 to one of close to $1,000,000, including machinery. The works will consist of a number of buildings for an initial capacity of about 1,000,000 lb. of refined sugar per day, which will be increased in the future It is purposed to have the first units ready for service before the close of the present year, giving employment to about 400 operatives.

West Virginia

PARKERSBURG—The General Porcelain Co has tentative plans under consideration for the establishment of a new branch plant on site to be selected on the Pacific Coast It is understood that preference will be given to a location in the vicinity of Portland, Ore.

CHESTER—The Cord Tire Co. has plans in progress for the erection of an addition to its plant to increase the output from 650 to 3,000 tires a day. It is estimated to cost in excess of $125,000, with machinery

New Companies

THE KESITE CHEMICAL CO., New York, N. Y., care of D. K. Shappiro, 276 5th Ave, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are H Johnson, N. Kessel and W T. Sandall

THE SUSSEX CHEMICAL PRODUCTS Co, 169 Sussex St, Jersey City, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and kindred products. The incorporators are Louis S Hirsch, Paul B. Ducas and Edward Dreyfus.

THE HOLYOKE BRICK Co, Holyoke, Mass, has been incorporated with a capital of $100,000, to manufacture brick, tile and other burned clay products. Patrick J Kennedy, Jr. is president; and Henry H Parsons, 69 Locust St, Holyoke treasurer

THE MIDWEST SUGAR REFINING Co, 326 Madison St, Chicago, Ill., has been incorporated with a capital of $1,000,000, to construct and operate sugar-refining plants. The incorporators are John W Davis, Arthur E. Dike and Ira H. McKinney.

THE AGO CHEMICAL CO., 1301 Fidelity Bldg, Baltimore, Md., has been incorporated with a capital of $150,000, to manufacture chemicals, soaps and kindred products The incorporators are A J. Sherman, E. A. Hummer and J. C Hamburger

THE OPALESCENT PAPER Co., Providence, R I., has been incorporated with a capital of $150,000, to manufacture paper products The incorporators are William H. Hamlyn, Sr. and Jr, both of Providence; and Harold C. Pearl

THE H R JEFFERDS Co., New York, N Y, care of J I. Perry, 84 William St., representative, has been incorporated with a capital of $52,700, to manufacture chemicals and rubber products. The incorporators are J. C Treadwell and H R. Jefferds.

THE CHEMICAL ENGINEERING Co Cambridge, Mass, has been incorporated with a capital of 200 shares of stock, no par value, to manufacture chemical specialties and operate as chemical engineers. Porter O. Robinson is president; and J. Denison Kenyon, 8 Midland St, Worcester, Mass, treasurer. The last noted represents the company.

LEHMAN BROTHERS, INC, Jersey City N J., has been incorporated with a capital of $50,000, to manufacture paints, oils, etc The incorporators are David I. Goldstein, Hart and Earl Lehman, 22 Halladay St., Jersey City. The last noted represents the company

THE ECONOMY OIL Co., Clarendon, Va, has been incorporated with a capital of $200,000, to manufacture petroleum products The incorporators are John Sallen and R. R. Allen, both of Clarendon

THE PRISM SOAP & CHEMICAL Co, New York, N. Y., care of Samuel Falk, 291 Broadway, representative, has been incorporated with a capital of $50,000, to manufacture chemicals, soaps and kindred products The incorporators are J. Jordan, F. Mancuso and F. C. Battistella.

THE TEASDALE GLUE Co., Grand Rapids, Mich., has been incorporated with a capital of $20,000, to manufacture glue, paste and kindred specialties. The incorporators are John H. Nind, Jr, E. U. Kettle and Clyde H. Teasdale, 1517 Robinson Rd., Grand Rapids.

THE SPONGE RUBBER PRODUCTS Co., New Haven, Conn., has been incorporated with a capital of $50,000, to manufacture rubber specialties The incorporators are Frederick M. Daley, William R. Todd and Lowell Smith, all of Naugatuck, Conn.

THE R. D. BURCHARD CHEMICAL Co, St. Louis, Mo, has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts The incorporators are R. D. Burchard, J. W. Walsh and Benjamin M. Carriso, all of St. Louis.

THE UNITED STATES TURPENTINE Co, care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, with capital of $5,000,000, to manufacture turpentine and affiliated products.

THE FRIEDLANDER SUPPLY CORP., 1212 Roosevelt Blvd., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture chemicals, waxes, colors, etc. The incorporators are Samuel J. Friedlander, Charles K. Schwartz and Herbert Friedlander.

THE MASTER PRODUCTS Co, Newark, N. J., has been incorporated with a capital of $75,000, to manufacture polishes for wood and metal work. The incorporators are Lorenzo A. Crowley and James Hilton, 99 Peshine Ave., Newark The last noted represents the company.

THE DADE CITY BRICK Co., Dade City, Fla, has been incorporated with a capital of $10,000, to manufacture brick, tile and other ceramic products The incorporators are F M Ackerman, S H Ackerman and D D Faulkner, all of Dade City.

THE MCLAUGHLIN PAPER Co, San Francisco, Calif, has been incorporated with a capital of $100,000, to manufacture paper products. The incorporators are F M McAuliffe, Samuel B. Stevens and Jerome B. White, Nevada Bank Bldg., San Francisco. The last noted represents the company.

THE SINCLAIR & CARROLL Co, New York, N Y, has been incorporated with a capital of $100,000, to manufacture printing inks and kindred products The incorporators are R Bennett, P. G Brennan and W. J. Ryan The company is represented by Wing & Russell, 14 Wall St. New York

THE ARTHUR DOVE Co, 5850 Forsyth St., Detroit, Mich, has been incorporated with a capital of $50,000, to manufacture paints and enamels for industrial service. The incorporators are Fred W. Grundman, Henry P Zapp and Arthur Dove, 3017 East Grand Blvd., Detroit.

THE L. H. HAMEL LEATHER Co., Haverhill, Mass, has been incorporated with a capital of $50,000, to operate a local leather-tanning plant. Arthur A. Hamel is president, and Louis H. Hamel, 49 Lexington Ave, Bradford, Mass., treasurer. The last noted represents the company

THE PATAPSCO OIL & GREASE Co., 109-11 Chesapeake St., Baltimore, Md., has been incorporated with a capital of $50,000, to manufacture oils, greases and compounds. The incorporators are John and David L. Ryan, and Harry E. Parkhurst.

THE GENERAL FOUNDRY Co., Fort Worth, Tex, has been incorporated with a capital of $25,000, to manufacture iron, steel and other metal castings. The incorporators are B N. Wadley, R. A. and F. M. Stewart, all of Fort Worth.

THORNE & Co, INC., Elizabeth, N. J., care of Albert Ehinger, 658 Van Buren Ave, Elizabeth, representative, has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are S. Reinhart, Irving Eiseman and E. Horowitz

Capital Increases, etc.

THE VICTORIA PAPER MILLS Co., Fulton, N Y, has filed notice of increase in capital from $100,000 to $250,000 for general expansion

THE STERLING BRICK Co, 5201 12th St., Detroit, Mich., has arranged for an increase in capital from $25,000 to $75,000.

THE JOHNSON OIL REFINING Co. 208 South LaSalle St., Chicago, Ill., has arranged for an increase in capital from $2,000,000 to $3,000,000 for expansion.

PRICE BROTHERS & Co., Quebec, Can., operating pulp and paper mills, is disposing of a bond issue of $10,000,000, a portion of the proceeds to be used for expansion and general financing.

THE GORDON PETROLEUM Co., Eastland, Tex., has arranged for an increase in capital from $150,000 to $1,000,000 for proposed expansion.

THE HUDSON BRASS WORKS, INC., 16 Nassau St., Brooklyn, N. Y., has filed notice of increase in capital from $150,000 to $250,000 for expansion.

THE GEORGETOWN OIL Co., Georgetown, Del., has arranged for a change of name to the Union Oil Corp., at the same time increasing its capital from $50,000 to $300,000

THE INLAND ENGINEERING Co, Chicago, Ill., has filed notice of change of name to the Standard Alloy Steel Co.

THE CONNECTICUT CHEMICAL Co., Hartford, Conn., has filed notice of dissolution under state laws. William H. Barnum, 111 Broadway, New York, is president and represents the company.

THE COLUMBIA STEEL CORP., San Francisco, Calif., with plant at Pittsburgh, Cal., a Delaware corporation, has arranged for an increase in capital from $20,000,000 to $110,000,000 for general expansion.

THE STANDARD SANITARY MFG. Co., Bessemer Bldg., Pittsburgh, Pa., manufacturer of enameled iron and clay products, a New Jersey corporation, has filed notice of increase in capital from $20,000,000 to $30,000,000 for general expansion.

THE OLBURY ELECTRO CHEMICAL Co., Harrison, N. Y., has filed notice of decrease in capital from $1,500,000 to $1,000,000.

THE GASKILL CHEMICAL CORP., 157 Spencer St., Brooklyn, N. Y., has filed notice of increase in capital to $65,000.

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va., May 7 to 9

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O., April 28 to May 4.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS is holding its annual meeting in New York City this week.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 10 and 11 at the House of the Institution of Civil Engineers, London, S W. 1.

NATIONAL FOREIGN TRADE COUNCIL has postponed its annual conference from April 25, 26 and 27, to May 2, 3 and 4. It will be held in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Volume 28 New York, February 28, 1923 Number 9

The Outlook For Rubber

WHETHER rubber shall soar to exorbitantly high prices or maintain a stable market depends principally on the decision of the East Indian Government and the British planters either to maintain or to remove the present restriction on production. The United States is in a peculiar economic position with respect to rubber. Our industries consume about 75 per cent of the world's output, but British planters in the East Indies control 75 per cent of the world's production. Consequently unless there is close accord between these two great factors of supply and demand, it is quite evident that the rubber market will be upset to the detriment of producer as well as consumer. In this industry, as in all others, stabilization is the great desideratum.

From the point of view of the United States the present obstacle to stabilization is legislation in the East Indies restricting the output of rubber to 60 per cent of plantation capacity. It is true that the law makes provision for increases in production by increments of 10 per cent whenever certain prices are maintained for 90-day periods, thus making possible 100 per cent production in 12 months. But the fatal objection to this plan is that our capacity to consume rubber is increasing at such a rate that before these restrictive measures can be carried out our demand will entirely overtake the productive capacity of the planters. In fact the world demand for rubber probably warrants 100 per cent production at the present time.

With a view to bringing about a better understanding, representatives of the British plantation owners have recently visited this country and, it is believed, have been duly impressed with our capacity to consume rubber. We understand they have returned prepared to recommend that the restrictive measures be removed immediately in order to avoid a shortage and consequent high prices. They realize that a stabilized market at a fair average price, year in and year out, will be best for all concerned.

In the meantime the Department of Commerce evidently believes that it is just as well to show a lively interest in the possibility of stimulating the production of rubber elsewhere than in the East Indies. It is true that conditions there are almost ideal: cheap labor, healthy surroundings and liberal land laws, coupled with a cultivated skill in the production of plantation rubber. Nevertheless there is no reason why equally favorable conditions cannot be found or created elsewhere for the purpose of bringing competition into the plantation rubber industry. This explains the request of the Secretary of Commerce for a special appropriation of $500,000 to investigate the possibility of rubber production in other tropical countries, including the Philippine Islands. Probably too much has been made of the prospect of raising rubber in the Philippines, because economic conditions there are not favorable to the development of a large industry. The land laws restrict ownership of areas to 2,500 acres or less, and labor is expensive. But more important perhaps than either of these factors is the question of the future political destiny of the islands. It is doubtful if American capital would be freely invested in rubber developments in the Philippines unless there was assurance of continued United States control.

But there are other tropical countries closer at hand that would be more suitable sources of rubber as far as the United States is concerned. Brazil, for example, might prove satisfactory if the land laws were liberalized and health conditions improved. Our Department of Agriculture thinks that there is even a possibility that rubber may yet be produced in the temperate zone; but this is a remote contingency—something that may come to pass in 25 or 30 years.

Any measures looking to the development of new sources of plantation rubber cannot be of assistance in the present crisis. Under the most favorable conditions new plantations cannot come into production for 7 years, and it would probably be a decade before their product would be a material factor in the market. The immediate hope of an adequate supply at a reasonable price is intelligent action by the British with respect to their present restrictions. If our laws permitted combinations of American firms in import trade, it would be possible to control such markets as rubber and other commodities of which we are the world's largest consumers but for which we are dependent on some other nation for our supply. Since this is impossible, the most hopeful prospect lies in a friendly understanding between the producing and consuming industries.

Standards for Heavy Chemicals

STANDARD specifications for heavy chemicals have been discussed from time to time, but no one seems to have made any very striking progress on the subject. For some reason the manufacturers have been unwilling to take the initiative in drafting such specifications. And the users have been scattered through so many industries and have been so poorly organized as to preclude any effective action on their part. However, a movement that is steadily gaining ground promises to remedy this defect.

The Federal Specifications Board of the United States is constituted of representatives of various government departments interested in purchases. Sub-committees of this board are appointed to draft specifications for the various commodities that the government buys in quantities. One of these commodities now receiving attention is sulphuric acid for storage batteries. No sub-committee has as yet been appointed, but it is proposed

that there shall be such a committee to consider the specifications now being drafted for this purpose by the Bureau of Standards. Certainly some definite specifications can be expected during the next few months.

Sulphuric acid is produced in many qualities and sold under many trade designations. One of the principal uses of sulphuric acid which demands a staple and uniform product is the storage battery. It is estimated that from 50,000,000 to 100,000,000 pounds of sulphuric acid goes into batteries every year and that there is no particular reason why there should not be a uniform requirement as to the quality of this acid. The Bureau of Standards proposes to find out what can reasonably be required and what is essential for proper service from this material.

The specifications which the bureau proposes will doubtless find wide application and it is almost certain that they will eventually become the official requirement for all acid purchased by the government. When that is done, hundreds, if not thousands, of other purchasers are likely to copy the government requirements. This, therefore, is a movement which the manufacturers of acid cannot ignore. It is a movement which is more than likely to determine what quality of acid they will have to make sooner or later in order to supply the demand. It is another case in which the manufacturers will do well to take steps for active co-operation with the government, in order that the most effective and the most workable requirements may be fixed to the mutual advantage of producer and user. It is not too much to hope that such co-operation can be arranged at once for this material. And one may even expect that this co-operation will demonstrate some workable scheme for the drafting of standards of quality for many other important heavy chemicals.

Patent Office Records in Danger

FOR many years the government has been grossly careless of its irreplaceable, invaluable records of public business. During the present session of Congress, the House of Representatives decided that an archives building should be constructed and authorized an appropriation for that purpose. But the Senate thought otherwise, and for the present the opportunity has passed for undertaking the plans and construction of such a building.

Among the most serious problems of this sort that demand immediate consideration is the protection of Patent Office records. These original documents are of inestimable value to industry, yet they are stored on rough wooden shelving along the public corridors of the building, forming a fire hazard of almost unparalleled magnitude. In this matter the Department of Interior and the Commissioner of Patents are helpless, for Congress has persistently declined to give adequate storage space or provide any facilities for the care of these documents.

There is now proposed a special Congressional commission of investigation. The problem is so clear that it seems absurd to have such a commission appointed; but it appears to be necessary that the Congressmen see with their own eyes and pass upon the question in their official capacity. Let us hope that this commission will be authorized at once, and that it will be so thoroughly convinced of the need that it will overcome Congressional negligence and provide at an early date adequate housing and filing facilities for these documents. Certainly no one will deny that something must be done to safeguard these records.

Journalism— Technical and Otherwise

WRITING and reading are complementary, both are essential to what is still the most satisfactory method of transferring thought despite modern invention. Skill is acquired by practice, aided by an appreciation of common-sense principles. Facility in reading is governed by the limited service of the human eye, with or without artificial aid to sight, although it is probable that future generations will read more by the ear and less by the eye.

A good writer is recognized by two dominant characteristics: economy in words and an absence of ambiguity in the message. To convey the facts tersely, without the remotest possibility of misinterpretation, without necessitating any mental choice as to meaning on the part of the reader, and without inviting literary criticism this is the essence of good journalism. Effective writing is so unobtrusive that its virtues often pass unobserved. How often need an item or an account in a daily newspaper be read more than once, or any part of it more than once, to appreciate the message? If clarity and brevity be the essence of good journalism, have we not been tardy in paying tribute to the daily press? Is it not somewhat pathetic that a veteran journalist, CHESTER A. LORD, should feel obliged to take up his pen to defend and give credit to newspapers in "The Young Man in Journalism," recently published by the Macmillan Co.? A little retrospection and analysis will show that the bouquet is well deserved.

The main characteristics of contemporary newspaper journalism form an excellent example of the application of common-sense principles, principles that are so logical that they can be commended to the attention of all writers, especially those who contribute to the technical press. The primary essentials are clarity and brevity, in the order named. Ambiguity is not tolerated; there is no justification for excusing it in scientific literature. As to brevity: it may take one man—the author or the editor—a few hours to condense a manuscript 5 per cent, but this may save ten thousand hours of profitless reading by others, besides enhancing the contribution by increasing its clarity. A recognition of these common-sense facts by newspapermen has been responsible for the supremacy of the English-speaking press today. For clarity, there is nothing to surpass the news items in the great dailies; for literary merit, the editorials.

It is well, therefore, that we take the opportunity to pause from our allotted tasks to pay tribute and give credit where both are due. We appreciate the striving for efficiency and accuracy that has marked the journalistic career of men such as Mr. LORD; and we welcome the sane and sensible advice he gives. Although intended primarily for the would-be newspaper journalist, the book we have mentioned should be read by all who put pen to paper. The chapter on composition should be especially valuable to the technical writer. One quotation from an address by LAFCADIO HEARN is worth repeating: "To produce even a single sentence of good literature requires that the text be written at least three times." Repeated revision is essential. It is only by patience that the non-essential can be eliminated, and the simple, direct message framed to take the place of the verbose interpretation of first thought.

The Struggle On the Ruhr

WITH the French grip tightening on the industries of the Ruhr and temporarily strangling the industrial life of that region, and with German resistance intensified to the utmost, the outcome has become largely a question of endurance. It is quite evident, as intimated in our editorial of last week, that the French are in for a long siege that will be terminated only by German capitulation or the introduction of side issues not now in evidence. The important question, then, becomes one of endurance and we may profitably inquire into the respective resources of the contestants.

In Germany fuel and food are the critical factors. Our information is that as far as fuel is concerned, German industry outside the Ruhr can continue to function normally to about the middle of April. After that date the country will be dependent on outside sources for from 50 to 65 per cent of its needs. Food supplies, of course, are growing short; and the situation is strained by reason of the fact that Germany's credit is poor, being limited to the value of her exports. Inasmuch as the latter are decreasing from day to day, it is readily seen that the possibility of providing food from this source is rapidly waning. This means that the government may have to draw on its internal gold reserve, which we are informed amounts to about $175,000,000. Should the situation become desperate enough to warrant expenditure of part of this reserve for food, it is doubtful if even France could or would prevent it.

In France conditions are none too good. Coal is short, credit has been somewhat damaged and commodity prices are rising. Nevertheless from a material point of view the resources of the French are more comprehensive and flexible than those of the Germans and consequently the former probably can last longer in the present struggle. On the other hand, France has to contend with the influence of public opinion on the acts of the government. Whether the French officials entertained any delusions on the immediate outcome of the occupation of the Ruhr, it is certain that the French nation believed that economic relief would be an immediate consequence. What will be the reaction in France when people realize that no great recovery of reparations is to flow from the Ruhr itself and that there is no immediate economic relief in sight? There must be inevitable disappointment; and it is a question how long the government can withstand that reaction. Other questions also may arise to modify the French program, such as outside and independent agitation for the establishment of the Ruhr as a separate state. In addition there are those who believe that the present occupation may extend indefinitely, even to the acquisition of territory. As to this, the French policy is no clearer than when the Ruhr was first occupied.

There has been some talk of intervention by Great Britain or the United States, but it is doubtful if this will come about without invitation. Reliable advices indicate that there is a stronger spirit of unity among the German people than at any time during or since the war. Apparently the French also are at present a unit in support of their government. Under these conditions it must be evident that no successful intervention could be made, as it would not be welcome by either side. Until one or the other or both of the contestants ask for outside aid it is quite likely that no nation will interfere with the present French plans.

Why Should We Be Interested in European Conditions?

BACK in 1920 one of the common plaints of industry was the lack of raw materials. The threat of a world shortage of crude stuffs for our factories was a subject of grave concern. Now, of course, we realize the fallacy of our vision; we were working up the raw materials of the world and when the break came in the world's economic equilibrium we were not long in finding out that industrially we were organized on much too large a scale.

In the process of liquidation that followed it was the producer of raw materials who was the first to be affected. Wherever possible the production of basic materials was curtailed and the industries drew upon existing stocks. The more effectively this process was carried out by the raw material producer, the sooner the consuming industry completed its readjustment. In the case of copper the mines were closed down and it is only with the recent revival in prices that the copper industry has been at all active. Cotton production was curtailed, not voluntarily by the producer, rather through the ravages of the boll weevil. As new rubber plantations came into bearing it became apparent that our supply of this raw material could not be diminished, at least not without the drastic measures which have since been instigated by the British growers. Steel, the most important of all raw materials, was seriously restricted in the latter part of 1919 by the steel strike and later by the walkout in the bituminous coal fields. However, it was the great producer of foodstuffs, the American farmer, that has suffered most acutely. He was not so successful in curtailing his output and the market for his produce had disappeared over night. We awoke to the fact that we had been selling too much on credit to Europe, that our debtors were not working nor was there evidence of their intention to do so. Our loans to European countries, with the exception of England, had been dissipated in military expenditures, in speculation over reparations. Thrift had given way to extravagance.

Dr. B. M. ANDERSON, a noted economist and the chairman of the conference on European rehabilitation which was held by the Institute of Politics at Williamstown last summer, has recently said that there are two ways to straighten out the present situation. In the first place we can sit passively by and watch the process run its course. Gradually the farmers and the industries in this country which are dependent upon a world market for their goods will be forced by foreclosure to contract their operations to the point where production will be balanced by our own consumption. This process will prove long and tedious—10 years is Dr. ANDERSON'S estimate—and it will be consummated only at the expense of sacrificing much of our present industrial system. The other way, and the more fruitful course for us to pursue, is to help get Europe back on her feet. We must assist in restoring the world's economic equilibrium by making a good debtor out of a bad debtor. Drastic reforms are necessary, and they will come only when we can tie together into one settlement the currency, financial and reparation problems of the former belligerents. Additional loans, proposals of debt concellation and intervention in the present political situation will be ineffective unless there is a return to the gold standard, so that national expenditures, in some way or other, can be measured in terms of actual production and enterprise.

Readers' Views and Comments

The Chauffeur Aspires

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your editorial in the issue of Feb. 21 about the Society of Professional Automotive Engineers overlooked the fact that these aspiring chauffeurs were about to jump from the frying pan into the fire. The society aims "to protect its members from increasing laws levied on operation of automobiles," and since its headquarters are in New York, presumably the onerous laws of which it complains are the laws of the State of New York. The laws of New York about automobiles are mild compared to the law which goes into effect after April Fools' Day regulating and defining the practice of professional engineering. This law requires professional engineers to be licensed and sets up certain standards of training and experience requisite to the issuance of a license. This is clearly meddlesome interference with the inalienable rights of those who drive cars of the better sort, and no doubt the society will use the full power of its 4,000 votes to see that its members are not compelled to pay another $25 fee in addition to the heavy burdens they already bear.

On reading Chapter 581, Article IV-A, of the laws of New York, some may have wondered how the Legislature came to couple professional engineering and land surveying in the same breath. As the law is worded, one might think that surveying is the highest form of engineering with which the Legislature was acquainted. The Society of Professional Automotive Engineers might well begin its educational work in Albany before it is too late.

Marketing Ideas

To the Editor of Chemical & Metallurgical Engineering

SIR:—He who can solve the problem of marketing ideas, according to E. H. in your Jan. 3 issue, will bring fame to the successful aspirant, and peace and contentment to many inventors who know the ways of matter but not the ways of men. To this sentiment there should be ready concurrence. If the technician negotiates with a business man, continues our informant, the chances are that the idea he propounds will die. To prove the truth of this one need only record the experiences of thousands; but the remark contains the germ of an idea that, in my opinion, should be fruitful of result or, at least, is worthy of discussion.

The trouble with the majority of inventors is that they have no commercial instinct and cannot bring themselves to acquire it—they can never become business men. One can admit the ability of the ordinary technician to develop an idea through the laboratory stage, but few there are like the chemical engineer of whom E. H. speaks—who can adequately protect an invention from plagiarism or theft. Patenting is a business; it cannot be successful unless ample financial backing is available, unless each and every possibility of business competition is anticipated, unless a suspicious eye is kept on the legal sagacity of competitors.

The marketing of an idea should also be viewed as a business proposition, to be put through by a business man. This is the crux of the matter. Every movie star employs an attorney or a business manager, to arrange, to argue and to bargain—always with an eye to adequate financial return—although his principal usually lacks none of the push required to advance his or her claims to distinction. How much more necessary is it for the scientist or the technician, absorbed in his work and living above the atmosphere of commercial greed, laboring for the love of achievement, as averse to bargaining for remuneration as he is to compromising with facts—how much more necessary is it for him to have a business manager to see that proper protection is secured for ideas evolved, that adequate recompense is arranged for personal services, that fair and equitable agreements only are signed.

I suggest that there is scope for an organization of professional men with commercial training to act as intermediaries between the man of science and the man of business. As the matter stands at present, the inventor-technician has to fight against elements with which he is unfamiliar—against shrewd and highly paid attorneys and patent experts who represent business interests anxious to get ideas for nothing and professional service for next to nothing. The chemical engineer will come into his own when he is protected by the same type of business acumen that has deprived him of his just reward in the past.

Lime Production Statistics for 1922

It has been estimated by the United States Geological Survey that during 1922 there was a material increase in the production of lime. Statistics show that approximately 3,528,000 short tons of lime, valued at $33,057,000, was sold during the past year in the United States, including Hawaii and Porto Rico. These figures represent an encouraging increase of 39 per cent over the previous year, when the production of 34 states decreased and only 8 reported a larger output. Producers of lime on a small scale who supply markets largely dependent upon local demand report a decrease.

Although the scarcity of coal has resulted in the use of wood for fuel by many manufacturers, approximately the same number of plants are reported still in operation. Economic conditions are such that the demand for lime has improved, but prices show a distinct downward trend. Labor has been easily secured, but many transportation difficulties had to be overcome.

Lime for building purposes has reported the largest increase in production, ranging from 3 to 75 per cent among the various manufacturers. Chemical lime has also increased appreciably, reaching a record output of 300,000 short tons, as compared with 107,664 short tons sold in 1921. These figures, however, apply only to refractory lime (dead-burned dolomite) used for patching and lining basic open-hearth furnaces. Agricultural lime, on the other hand, does not report a similar improvement as construction and chemical lime, owing to the farmers' inability to buy the raw material.

The Sterling Chemical Laboratory of Yale University

Description of the Building Erected as a Memorial to John W. Sterling and Which Will Be Dedicated During the Spring Meeting of the American Chemical Society in New Haven—Construction is Planned to Meet Immediate Needs, With Flexibility for Changing Requirements

THERE was John W. Sterling, who went to Yale, took the good old prescribed course, "made Bones," was called Jack by his fellow students, according to the class-book, and was graduated in 1865. He was a quiet man, not addicted to display; he studied law, settled down to practice in New York, did well at solving the problems of corporations and practiced the philosophy of Coué in gaining day by day more and more affluent clients, among whom were finally included the late James J. Hill and Lord Strathcona. He attended strictly to business, did not even take the trouble to marry, lived quietly, and in the course of time went the way of all flesh. When his will was read, after a number of minor provisions, a board of trustees for the residuary estate was named, who should administer it to provide chiefly memorial buildings and professorships for Yale University. And the residuary estate footed up to nearly twenty millions of dollars. It was a cheerful surprise.

The first building to be constructed was the Sterling Chemical Laboratory, which we are about to describe. This is now completed, and will be formally dedicated during the spring meeting of the American Chemical Society, on the one hundred and nineteenth anniversary of the first lecture delivered in Yale by Benjamin Silliman, Sr. Its cost is said to be about two million dollars. The next building will be the Sterling Hall of Medicine and a Museum, both of which are now being erected, and there will follow a new library.

The Sterling laboratory is designed to house all major chemical activities of the university except the department of physiological chemistry, under Professor Mendel and his associates, which remains with the Medical School and will later be provided for in the Hall of Medicine. The work in metallurgy and allied subjects is well cared for by the Hammond Metallurgical Laboratory, a gift to Yale by John Hays Hammond.

At the very outset there was a difficult problem to be met. The site was provided on a hillside, with the front and main entrance at the lower, and the back at the higher, part of the slope. The university corporate authorities and the trustees of the fund desired it to be as a memorial laboratory, monumental in design, and Delano & Aldrich, an eminent firm of architects, distinguished for its good taste in form and line and color, was engaged.

On the other hand, the faculty of chemistry knew very well that the merit of a laboratory consists, aside from needful equipment and the convenience of its arrangements, in good light and a great measure of flexibility. It should be more of a factory than an office. Saw-tooth roofs with overhead northern lighting over a single story appealed to them as the most desirable form of building for this purpose. This is the same conclusion as that reached by Sir James Walker when the new laboratory of the University of Edinburgh was built, to the amazement of the Scotchmen.

Some eminent chemists hold that in building a laboratory one should not aspire to set up more than temporary structures, because much of what is within is bound to suffer corrosion and deterioration, and requirements are sure to change with everchanging and

always new problems to be solved. A perfect layout for one kind of work is wholly inconvenient for that of another type which it may be desirable to take up shortly afterward. So the faculty had the problem to meet to include, in a memorial building, a factory plant which may be changed and shifted about to meet the needs. Now the faculty of chemistry at Yale is a very intelligent body of men, and the same may be said of the corporate authorities of the university and also of the architects. Therefore they did not quarrel over it. They studied the problem, and arrived at a remarkably practical solution.

The front, which extends over the whole width, is a building by itself, divided from that which is back of it by a large hall, of which we show a cut. Here, in the front building, is the vestibule, to the right of which is the office of the chairman of the department, Prof. John Johnston. Coat rooms and class rooms take up the rest of the space on the ground floor. On the floor above are two large auditoriums, one on each side of a great window above the entrance and vestibule, with a preparation room between them, as shown on the main floor plan. The lecture rooms are flanked by two class rooms on either side.

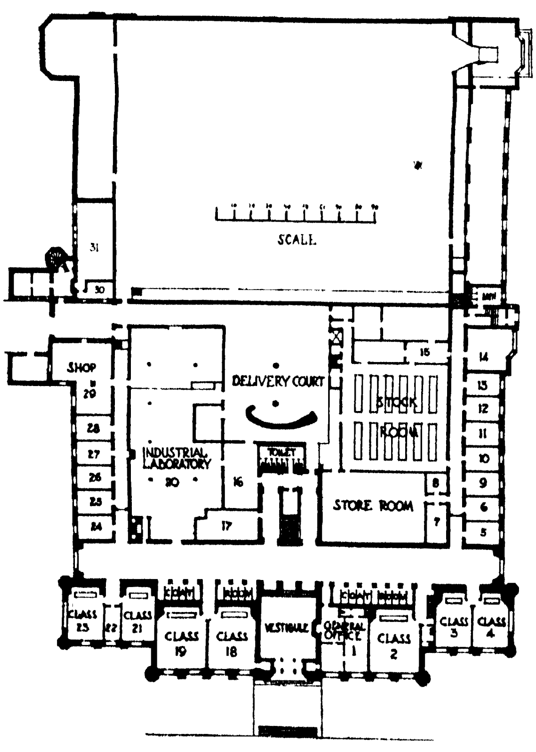
A railway runs through the preparation room and over the platform in each auditorium, so that the set-up for each lecture is made in room 159, and then wheeled either into 160 or 110, as desired. All the platform desks for these two lecture rooms are on wheels. Therefore lectures which involve wholly different apparatus may be given in consecutive hours in the same auditorium, because everything in front of the professor is wheeled away as soon as he is finished, and another train of desks, all prepared and joined together, is wheeled in for the next.

The dividing walls which separate the various rooms in this front building are not structural, so that any change may be made in the size or the arrangement of rooms without affecting the building proper.

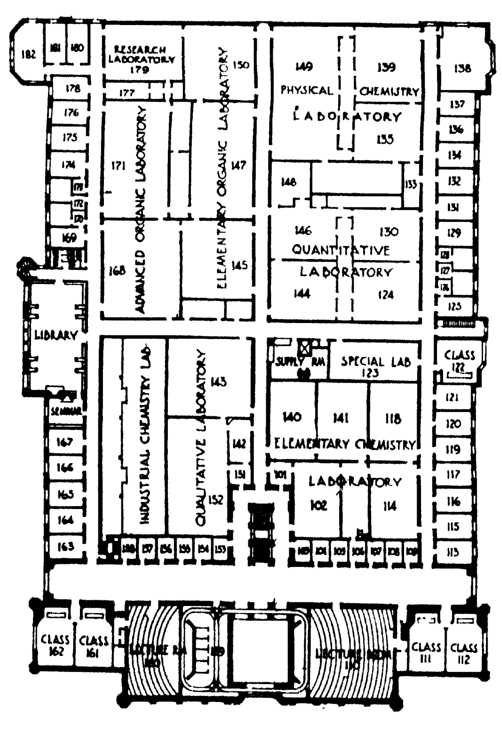
In order to preserve architectural unity and to hide the factory construction within, a narrow structure extends back the full length on each side from the front building. On the lower floor the excavation extends only half way back, owing to the side-hill formation, and in these narrow side buildings are contained offices and research laboratories. Half way back on each external side is a bay, and these include on one side a machine shop, and on the other a larger research laboratory. On the main floor throughout the full length are research laboratories and offices, with the library in the right-hand bay and a class room in that on the left. These two outside buildings constitute a so-called "architectural screen," and extend up one flight above the main floor, providing sleeping apartments for research students on one side, and more research laboratories or additional sleeping quarters on the other.

The above three structurally independent but connected buildings constitute a great U, 328x256 ft. at maximum. Within the U is the undergraduate laboratory proper. The lower floor, which, as we have noted, extends only half way back, contains a delivery court with driveway and store room, stock room and other conveniences, all artifically lighted, and also the laboratory of industrial chemistry. This extends in part through the main floor and is equipped with two galleries and a traveling crane running over the greater part of its length. A connecting room is provided for grinding machinery and furnaces.

The main floor is of two stories in front and one at the back, covered with saw-tooth roof and light from northern exposure. The glazing is heavy wire glass and is double, with air spaces between, thus avoiding



LOWER FLOOR



MAIN FLOOR

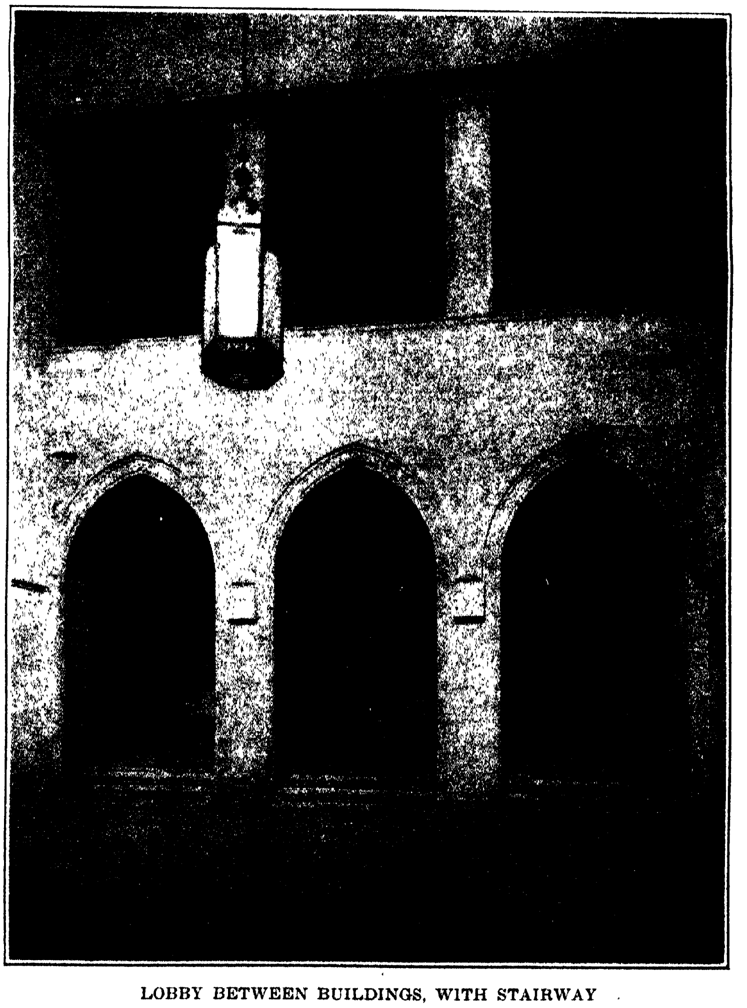
FLOOR PLAN OF THE STERLING CHEMICAL LABORATORY

PRIVATE LABORATORY

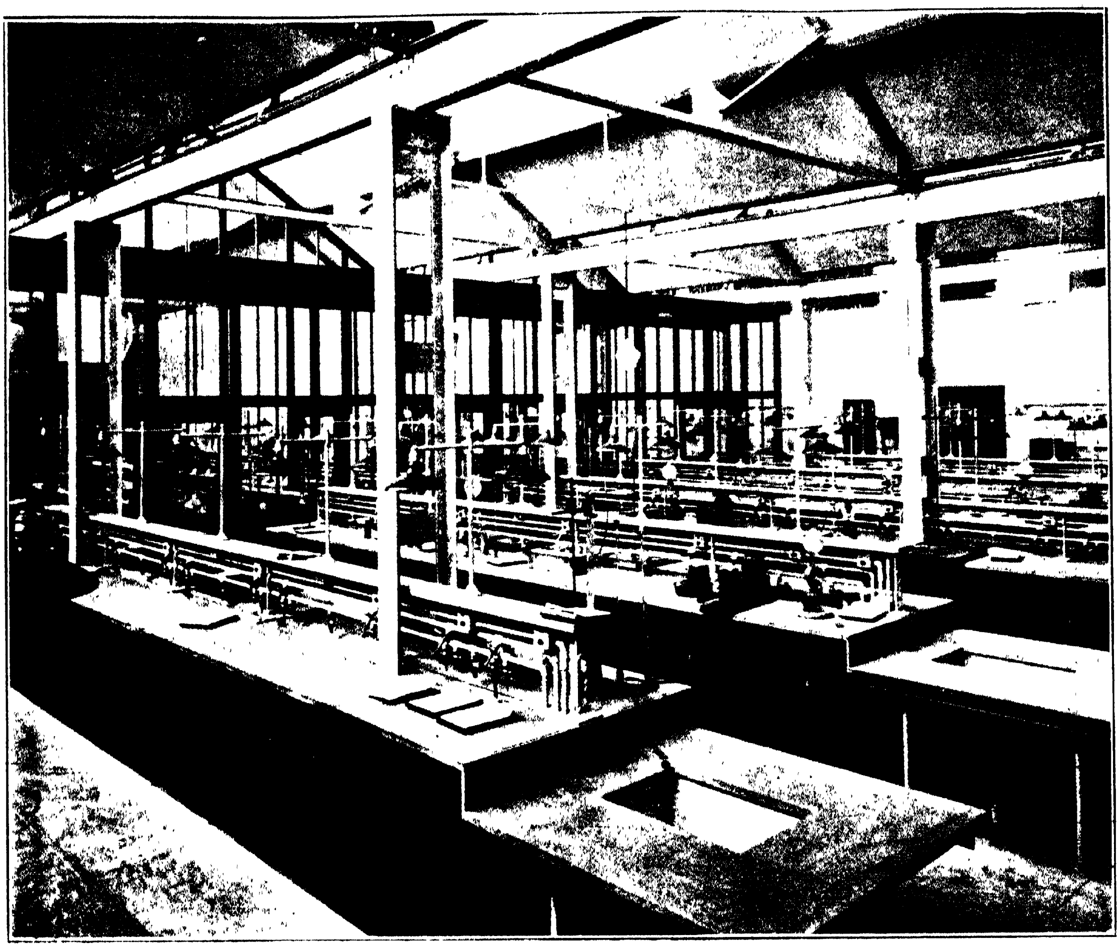
excess heat in summer. It contains the undergraduate teaching laboratories, thus lighted from above, and all partitions may be removed and changed about as needed, without disturbing the building proper. Abundant flexibility is thus assured. Teaching laboratories are restricted to a limited number of students working at one time, thus avoiding the tendency to "study in lockstep," which sometimes occurs if laboratories grow too big. A very clever arrangement in the rooms devoted to quantitative analysis consists in the balance room, which is long and narrow, and extends through the unit as an axis. Swinging doors open into each aisle, which makes the balances readily accessible to the workers. A draft of air blows into this long room and when the doors are opened it blows into the laboratories. This increases the abundant ventilation and avoids a return current with its corrosive effect on the balances. The balance tables cover the entire width of the rooms, which discourages conversation.

The laboratory of elementary chemistry is divided so as to provide places for thirty-two students in each room, and it has a total capacity for eight divisions of students, or 1,280 in all in the suite of five rooms. The qualitative laboratory is in two sections with eighteen and sixty work places respectively. For organic work there are two suites, of which one, of three rooms, is for elementary and the other, of two rooms, for advanced courses. These are also provided with a central balance room and Kjeldahl room. In addition there is a large unit for advanced research in organic chemistry. The physical chemistry department is arranged with balance room similar to that in the quantitative unit, and is provided with thermostat tanks with means for steam and electric heating, cold water circulating coils for cooling, electrical equipment, etc.

In the northeast corner of the plant is a large underground chamber and elsewhere there are special spaces provided for conducting research at constant temperature, at high pressures, for photochemistry, etc. Indeed the scope of major research which may be carried on in this splendid new laboratory is very large and it reflects great credit on the chemical faculty for remarkably shrewd and far-seeing planning by its members. We believe it would be profitable for those chemists who expect to attend the spring meeting at New Haven to bear in mind those lines of research which they would like to pursue, and observe during their visit to the laboratory what provision has been made for meeting such requirements.



LOBBY BETWEEN BUILDINGS, WITH STAIRWAY



PHYSICAL CHEMISTRY LABORATORY, SHOWING BALANCE ROOM BETWEEN SECTIONS

ments. The physical equipment of the laboratory has been selected with great care. In order to eliminate losses from deterioration a drainage system has been installed consisting entirely of chemical earthenware. The lines of this system are straight, without traps or vents. Where the system discharges into the sewer are two large catchbasins. The sinks are also of chemical earthenware, and each is sealed by means of a bell trap which prevents the escape of fumes into the work rooms.

The plumbing fixtures are of brass with dull nickel finish. Standard hose-connection tapers have been used for those which are provided with rubber-tube connections. Hot-water is secured by means of a steam-water mixer, which will provide water at any desired temperature.

Work benches and tables are of Alberene stone, supported by the same cast-iron frames which carry the sinks and plumbing. These frames are attached to the floor by pins which are threaded through washers and permit the benches and tables to be made exactly level. Wooden cabinets are raised from the floor several inches by cement pads.

In constructing the building, red brick and brown sandstone have been used for external walls. Interior walls are of red or buff pressed brick. Floors of the main laboratories in the saw-toothed roof section are concrete. All corridors have tiled floors. The roofs are of glass and "Pyrobar." Care has been taken throughout to protect the structural materials from the action of chemicals.

The general harmony of the planning and of the layout impresses one with the notion that the Yale faculty of chemistry pulls together and is developing an *esprit de corps* which prevents any working at cross-purposes. One gathers the conviction that chemistry is bound to grow at New Haven as one of the great, learned professions, and that this will include industrial research of the highest order.

Impossibility of Accurately Controlling Sulphur Production

Although sulphur deposits have been worked in many parts of the United States, practically the entire output is now obtained from the deep-lying sulphur deposits of Louisiana and Texas. When the wells in this region are once heated, it is not economical to allow them to cool until they have been exhausted. For this reason and because of the desirability of maintaining stocks above ground, more sulphur is often mined during a year than is marketed. A diligent search for new uses for sulphur has ensued and efforts to expand old uses have been made. The further use of sulphur as a fertilizer has received especial attention and most of the agricultural experiment stations are aiding in this research. Experiments in the use of sulphur as a component of acid-proof cement and acid-proof construction material have also yielded promising results. Sulphur is now one of the few commodities of which the price is lower than before the war.

Winter Meeting of the Mining Engineers

Dr. Rosenhain Delivers the Institute of Metals Lecture — Advanced Physical Metallurgy Almost Excludes Consideration of Manufacturing Problems — President Mathewson Pleads for Greater Sociability and Fewer Formal Technical Sessions

FROM the attendance at the various sessions, the interest manifested in the papers, and the discussions which ensued, the Institute of Metals Division appears to be the most active branch of the American Institute of Mining and Metallurgical Engineers. Possibly not so much information on non-ferrous ore dressing and smelting should be expected in a New York meeting, owing to its geographical situation; but this should be no bar to active work among the iron and steel men. Yet the disparity in interest was obvious to many observers.

Institute of Metals Annual Lecture

Perhaps the Institute of Metals profited from a running start. Certainly the technical feature of the first day, if not of the entire meeting, was the annual lecture of the Institute of Metals, given this year by the eminent English metallurgist Dr. Walter Rosenhain. His discussion on "Solid Solutions" was at once erudite, fluent and interesting, and held the close attention not only of the physical metallurgists present but also of many hundreds of listeners who were relative strangers to the subject under study and even of the instruments by which the structure of metals can be studied. Space limitations preclude more than mention of the event at this time—a full digest of the lecture will be presented in these columns next week. At this point, however, it may not be amiss to compliment the Institute of Metals Division, and especially its indefatigable secretary, W. M. Corse, for their enterprise. Announcement that Dr. Zay Jeffries will be the third lecturer insures that the high quality set by Bancroft and Rosenhain will be maintained one year hence.

Social Activities

E. P. Mathewson, the incoming president, stressed the importance of social activities to the success of the Institute in his address at the banquet. His words were homely, but were expressed in a straightforward manner which everyone who knows him would expect. Recalling that the bond of union cementing the A.I.M.E. was of course the technical interests of the members, this will fail if it does not satisfy the social aspirations of the technical men. Dry-as-dust papers must be replaced by those which will elicit animated discussion; these discussions must in some way be carried to the outlying members, either by frequent regional meetings or even by wireless. In other words, the technical interests of the members should be nothing more than an excuse for them to meet, to merge their personalities and become more human.

Award of the James Douglas medal was made to Frederick Laist, manager of the Anaconda Works, for his achievements in the metallurgy of copper and electrolytic zinc. In a brief speech of acceptance he said the achievements, such as they were, were the result of wholehearted co-operation of hundreds of assistants, and he wanted his hearers to know that, and he wanted his assistants to know it, as well.

The usual round of luncheons and theater parties, a dance and a smoker were well attended. On Washington's Birthday a special train took the members to Ansonia, Conn., where they inspected the extensive mills of the American Brass Co. Can it be that this red-letter day ushers in the open door in the brass industry?

Diffusion in Solid Solutions

Dr. Rosenhain, in his lecture, showed how the properties of solid solutions can be explained by considering their atomic arrangement. It was therefore fitting that at a later session Dr. Edgar C. Bain should describe how the X-ray can be used for crystal analysis, and present the information thus found for cored crystals, intermetallic compounds and solid solutions. His two contributions have already been printed in full in *Chem. & Met.* (Jan. 3 and 10, 1923).

In the discussion, Jerome Alexander raised two questions: Whether there was a possibility of a molecular aggregation in solid solutions (such as, for instance, in ice, which is thought to be H_4O_2), and second, whether a spheroidal or colloidal state intervenes between a true solid solution and a two-phase mixture of observable units. Dr. A. St. John reported that he has been able to prepare materials in extremely fine particles. It is well known that a crystal size which may with difficulty be resolved under the microscope produces an X-ray diffraction pattern which contains well-defined narrow bands or lines. As the size of particle decreases, the bands widen, but still have a well-defined maximum. Subdividing the particles still further—to less than colloidal size and approaching particles estimated to contain no more than 125 atoms, the pattern is still observed. Each line has spread out into an extremely broad band—a beam which theoretically should be concentrated at a deflection of 24 deg. occupies the space from 15 to 32 deg., but there is still an observable concentration of intensity at 24 deg. Further subdivision of the particles would mask the true effects still further, but the speaker felt that if he could manufacture a material of cubic crystals containing only 8 atoms it would produce a very cloudy film still having the slightest maximums.

Such markings would be observed superimposed on the pattern of the solid solution if the "stranger" atoms occupied definite positions in the lattice, even though this regularity was interrupted at random every few atoms distance.[1] So far the most minute search had failed to show any such effects in solid solutions; therefore the speaker was forced to the conclusion that the regularity of distribution of stranger atoms in solid solution, though great, was not such that they occupied the northwest corner of alternate cubes, for instance, thus building up an interpenetrating lattice of their own.

In response to the second question—i.e., Does the col-

[1]Dr. Bain has pointed out, however, that if an interpenetrating lattice is displaced regularly, and not at random, a general cancellation of X-rays occurs, and no trace could be found on the film.

loidal state intervene in the decomposition of a solid solution?—Dr. Jeffries expressed the opinion that it necessarily must. Colloidal state is a condition of size; it must intervene between atomic dispersions and microscopic crystals. Annealing of solid solutions at a temperature at which they are stable causes diffusion of stranger atoms. Annealing at unstable temperatures allows precipitation of excess constituent and involves aggregation of stranger atoms; this precipitation starts at random centers, and as the particles grow in size they pass through the colloidal state; but at all times the particle is crystalline, and it grows by adding on one atom at a time. Dr. Rosenhain did not agree entirely with Jeffries' view, even admitting that they were largely speculating about an unknown mechanism. He suggested that when atoms begin to leave solid solution they do not do so easily—conditions must be right. Whether they could aggregate would depend largely upon their own mobility and the expansivity of the lattice in which they were trapped. Consequently precipitation of excess constituent caused a general upset; each tiny crystal of insoluble substance is not well arranged and in turn would be surrounded by masses of mother lattice, badly disturbed or even disintegrated—almost approaching the amorphous condition. If this does not recrystallize quickly, considerable hardening ensues.

Metallography of Aluminum Alloys

E. H. Dix, Jr., of the Army Air Service, presented two papers on the "Preparation of Aluminum Alloys for Metallographic Study" (*Chem. & Met.*, Dec. 20, 1922) and on the "Occurrence of Iron and Silicon in Aluminum." Equilibrium conditions have been worked out in the Eleventh Report of the Alloys Research Committee, but cast alloys or commercial annealings fail to approach this state, and contain some puzzling transition bodies. In very low-silicon ingots (less than 0.10 per cent), iron exists as $FeAl_3$ in very brittle, thin, intersecting plates of blue-gray color (Fig. 1 of the first contribution). With increasing silicon contents—in fact in all commercial ingot—another substance appears, which has been called "X constituent" and is thought to contain iron, silicon and aluminum. It has a habit very similar to $FeAl_3$ and is light gray in color. "X-constituent" and $FeAl_3$ can be differentiated by the fact that the latter retains its color after etching 30 seconds in HNO_3, while the former becomes a watery gray. As silicon goes still higher, all the iron enters the X-constituent, and no $FeAl_3$ is found. "Chinese script" markings shown in Fig. 2 of the first paper etch like this, and are characteristic of aluminum alloys containing equal amounts of iron and silicon. It is often found near the pipe in ingots where needles of $FeAl_3$ verge into it (Fig. 1 herewith) and evidently is the low-melting point constituent in the Al:Fe:Si series. Some unknown constituents occur in cast samples containing more silicon than iron. For instance, Fig. 2 herewith (Al:Fe:Si 97:1:2), contains light gray needles of the X-constituent, rounded purplish particles of silicon, and a rectangular blue-gray constituent whose identity is unknown. Complex needles are often found containing a core of $FeAl_3$, a sheath of X-constituent and an intermediate layer—probably a transition compound which would disappear if properly annealed. These reactions are very slow, however.

Mr. Dix presented some experiments to demonstrate that the X-constituent is certainly not FeSi, but probably contains a relatively small amount of silicon.

"Thermal Properties of Aluminum-Silicon Alloys" were given by Junius D. Edwards.[2] It will be remembered that if an 88.4:11.6 Al:Si alloy be prepared by melting pig metal, it will consist entirely of a eutectic aggregate; but if a trace of alkali metal be added, 15 per cent Si will have to be present before the eutectic is reached. Silicon alloys were shown by Dr. Edwards to have a very low solidification shrinkage, and this accounts for their superior ability to run sound castings, free from pipe. Responding to inquiries about the reason for the bizarre displacement of the equilibrium, Zay Jeffries said that his associates regarded the action of sodium, the modifying agent, as one of obstruction to crystal growth. Sodium is but very slightly soluble in

Fig. 1—Alloy with 0.63 Fe, 0.63 Si; annealed, unetched × 500. Needles of $FeAl_3$ verging into X-constituent with Chinese script habit.

Fig. 2—Alloy with 1.0 Fe, 2.0 Si, annealed, unetched. × 1,000. Needles of X-constituent, rounded particles of silicon, and rectangular mass of unknown intermediate compound

aluminum, even when liquid; therefore the chance of any sodium entering the solid and forming a ternary eutectic was not very great. Probably less than 0.02 per cent sodium remains in the solid alloy. But that small amount which did alloy with the liquid precipitates before the freezing of the aluminum into an infinite number of very fine particles of colloidal size or even less. These really act as an obstruction to the growth of the grains, interfering with the migration of the silicon and aluminum atoms necessary before they can attach themselves to pre-existing nuclei. This sluggish movement of the atoms is also in effect an undercooling of the whole alloy, which in turn is known to promote fine-grained structures, growing from many centers. Other examples of the interference to crystallization offered by foreign particles are well known; notably thoria in tungsten.

[2] *Chem. & Met.*, vol. 28, p. 165 (Jan. 24, 1923); vol. 27, p. 654 (Sept. 27, 1922); vol. 26, p. 750 (April 19, 1922).

SELENIUM AND TELLURIUM

These interesting metals—recovered during the electrolytic refining of copper—were discussed by Victor Lenher, of the University of Wisconsin, after describing their occurrence, chemical relationships, and analytical methods. At the present time about 100,000 lb. of Se is recovered annually—more could be had if it could be sold. It costs about $2 per lb., and is largely used in the manufacture of ruby glass and as a decolorizer of white glass. A small amount of crystalline modification is used in the selenium cell, which has the remarkable property of responding to light waves. Selenium oxychloride is a solvent for a wide range of organic substances.

Tellurium resembles antimony in appearance. But few uses have been found, and its production is nominal, although 150,000 lb. of the element could be recovered annually. Some of the best ceramics are colored by tellurium.

BRITTLE MALLEABLE IRON

It has long been known that perfectly normal malleable iron, having a ductile black fracture, will be converted by hot-dip galvanizing into a brittle material, having a white coarse crystalline fracture and low resistance to shock. Preliminary work by the Eastern Malleable Iron Co. determined that this phenomenon is not due to occlusion of hydrogen during the pickling process. To locate the trouble, a careful research was directed by W. R. Bean, and it was found that high phosphorus and silicon induces these brittle intergranular fractures in malleable iron quenched from 850 to 900 deg. F. Safe analyses are below 0.06 P with 1.50 per cent Si, and 0.22 P with 0.50 per cent Si. In the experiments, a nest of test bars was cast from a crucible furnace; one of these was tested as annealed, and others after galvanizing and after various heat-treatments. Chemical analysis of these melts was systematically varied, and when the results of Humphrey or Alsen notched bar tests were plotted against phosphorus content, it was quickly found that no deterioration occurred in low-phosphorus bars. Galvanizing followed by very slow cooling or quenching in oil at 600 deg. F. caused little deterioration in high P and Si bars; but if these same bars were quenched from the zinc tank in cold water they showed unmistakable damage, almost exactly matched by other bars heated in a muffle and quenched from that temperature. Quenching is therefore the culprit. Control of phosphorus is, however, the easiest way out of the difficulty.

Slow bending (the Humphrey test[*]) is an excellent test for brittleness. Single glow impact (Olsen or Izod test) is supersensitive, while ordinary tension tests are not suitable.

THERMAL CONDUCTIVITY OF ALLOYS

A research into alloys used for gas-engine pistons and bearings was reported by Messrs. Williams and Bihlman, of the General Motors Research Corporation. They describe an apparatus whereby the thermal conductivity of commercial alloys for such purposes may be measured by heating one end of the bar and measuring the calories conducted to a flow colorimeter at the other end. A complete determination requires about 6 hours. The conductivity of No. 12 aluminum alloy (92:8 Al:Cu) is not affected by the method of casting or the amount of return scrap used. Bearing metals are in general good insulators. Copper is quite sensitive to purity and heat-treatment. Results follow (*K* is the calories transmitted per second through a cube, 1 cm. on a side, when opposite faces differ by 1 deg. C.):

Alloy	Temperature, Degrees C.	*K*
Silver	100	0.99[illegible]
No. 1 aluminum, hard drawn (99.5 pure)	79 to 193	0.47
No. 12 alloy (92.8, Al Cu)	85 to 250	0.34
S.A.E. Bearing Alloys		
No 10 (92.5:3 6.0.2:3.7, Sn:Cu Pb Sb)	50 to 100	0.092
No. 11 (86 9 5.2·0.1:7.9, Sn·Cu Pb Sb)	50 to 100	0.062

Electrolytic copper wire	90 to 210	0 89
Cast electrolytic or lake copper	90 to 225	0.76
Arsenical copper	100 to 230	0.51

BRIGHT ANNEALING COPPER WIRE

In order to bring fine copper wire into proper condition it has been the practice at the Westinghouse Co. to anneal it on spools in an atmosphere of natural gas at 350 deg. C. However, the outer layers were ruined by a thin layer of oxide, formed from small quantities of oxygen in the gas. P. E. Demmler found that the trouble can easily be corrected by previously passing the gas over copper at 600 deg. C., which acts as a catalytic agent in forcing combination of oxygen and hydrocarbons below the ignition temperature. The action consists essentially of oxidation of the copper, followed closely by its reduction by methane, the end products being CO_2 and H_2O.

Other papers on non-ferrous alloys have been printed in *Chem. & Met.*, as follows: "Study of Bearing Metals," by C. H. Bierbaum; "Tests on High-Tin Bearing Metals," by P. W. Priestley; "Determination of Gases in Metals," by H. L. Simons.

Mines Bureau Tests Detonators

A series of tests has been started at the explosives laboratory of the Bureau of Mines at Pittsburgh, Pa., to determine the comparative efficiency of cyanuric triazide as a detonating agent by comparing its minimum detonating charge with pure fulminate on TNT, tetryl, TNA and ammonium picrate. The physiological properties of cyanuric triazide are also being studied. These tests include application to the skin to study irritating properties and tests on animals when taken in food and breathed as vapor.

These tests are part of a general series of tests being conducted at Pittsburgh to fix standards for detonators. Included in the materials tested will be the usual mixtures of mercury fulminate and potassium chlorate, trinitro-resorcin, TNT, tetryl and other compounds used in detonators. An attempt will also be made to determine the relative value of these different substances as material for detonators.

Bureau of Mines Works on Explosives

During the past year methods have been devised at the explosives laboratory of the Bureau of Mines, Pittsburgh, Pa., for determining by tests the relative sensitiveness of explosives to detonation and also their fire-resisting qualities. Further work will be done to develop these tests. When standard tests have been established, a number of different classes and grades of explosives will be tested by these methods. An investigation has also been made of the water-resisting properties of a variety of explosives.

Silver Jubilee Meeting, American Ceramic Society

Gathered at the Birthplace of the Society to Celebrate Its First Quarter Century of Constructive Service and to Honor the Founders and Charter Members, Over Five Hundred Ceramic Technologists Divide Their Time Among Technical Discussions, Social Diversions and Plant Visits

EDITORIAL STAFF REPORT

BEFORE the twelfth annual convention of the National Brick Manufacturers' Association, held in Pittsburgh Feb. 16 to 18, 1898, Elmer E. Gorton presented an excellent technical paper on the subject of terra cotta glazes. This constituted a decided innovation in the programs of this association, and while the novel method of presentation aroused temporary interest, it was evident that only a very few of those present could understand or even appreciate technical discussions. Realization of this fact led to a consideration of the possibility of forming a small society of ceramic technologists which should form a section of the N.B.M.A. or be independent, as deemed best. Action was taken on Feb. 18, 1898, in the parlors of the Monongahela House during a meeting attended by Elmer E. Gorton, Samuel Geijsbeck, Edward Orton, Jr., A. V. Bleininger, W. D. Richardson, Ellis Lovejoy, William D. Gates, Carl Giessen and Gustav J. Holl. Mr. Orton was asked to act as provisional secretary and a list of persons who should be invited to join in the formation of the proposed society was agreed upon. As a result, twenty signified their willingness to attend the first meeting, Feb. 6, 1899, and thus became charter members. With the exception of Mr. Holl, those mentioned above were included and in addition the following: Charles F. Binns, Stanley G. Burt, J. Parker B. Fiske, Karl Langenbeck, Ernest Mayer (now deceased), Herman C. Mueller, James Pass (now deceased), H. Ries, Edward C. Stover, Francis W. Walker, Herbert A. Wheeler, W. H. Zimmer.

For the dual purpose of observing the twenty-fifth anniversary of the American Ceramic Society and of honoring these charter members, over five hundred of the present membership of nearly nineteen hundred gathered at the William Penn and Fort Pitt Hotels, Pittsburgh, during the week of Feb. 12. In order to relieve the technical programs of reviews covering the twenty-five years, these were made the theme of the January *Journal of the American Ceramic Society*—a volume of 350 pages to which the reader is referred for progress reports on all phases of ceramic technology, education and research during the past 25 years. During the general session and the social functions, however, opportunity was afforded to make the newer members acquainted with those who conceived and organized the society.

INDUSTRY VIEWED FROM MANY ANGLES AT GENERAL SESSION

Opening the general sessions Monday, Feb. 12, President Frank H. Riddle touched upon many phases of the developments during the past year which indicate that the society is progressing most satisfactorily along the lines of increased service. The year 1922 was in many ways experimental, all activities with the exception of advertising were centralized in Columbus with a full-time general secretary who also served as editor, the journal was enlarged and in addition a bulletin containing items of wide interest but of less permanent value than the technical papers was started, at first separate but later a section of the journal. Although the expense of these extensive improvements was not fully covered by the income, it was felt that conditions were highly satisfactory, for there was a substantial increase in membership and in advertising revenue, the latter in spite of the fact that some of the trade papers in the field showed a decline for the year.

Turning to the future, President Riddle called attention to the possibility of bringing the mechanical equipment more in line with the developments in other industries. The publication of a ceramic handbook was urged both as a tool for workers in the industry and as a means of bringing ceramic engineering more fully to the attention of the technical world. Along educational lines, emphasis was placed on two classes of men needed by the industry: young men receiving instruction in trade schools while serving their apprenticeships, high-grade men for research or eventual plant executives. As long as plant foremen and executives are not interested in ceramic engineering, true progress will be impeded.

Several special reports were adopted in addition to the customary ones which were preprinted and passed without reading. Among the former were: approval of the National Research Council's plan to raise $200,000 over a period of 3 years for the compilation of data on numerical constants; student membership rate of $4.80; granting of charter to Rutgers College Ceramic Club and Student Chapter; budget of $40,000 for 1923, which will require 400 new personal members, 100 corporations and 11 additional pages of advertising.

TALKS BY PROMINENT MEN

Among the prominent speakers at the opening session was W. L. Clause, chairman of the board, Pittsburgh Plate Glass Co., who outlined in a comprehensive way the probable effect upon American industry of certain European and domestic economic problems, such as the inflation of the mark, reparation, the allied debts, the inadequacy of our transportation system and the labor situation. His general conclusion was that it is possible for this country to enjoy a large measure of prosperity regardless of European developments and that the domestic problems are far more important.

B. E. Salisbury, president, Onondaga Pottery Co., emphasized a number of important points in considering research from the point of view of the manufacturing executive. In his estimation a research worker should be a real man first and a scientist second, for without the ability to get along with and really co-operate with plant men, he can never rise above routine.

An earnest appeal for the development of the American decorated chinaware industry along more artistic lines was made by Prof. Charles F. Binns. Mass production of open stock patterns is convenient for manufacturer and consumer, but tends to stereotype methods by stressing quantity rather than quality. At least the decorating department should be supervised by a trained designer. It might also be possible to start a small department for fine ware which would probably not be profitable at first, but which would go far toward the establishment of a reputation similar to that enjoyed by foreign manufacturers.

Speaking from the full experience of a life of service, Edward Orton, Jr., laid down some fundamental characteristics of engineering education. Briefly, he holds that character development should be the aim of education and that engineering training, being founded on scientific truths and quantitative thinking, fits a man not only for his profession but for general service to the community as well. He urged every young engineer to interest himself in some phase of public activity.

Brief talks by Dean M. E. Cooley, University of Michigan, on the work of the Federated American Engineering Societies, by Dr. H. Foster Bain on the ceramic investigations of the Bureau of Mines, by Dr. E. W. Washburn on plans for obtaining ceramic data for the International Critical Tables and by A. L. Scott on the research work of the American Hotels Association completed the regular program.

A. F. GREAVES-WALKER
President American Ceramic Society

An unexpected feature was a talk by Dr. Walter Rosenhain, superintendent, metallurgical department, National Physical Laboratory, Teddington, England, who was in Pittsburgh to deliver a series of lectures at Carnegie Institute of Technology and kindly consented to outline some of the work conducted during and since the war along ceramic lines. A number of interesting developments were brought out such as the preparation of a gastight muffle for use in melting carbon-free ferrous alloys by having a body which would just sinter at the temperature required. A thermocouple protection tube having a high-alumina body has been developed which can be welded in an oxy-acetylene flame when cracks arise. An unusual phenomenon is that this body will crack if heated slowly, but may be plunged quickly into the oxy-acetylene flame without damage.

Charter Members Honored at Social Functions

At the banquet Monday evening following a program which included an address of welcome by Prof. Alexander Silverman, chairman, Pittsburgh District Section, response by President Riddle and brief talks by Dr. Rosenhain, Dean Reavis of the University of Pittsburgh and Karl Langenbeck, the charter members present were formally introduced and in their presence Colonel Orton administered the oath of office to those elected for the year 1923-1924: A. F. Greaves-Walker, president; R. D. Landrum, vice-president; Ross C. Purdy, secretary; Ralph K. Hursh, treasurer; R. R. Danielson, trustee. In concluding the ceremonies, Toastmaster L. E. Barringer presented Colonel Orton with a handsomely bound book containing letters from about fifty former pupils expressing appreciation of what his inspiration and guidance had meant to them.

Tuesday evening a smokerette was held in the ballroom of the William Penn. Dancing followed entertainment, which varied from "community" singing to the reading of a very serious paper on the "Plasticity of Clay" by Dr. B. Rouhland, a German scientist scheduled to appear before the Terra Cotta Division on Wednesday, but granted permission by Dr. Tillotson to speak on this occasion. Serious and forcible objection to some of the professor's statements soon developed and a lively scrap seemed imminent until it was explained that the "professor" was only one of the entertainers.

Throughout the week the products of nearly fifty organizations representing each industrial division were on exhibition at the Fort Pitt Hotel.

Mention should here be made of the several local committees without whose efforts this meeting would not have been possible. These, with their respective chairmen, are as follows: Executive, A. F. Greaves-Walker; transportation, C. C. Phillips; hotels, A. H. Chandler; publicity, A. W. Kimes; service, H. G. Schurecht; smokerette, R. M. Howe; banquet, Alexander Silverman; reception and trips, J. Spotts McDowell; finance, H. L. Dixon; entertainment of ladies, Mrs. A. F. Greaves-Walker.

It has been decided to hold the 1923 summer meeting in connection with a boat trip between Chicago and Detroit. Atlantic City was chosen for the next winter meeting, while a trip to the Pacific coast is contemplated for the summer of 1924.

Plant Visits

Probably no convention held in Pittsburgh has had the opportunity of inspecting more manufacturing establishments. A choice was offered of four trips on Thursday and three on Friday covering a total of twenty-four industrial plants ranging from chinaware, through glass, refractories, insulators and enameled ware, to byproduct coke ovens, zinc works and the largest tube mill in the world. All the trips were well

attended. For the courtesies extended the members express their hearty appreciation to the management of the several plants and to those who looked after the arrangements.

Divisional Meetings

Because of inherent diversities of interest, the society is grouped into industrial divisions. At present there are seven, as follows, the numbers given being the members who registered in the respective divisions for this meeting: Art, 23; Enamel, 65; Glass, 49; Heavy Clay Products, 65; Refractories, 73; Terra Cotta, 26; White Wares, 81. Although each division presented an important technical program on Tuesday and Wednesday at the Fort Pitt Hotel, space limitations preclude a full report of all and emphasis will be placed on refractories, glass and enamel.

Refractories Division

Refractory Raw Materials

In the absence of G. H. Ashley, State Geologist, the flint clay situation in Pennsylvania was discussed by his assistant, Mr. Stone. From all indications there are sufficient quantities of soft clay, flint clay and ganister available to supply the requirements of the refractory manufacturers for many years to come.

R. T. Stull was inclined to disagree with the previous speaker regarding the adequacy of supply of high-grade fireclays. He presented the results of experiments in the preparation of refractories from some of the kaolins and bauxitic clays found along the coastal plains of Georgia. Test lots of these brick have been installed in various types of furnaces and have given uniformly successful service, excelling fireclay and even silica in certain cases.

Properties of Refractories Considered From Many Angles

Progress in the difficult problem of establishing specifications for refractories for coal-fired boiler use was reported by R. F. Geller. Through the co-operation of Stone & Webster, specimens of forty-two different firebrick were obtained from power plants located in various parts of the country. These were subjected to a large number of tests and the results plotted in order to determine those properties which it would seem desirable to specify.

In studying the action of slags upon diaspore, fireclay, silica, magnesite and chrome brick, R. M. Howe, S. M. Phelps and R. F. Ferguson ground the refractories through 80 mesh, added varying amounts of five typical slags (such as blast-furnace, acid open-hearth, basic open-hearth, etc.) and determined the fusion point of the mixtures. When plotted, the results give a comprehensive idea of slag action which agrees with practical observations.

A somewhat similar study involving the effect of alkalis and alkaline earths upon the fusion points of refractory bodies varying in both directions from kaolinite, $Al_2O_3.2SiO_2$, was made by Prof. A. S. Watts. In high-alumina bodies such as $Al_2O_3.1\frac{1}{2}SiO_2$, the alkalis were found to be more active fluxes than the alkaline earths, while with bodies containing more silica than kaolinite the reverse was true.

Professor Watts and R. M. King also reported their work toward the development of a laboratory apparatus for the determination of heat transfer valves which will combine commercial accuracy with ease of manipulation.

Silica Cement

Valuable data on silica cement were given by E. N. McGee. This cement is made by grinding silica bats and adding just enough plastic clay to give workability. In some cases ganister is substituted in part for the bats so that the percentage composition might be: Bats, 50; ganister, 25; plastic clay, 25. The bonding properties are slight even when hot, although a fairly good bond may be obtained by heating and cooling under pressure. Recently it has been found that the addition of molasses to the water will result in a much stronger bond without detriment to the refractoriness. Indeed, a mixture of ground silica or bats and molasses will adhere so firmly to brick that it may be used for patching.

Consumers' Problems

Requirements which would have to be met by the ideal refractory for stokers were treated in some detail by G. I. Bouton. Present operation at 3,000 deg. F. imposes severe temperature conditions in addition to the slagging troubles encountered with many types of coal. The question of refractory requirements for suspended boiler arches was briefly outlined by J. E. Harlow.

Speaking on refractory problems in the oil-refining industry, Alan G. Wikoff stated that the shell type stills used so extensively for handling crude, coking and cracking do not impose very severe conditions on the refractory linings of the settings. With stills of the tube type such as one used for topping and in some cracking processes, requirements become more severe, particularly in the latter case, where firebox temperatures in the neighborhood of 2,600 to 2,800 deg. F. are encountered.

Burning of Refractories

Some of the factors which have apparently operated to prevent the successful application of producer gas in firing clay wares such as refractories which require high temperatures were outlined by W. D. Richardson. In his opinion the continuous regenerative compartment kiln offers great possibilities along this line.

It is not always possible to scrap less efficient kilns in favor of more efficient ones on account of the expense involved. In such cases, however, it is possible to increase the efficiency of the old installation by observing certain precautions and also by exerting a more careful control over labor costs. The effects of putting kiln firemen on a bonus system were set forth by L. C. Hewitt. Standard rates were developed from time studies and the average efficiency (allowing 50 per cent for fatigue) was found to be 67.5 per cent. This was made the base and a bonus was paid above this, 15 per cent for 100 per cent efficiency, 30 per cent for 120 per cent efficiency, etc.

J. H. Krusen's paper on the insulation of periodic kilns was read by E. E. Ayars. An average fuel saving of about 15 per cent is indicated when kilns are insulated with a material such as Sil-O-Cel.

Problems in burning silica brick were considered by Dr. F. A. Harvey, with particular reference to attempts to determine the most efficient heating and cooling schedules for round down-draft periodic kilns. Base

metal couples were used up to 1,800 deg. F., when these were removed and further observations made by an optical pyrometer sighted on a brick set in the center of the kiln. Defining a properly burned silica brick as one having a residual expansion of from 0.4 to 1.4 per cent, many interesting observations were noted. For one thing, the quality of the coal was found to be most important. With 13,500 B.t.u. coal it was found impossible to burn the brick properly, 14,000 B.t.u. coal required 11 days' burn, while 14,500 B.t.u. coal cut the time to 8 or 8½ days. The average time is 10 days to burn, 7 days to cool, but the harder the burn the more careful must be the cooling. Although the maximum rate of heating and cooling has not been determined, the time of soaking or holding at maximum temperature has been pretty well determined. If the maximum temperature is 2,400 deg. F., 72 hours is required, while if 2,600 can be obtained, 24 hours will give a coke-oven burn—that is, 0.4 per cent residual expansion.

Colloquium on Metallurgical Requirements

Wednesday afternoon was devoted to an important colloquium on metallurgical requirements of refractories, led by Dr. D. A. Lyon, Bureau of Mines. Abstracts of the papers presented will be published in a subsequent issue.

Division Officers

For the coming year, the officers of the Refractories Division will be: E. E. Ayars, American Refractories Co., Joliet, Ill., chairman; Dr. F. A. Harvey, United States Refractories Corp., Mount Union, Pa., vice-chairman; R. F. Ferguson, Mellon Institute, secretary.

Vice-President American Ceramic Society

Glass Division

Aside from the technical papers, some of which are abstracted below, the Glass Division entered into several instructive discussions on such practical subjects as the question of glass tank water coolers and the sulphuring of glasses.

New Data on Physical and Chemical Properties

Resistance of soda-lime glass to water was determined by L. A. Palmer, of the Glass Container Association, by filling bottles with water and immersing them for 6 hours in a solution maintained above the normal boiling point of water. The water inside the bottles was then titrated for alkali as a measure of the action of water upon the glass. It was found that the results fell into three groups, one of which was quite evidently unsuitable for container use.

Under the title "Skiagraphic Study of Fabricated Glass Articles," C. D. Spencer and A. E. Badger reported the results of an investigation in which it was shown that by proper control of the physical structure of the glass at the line of contact it is possible to join successfully g.asses of varying coefficients of expansion. A great deal of the breakage occurring in fabricated articles is due to improper physical structure at the joint.

Petrographic studies of the different forms of silica and of corundum crystals were shown by Herbert E. Insley to be of importance in determining the origin and cause of stones in glass.

Mechanical tests on window and rolled sheet glass by Arthur E. Williams brought out some instructive data on the tensile strength. The product of different factories was found to vary widely, even as high as 50 per cent. Tensile strength of window glass was found to range from 10,000 down to 6,000 lb. per sq.in., thinner pieces testing stronger than thicker ones. Under these tests, non-shatterable glass and wire glass were not found to be any stronger than ordinary glass, while polished plate tested weaker than the drawn.

Further work on tensile strength was reported by Dr. J. T. Littleton, who endeavored to eliminate the surface effects which have influenced previous determinations and found that the strength thus obtained is considerably higher than hitherto recognized.

Rapid routine determinations of refractive index are made possible by a method devised by H. P. Gage and Dr. J. C. Hostetter. Glass in the form of a rod is immersed successively in a series of liquids of known index of refraction until the deflection of an external straight object observed through the rod shifts from left to right or *vice versa.* The true index of the glass then lies between these two values and by adjusting the temperature of the liquid until there is no deflection it is possible to calculate the refractive index quite accurately, provided, of course, that the temperature coefficient for the liquid is known.

Viscosities of soda-lime-silica glasses between 800 and 1,500 deg. C. were determined by Dr. E. W. Washburn and G. R. Shelton in a specially designed torsion type machine calibrated by means of glucose-dextrose mixtures rather than the customary castor oil, because the former are sticky and thus behave more like glass than the latter, which is oily. Calibration curves were found to be not the same for all the different viscosities and it was necessary to correct for this.

Surface tension measurements on these glasses were made by the same authors, using a platinum cylinder attached to a Joly balance, figures in the neighborhood of 200 dyne-cm. being obtained. The surface tension was found to increase with decreasing temperature, but the temperature coefficient is very small.

Gas producers, application of producer gas and the use of recuperators in connection with closed pot furnaces were considered by W. B. Chapman, while A. E. Blake presented additional material on producer gas and gaseous fuels which will form a chapter in Professor Silverman's forthcoming book on the American glass industry.

Two types of furnace for melting glass in the laboratory were discussed by A. E. Badger and S. C. Spencer. One utilized a stranded tungsten wire wound on an alundum core and operated in an atmosphere of purified nitrogen, while the other was of the spiral carbon resistor type.

That it is possible to substitute oil for producer gas in a tank furnace operating in New England was demonstrated by F. S. Thompson. It was found that the tank temperature could be maintained within narrow limits and that the control necessary on a Westlake machine could easily be obtained. In this instance fuel oil at 4½c. per gal. was substituted for coal at $4.50 per ton.

Glass Wool Used for Heat Insulation in Europe

Of the many substitutes developed in the Central Empires under the stress of war-time necessity, one of the few which has survived is glass wool for heat insulation. Arthur D. Saborsky outlined the method of preparation, which consists in winding a number of parallel threads continuously on a revolving drum, and gave some heat transfer values which indicate that the material is more efficient than mineral wool or 85 per cent magnesia. On account of its fibrous nature it can be formed into pads which permit convenient application. It will also stand higher temperatures than some of the other materials.

Recent observations of the European glass industry lead H. W. Hess to the conclusion that there will eventually be little difference between European and American conditions, because of the increasing use of American machinery abroad.

Glass Division officers for the ensuing year were elected as follows: A. R. Payne, chairman; J. H. Forsyth, vice-chairman; A. E. Williams, secretary.

Enamel Division

Preliminary report on warpage of sheet iron and steel in the enameling process was made by R. R. Danielson, who presented his results according to a system which gives a quantitative measure of the warpage, thus doing away with such general descriptive phrases as "slightly warped," "badly warped," etc. Mr. Danielson also reported that the work on cast iron was still in progress, but that it was hoped to complete this during the coming year.

A committee was appointed to survey by questionnaire all types of enamel furnaces. It is expected that this survey will bring together data which will prove valuable and helpful to the entire industry.

With the exception of resistance to acids, very little has been reported on the relation between enamel composition and properties. R. R. Danielson and B. T. Sweely undertook a study of the relation between such properties as expansivity, strength and acid resistance as well as the effect of relative fit of ground and cover coats on resistance to impact and thermal shock. Fourteen ground coats and white cover enamels were applied to about 600 8-in. dinner plates. The enameled ware was tested for resistance to impact, thermal shock and acetic acid. Expansivity and compressive strengths of the enamels were determined before applying to the steel. The conclusions were as follows:

Replacement of B_2O_3 by Na_2O in enamel increases the coefficient of expansion and fishscaling diminishes at the same time.

Compressive strength of ground coats is decreased by replacing B_2O_3 with Na_2O, although the reverse is true in the case of cover enamels.

Impact on parts of ware not free to deflect, such as curved corners at bottom, gives a measure of the strength or toughness of the enamel as applied on the steel. Resistance of enamel on corners to impact is apparently a function of the inherent strength of the enamel rather than of its fit on the ware.

For greatest resistance to thermal shock, ware should be coated with a ground coat having a coefficient of expansion equal to or preferably greater than that of the cover enamel.

Acid resistance, while dependent upon composition, is not affected in the same way for all enamels. For the cover enamels studied, resistance to acids was found to decrease as B_2O_3 was replaced by Na_2O.

Further information on acid resistance was given by E. P. Poste in the fifth part of an extended series of studies on the relative action of acids on enamels.

Tin Oxide Substitutes

Zirconium oxide and sodium antimonate were found by R. R. Danielson and M. K. Frehafer to be apparently the best substitutes for tin oxide, ranking very close to it. Zirconium silicate came next, although here the purity is a very important factor. Opacity does not always increase with an increase in the amount of opacifier used and the proper calcination of the opacifiers is of importance.

Visual estimation is not an accurate method for determining the opacity of enamels, although it may be suitable for classifying enamels for stove work and table tops. For accurate determination of reflecting value, the method of the Colorimetry Section, Bureau of Standards, should be used.

W. F. Wenning also presented some interesting data on the use of zirconia in enamels.

Bentonite, a highly colloidal clay, has a much greater suspending power than ordinary enamel clays, the ratio being about 5 to 1 in favor of bentonite. Its use, as pointed out by M. E. Manson, makes possible a decided reduction in the amount of raw material to be added to the frit. Some possible disadvantages were also considered.

Problems in the design and operation of a sandblasting room were discussed by F. G. Jaeger. Downward draft of 6,000 cu.ft. per minute was found effective in keeping the dust from rising more than 2 ft. above the floor, resulting in improved working conditions. Two men work together, one loading castings on a truck outside the chamber while the other works inside, alternating positions as the ware is changed. They wear heavy rubber gloves and canvas helmets with the seams protected with rubber sheeting. The abrasive—very hard silica sand—is applied by compressed air at 80 lb. gage through best quality rubber-lined hose terminating in chilled cast-iron nozzles with ⅜-in. opening. These nozzles last only about an hour under continuous use. Defective ware may be freed from enamel very economically by placing it behind the new work.

Further operating results on an intermittent gas-

fired enameling furnace previously described were given by H. H. Clark. Previous requirement of 1,800 cu.ft. of 500 B.t.u. gas per hour firing 600 sq.ft. flat ware (690 lb., representing 240 pieces) to a maturing temperature of 1,700 deg. F. has now been reduced to 1,260 cu.ft. With gas at 50c. this means a fuel cost of 63c. per hour, 10c. per 100 sq.ft., or 9c. per 100 lb. After 3 years' operation no repairs have been found necessary.

Several installations of electric enameling furnaces were described and illustrated by E. F. Collins. H. E. Davis presented data on an enamel smelter design which has already been noted in *Chem. & Met.*, Feb. 21, 1923, page 364.

New officers of the Enamel Division are: H. F. Staley, chairman; R. R. Danielson, secretary.

Synthetic Vanillin Manufacture

Interesting Information on Properties and Processes for Preparing This Important Synthetic Organic Chemical

By Burton G. Wood
Consulting Chemist, Pittston, Pa

VANILLIN is one of the most important perfume materials. Chemically it is methoxyprotocatechuic aldehyde, a substance occurring in the form of white needle crystals or plates. The melting point of pure vanillin is 82.5 deg. C. and boiling point is 285 deg. C. It decomposes when boiled at atmospheric pressure, but may be distilled under a vacuum of 0.1 in. Even at this low vacuum, however, there is considerable resin formed, which increases rapidly as the vacuum is lowered.

The crystalline structure of vanillin depends entirely on how the hot aqueous solution is cooled. If the solution is stirred while cooling or while the first crystals are forming, the entire lot can be obtained as plates. If the solution is allowed to stand until the first crystals have formed and then is stirred slowly, the crystals will be mostly needle shaped. At times long fibrous crystals, generally termed "cotton," are formed. This formation is due to concentration and method of cooling and not to the presence of silicates in the water, as has been reported. Needless to say, the crystalline structure has nothing to do with the aromatic properties of vanillin.

From Natural Sources

It has been contended by some, and with just cause, that the aromatic properties of vanillin have been greatly overrated. At a recent meeting of the Flavoring Extract Manufacturers Association several samples of vanilla extract were displayed which contained no vanillin but simply the resins from the vanilla bean. These samples, it was declared, had even a better odor than that of a vanillin solution with which they were compared.

The natural source of vanillin is the vanilla bean, from which it is extracted and sold as vanilla extract. The growing of vanilla beans is a commercial enterprise in some countries, especially in Mexico, in Java, in Madagascar and various other semi-tropical colonies of France and Great Britain and in Brazil. The bean, which is 6 to 8 in. long and 2 to 4 in. thick, is collected in the fall, just before it ripens. The final process consists of sun drying and finally artificially drying the bean until it assumes a dark brown or almost black color. Even the vanilla bean which we associate with pleasantness through its odor induces a skin disease by an oily discharge while curing. Vanilla beans contain from 1.75 to 2.25 per cent vanillin, associated with resins, vanillic acid and sometimes anisyl alcohol and anisic aldehyde.

Manufacture of Synthetic Vanillin

Numerous patents have been granted for the manufacture of synthetic vanillin. Most of these, however, may be said to have only a nuisance value. Many depend upon the oxidation of isoeugenol to vanillin. In general it may be said that even though the hydroxyl group is protected any process in which isoeugenol is the basic material and bichromate, permanganate, etc., are used for its oxidation must necessarily fail unless steps are taken also to protect the aldehyde group as it is formed. Otherwise it will be oxidized direct to the acid.

The electrolytic oxidation of the sodium salt of isoeugenol,[1] using a double cell and a coating of lead peroxide on the anode, has been found to have no practical value, since only a trace of vanillin is formed. The isoeugenol turns into a brown resinous mass. Other difficulties are apparent when it is realized that the electrolysis is carried out in strong alkaline solution with porous diaphragms.

The use of ultra-violet rays would appear to be the simplest method for the preparation of vanillin from isoeugenol. The process consists of passing air through isoeugenol in which is immersed a light emitting ultra-violet rays. The theory of the operation is that the ultra-violet rays convert oxygen in the air to ozone and this in turn is responsible for the oxidation. It will be seen at once that the rate of oxidation depends upon the penetrating power of the ultra-violet rays, and this in turn is dependent upon the clearness of the isoeugenol. The use of distilled isoeugenol, which is much more expensive, is therefore necessary. Even starting with a very light-colored product, the oil darkens in a couple of hours so that the rate of oxidation rapidly decreases. Another difficulty in this process arises from the fact that the air must be circulated through the solution at a rate of about 30,000 cu.ft. per hour, and this causes a considerable loss of isoeugenol by vapor tension. When using 30,000 cu.ft. of air per hour on 800 lb. of isoeugenol the loss amounts to about 80 lb. in 8 hours.

Vanillin can also be made by a number of straight chemical processes, but most of them have not as yet advanced to an economical stage. One process uses protocatechuic aldehyde, but that is most difficult to obtain. Another process uses guaiacol according to Reimer's reaction. Any process using this reaction, chloroform, alkali and a phenol to introduce the aldehyde group is bound to be expensive on account of the low yield of final product. Still another process starts with a diketonic acid. This process need not be discussed excepting to say that this acid is more expensive than the final product.

There are, however, two processes both starting with isoeugenol that deserve more than passing consideration. One depends on the oxygen exchange between isoeugenol and nitrobenzol. The other process depends on the oxidation of isoeugenol to vanillin using ozone and a protecting agent for the vanillin formed. It is the writer's intention to discuss both of these process in subsequent articles on vanillin manufacture.

Art and Science of Leather Manufacture—IV

In Addition to Methods Employing Tannin, Hides and Skins May Be Converted Into Leather by Treatment With Smoke and Fat, Alum, Chromium Salts, Iron Salts, Formaldehyde, Oil and Quinone — Water Supply and Waste Disposal Important Factors in Tannery Operation†

BY F. L. SEYMOUR-JONES*

HISTORICALLY smoke and fat tannage was probably the first developed by primitive man. The action of his tent fire smoke and of grease on his skin clothing and hunting trophies must have been discovered at a very early stage in his civilization. Even today among primitive peoples such a tannage is found. The Eskimos work fat and grease into the skin by chewing and masticating it bit by bit, a slow if effective process. Such a leather also is the so-called rawhide, like the South African reims, used for harness and other purposes. The hide is cut into one long strip, and fat is worked in by twisting and untwisting it, keeping it taut by suspension from a branch and attaching a weight. The method is simple and the product has the greatest tensile strength of any leather. In fact, broadly, the more processes a hide undergoes in being turned into leather the less strength it has.

TAWING OR ALUM TANNAGE

Another old method, still largely used today for such purposes as belt laces, aprons, whip lashes, kid gloves, fine shoe leather, etc., is known as tawing. This is in reality an aluminum tannage. In the pure alum tannage the skins are soaked, or drummed in, or sponged with a solution of a basic aluminum salt and common salt. After tannage the skin is dried out, aged, then damped back and staked, either by pulling the skin over a blunt knife edge until soft, or by machine, in which a pair of jaws bearing a blunt knife and a rounded surface or roller grip the skin and pass over it. Such leather is not very resistant to water, though increasingly so on aging. In tawing proper the skins are drummed in a mixture of alum, salt, flour and egg yolk, together with a little olive oil. They are then dried, aged by storing for a month or more to fix the tannage, damped back, softened and staked. They are next washed, re-egged with yolk and salt, and dyed by brushing on. After drying they are perched - i.e., the skin is fixed to a bar and stretched on the flesh side with a moon knife. The flesh is finally fluffed by a rotating emery-covered or carborundum wheel.

Only the gluten, and not the starch, of the flour is taken up by the skin. The proteins of the yolk serve as fillings, but the oil is the most important constituent. The somewhat expensive yolk has been successfully replaced with sulphonated oils, though this is a recent innovation not yet passed into general practice.

Chrome tanning, though known as far back as 1858 to Knapp, the pioneer chemist in leather manufacture, has really developed only during the last 30 years. It has already replaced vegetable tanning in many lines (e.g., glazed kid from goatskins), has established itself in others (e.g., belting leather), and is invading even sole leather manufacture.

CHEMICAL NATURE OF CHROME LIQUORS

Chromium exhibits many valences, but it is only its trivalent salts which tan. If a liquor containing a normal chrome salt alone is used, the acid liberated by hydrolysis of the salt swells the skins unduly, and only the surface is tanned, yielding a cracky leather. Consequently basic salts of chromium are used in tanning. If too basic, tannage is extremely slow and the resulting leather thin and flat. About the best basicity to use is a liquor corresponding to a salt of $Cr(OH)SO_4$ say.

Whether the liquors are solutions of true basic salts or whether they contain hydrous chromic oxide colloidally dispersed in the solution of the normal salt, or whether again they contain chromium in a complex anion, is still somewhat of an open question. Chromic salts in solution exist in two forms, violet and green, the former preponderating in the cold and the latter on heating. The difference is more than one of color, and is explicable on the Werner theory. Thus chromic chloride, $CrCl_3.6H_2O$, ionizes differently according to its color, as shown below:

$$\underset{\text{Violet}}{(Cr.6H_2O).Cl_3} \text{ and } \underset{\text{Green}}{(CrCl_2.4H_2O).Cl.2H_2O}$$

Furthermore, green solutions are highly hydrolyzed and have a hydrogen-ion concentration about ten times that of violet solutions of corresponding strength. Solutions of chromic salts at ordinary temperatures are equilibrium mixtures of these two forms. While the change from violet to green on heating is rapid, the reverse change is slow. There appears to be very little difference in the tanning properties of green and violet solutions, but the swelling effect of the free hydrogen-ion in the green has to be taken into account.

Many tanners prefer to buy their chrome liquors in concentrated form direct from the manufacturer, who frequently obtains it as a dyeworks byproduct. In making it direct, potash alum or chromic sulphate, together with the necessary amount of soda, is often used, but more frequently sodium (or potassium) bichromate is reduced in acid solution. Passing sulphur dioxide through plain bichromate solution provides an excellent liquor. Glucose is frequently used, but care has to be taken in the reduction, as there is a possibility of the formation of hydroxy organic acids, which, with their salts, not only prevent the fixation of chromium by the hide, but can also be used to strip (remove chromium from) chrome leather. Very many other substances have been suggested and are used in reducing—e.g., bisulphites, thiosulphate, sawdust, spent tan, etc.

*Frank L. Seymour-Jones is the son of Alfred Seymour-Jones, of Wrexham, Wales, who for many years has been one of the foremost tanners of Great Britain and one of the leading scientists of the industry. Frank Seymour-Jones was graduated from the University of Leeds, England, with honors in applied chemistry of leather manufacture, being awarded the Le Blanc medal for special distinction. He now holds the Goldschmidt fellowship at Columbia University, where he is continuing fundamental research on tannery processes.

†Article I of this series appeared in *Chem. & Met.*, vol. 27, No. 23, p. 1110, Dec. 6, 1922, Article II in vol. 27, No. 26, p. 1253, Dec. 27, 1922; Article III in vol. 28, No. 5, p. 200, Jan. 31, 1923.

However the chrome liquor be prepared, it will usually contain some neutral salt, either added to it or formed during its preparation or from the salt used in pickling the skins. This materially alters the properties of the liquor. It slows up the tannage, affects the hydrogen-ion concentration and hence the swelling power, and also renders it possible to make the liquor more basic before the chromium begins to precipitate out. Hence in order to evaluate a basic chrome liquor, it is necessary to know its chromium content, basicity (amount of acid combined with one equivalent of chromium), acidity (hydrogen-ion concentration) and its neutral salt content. It is useful to test from time to time the amount of alkali necessary to bring about incipient precipitation. By adding just less than this amount to the liquor, it is possible to continue tanning, and even to finish tanning in liquors almost exhausted of chromium.

The mechanism of neutral salt action, despite much research work, is not yet thoroughly understood. Much light has been thrown upon it, but the very complicated nature of the chemistry of chromium compounds has so far prevented a clear cut solution. Hydration alone can only be a subsidiary cause, since sucrose, in concentrations up to $3M$, does not affect the tanning. Probably some compound formation comes into play.

One-Bath and Two-Bath Processes

The actual operation of one-bath chrome tanning is simple. The goods start off in a weak liquor, which is gradually strengthened as tannage proceeds. Tannage may be in drums or paddles or by suspension, the last being of course much slower, though favored for heavy hides for sole leather. When tanned, the skins are blue throughout, and are washed. One common criterion of tannage is that a piece of skin, placed in boiling water, should not shrink in size; this is known as the boiling test. After washing, the skins are neutralized, to remove nearly all free acid and to fix the chromium on the fiber in a more basic form. Weak alkalis are used for this, so that not only the surface but also the interior of the skin is properly neutralized. Borax and whiting are highly suitable. This is usually carried out in a drum.

After neutralization, light stock is set out on the table with a blunt knife to remove surplus moisture, then fat-liquored by drumming in an oil-water emulsion (usually emulsified with a little soap). Unless sulphonated oils are used, neutralization must be sufficiently thorough to remove excess acid which would otherwise break the emulsion. The fat-liquoring lubricates the fibers, renders the leather supple and pliable and increases its tensile strength. Leather which will crack on bending before fat-liquoring may be bent and stretched at will after, without any cracking of the grain. Dyeing may precede or follow the fat-liquoring.

Heavy stock for belting or sole leather is stuffed in very much the same way as for vegetable leather, except that higher temperatures may be used with safety. As chrome leather is by nature of the tannage "empty," stuffing is usually heavy, not only to add weight but also to render the leather thoroughly waterproof. Hydraulic leather (for pumps, washers, etc.) can be dipped when thoroughly dry into molten waxes and then baked in the oven to distribute and fix the grease.

Apart from the one-bath process, in which the skins are tanned in a basic chrome solution direct. the "two-bath" process is applied to certain classes of goods, particularly glazed kid. In this, reduction of the chromium from hexa- to tri-valent is brought about on the fiber itself. The skins are first treated in a bath of bichromate and hydrochloric acid, then in one of sodium thiosulphate ("hypo") and hydrochloric acid. This converts them into leather. The outstanding difference between the two methods is that in the two-bath process considerable quantities of sulphur are deposited in the skin. The sulphur softens the leather, acts as a filler and combines to some extent with the oils used in fat-liquoring. Straight sulphur tannage is possible, so that there is here probably some tanning action from the sulphur also.

Although the second (acid-hypo) bath to a large extent neutralizes the leather, it is usual to complete neutralization by drumming with borax, etc., prior to fat-liquoring and dyeing.

Finishing Chrome Leather

Finishing is complicated, and varies according to the class of leather desired. After fat-liquoring and dyeing, the skins are sammed (half dried), staked, "grained" (by rolling the skin over itself, to raise the grain pattern) or not, as required, dried out, the grain surface seasoned with an albumen-milk or gum season, and glazed by machine. The glazing machine comprises a glass or agate cylinder on an arm which presses the leather against the bed as the arm moves from the workman, lifting on the return stroke. Frequently artificial grains are embossed on, either with a plate or roller, and extremely clever imitations of the real article are so produced.

Heavy leather chrome tanned receives very little finishing, it being usually sufficient to see that it is of even color and good appearance. Any excess grease is slicked off.

Iron Tannage

Iron tannage has been attempted many times during the last 70 years, and Knapp preferred it to chrome. So far it has met with very little success. Owing to the ease with which ferric iron passes to the ferrous state and *vice versa* the destructive action of the oxygen on the skin is appreciable. Iron-tanned leathers in general are apt to crack on the grain and do not last well. So far the only place where iron tanning has been practiced on a large scale would appear to be Germany. The great shortage of vegetable tanning materials and chromium compounds in the central empires during the war years brought about much p ogress in iron tanning. But even here it was generally carried out as a combination tannage, in conjunction with chrome, formaldehyde or vegetable. The general principles of iron tannage follow those of chrome, with the necessary modifications due to its chemical nature. One difficulty with iron-tanned leather is that if tannin is to be employed as a mordant in dyeing, naturally only blacks can be used.

Many other metallic salts have been suggested for tanning. Most of them tan, but are not likely to be used on a commercial scale. They are principally those of the heavy metals; in particular may be mentioned manganese, cerium and nickel.

Use of Formaldehyde

Formaldehyde is a very efficient tanning agent, and, unlike most tanning materials. is usually used in faintly alkaline solution (around p_H 8). It produces a nice, white leather, but unless all excess aldehyde is removed,

the fiber gradually becomes brittle and tender. Excess alkali will cause the leather to rot on keeping, while excess acidity prevents complete tannage.

Chamois

Wash leather or chamois leather is made almost entirely from the flesh splits (linings) from sheepskins. The lightly drenched skins are kneaded in a fulling mill with sawdust until semi-dry. They are then sprinkled with fish oil, stocked or kneaded again, and the process is continued, with occasional pauses to permit the goods to cool, until the limy smell of the skins is replaced by a more pungent, aldehydic odor, and the skins are thoroughly saturated with oil. They are then boxed up, where, owing to the rapid oxidation of the unsaturated oils, they heat. They are taken out and cooled from time to time, and the process continued until they no longer heat and are yellow throughout, the skins then being thoroughly leathered. Much pungent acrolein vapor is evolved during oxidation. The surplus oil is pressed out from the skins (yielding moellon or degras) and further extracted with alkali, whence it is recovered by neutralization (yielding sod-oil). Degras and sod-oil are used for stuffing other types of leather. Sometimes the goods are hung up in warm stoves during oxidation.

Various kinds of fish oil are used, chiefly cod, together with seal, whale, etc. The skins are subsequently bleached, either by exposing while damp to the sun, or with permanganate or acidified sodium peroxide.

While the acrylic aldehyde formed by dehydration of the glycerin may play some part in giving the skins an aldehyde tannage, all the oils used must contain some free fatty acid. It is possible to tan skins completely with unsaturated fatty acids, containing more than two double bonds and entirely free from glycerin. Consequently a complete explanation of the mechanism of the tannage is still lacking.

Another fat tannage, intermediate between chamoising and rawhide manufacture, is used to produce "Crown" and "Helvetia" leather. In this a paste of soft fats (horse grease, tallow) and flour is worked into the skin. Occasionally oils and fish oils are also used

Quinone Tannage

One tannage, interesting theoretically, was investigated by Meunier. Pelt placed in dilute quinone solution becomes rose-colored, violet, and finally brown, being completely "leathered.' Hydroquinone is present in the final liquor, showing that the pelt had combined not only with quinone but also with oxygen. Tannage in hydroquinone solutions is also possible in presence of air, but is much slower. Similar "oxidation" tannages can be carried out with phenol and phenol derivatives (pyrogallol, gallic acid) in presence of air and preferably in weakly alkaline solution. Further, chlorine, bromine and iodine, especially the bromine, produce very satisfactorily tanned leather. The oxidation theory of tannage is largely based on these facts. Apart from some use of quinone in France, the main practical application lies in the boiling of exhausted tan liquors, whereby part of the non-tans are converted into substances capable of tanning, probably by oxidation.

Some combination tannages, using both mineral and vegetable tannage, are employed for special leathers. "Dongola" leather, a combination of alum tawing and gambier tannage, was originally produced as an imitation glazed kid. Semi-chrome leather is also largely produced. It is a very strong and durable product. Stuffed with 20 to 25 per cent of grease, it is waterproof and was largely used in army boots during the war. It is also eminently suitable for farm boots, where the alkaline liquors of the farm yard render a pure chrome tannage unsuitable. Chroming may precede or follow vegetable tanning, and may be by either the one- or two-bath process. East India kips, roughly vegetable tanned in India, have part of the vegetable tan stripped in alkali, and are then chromed. It is not possible to combine all advantages of two tannages by a combination; thus chrome leather loses much of its stretch by a vegetable retannage.

Patent Leather

Patent leather is now almost entirely chrome tanned, though a little is still manufactured by the vegetable process. The leather is tanned, staked and fat-liquored, then blacked with logwood and iron, dried and staked again. Often the leather is next degreased with benzine or naphtha. Ordinary chrome leather degreased is harsh, but degreased after fat-liquoring it remains supple and soft. After degreasing the leather is stretched out perfectly flat on lath frames. The first varnish coat is then applied by sponge and hand, being very thoroughly worked in over the grain surface. The leather is then dried by exposure to sunlight or ultra-violet light. The enameled surface is smoothed by rubbing over with a flat pumice stone, and a second coat of varnish is applied by brush. This is done in a dust-free room, next to the drying stoves, with the men stripped to the waist. A little water is sprinkled over, and the leather stoved over night. When thoroughly dry a finish is applied, a solution of nitrocellulose in amyl acetate-acetone, together with a pigment; small amounts of castor oil in the finish give durability and aid flexibility. The composition of the varnishes is largely guarded as a trade secret. Boiled linseed oil, tanked to allow the deposition of foots, is the main constituent, though tung oil is also used sometimes. As driers, manganese, lead and zinc salts are used, often the resinates. Prussian blue and lampblack serve as pigments. The oil is boiled to the desired constituency and thinned down with turpentine.

The use of nitrocellulose and collodion finishes has been extended to flesh splits (from ox and cow hides) for upholstery leather. A grain is then embossed on by machine, and a useful product obtained for automobiles, furniture, etc.

Fish Leather

Of recent years some progress has been made in the tanning of fish skins, shark, porpoise, blackfish, etc. In the case of the first the chief difficulty has been the removal of the hard shagreen, but this has now been solved by suitable treatment of the skins in acid solutions. The skins can be limed and bated if desired, and tanned by almost any of the usual processes. The fish leather industry (apart from sealskins) is still in its infancy, but promises to show great developments when the advantages and the limitations of its products are better understood.

Water Supply

In tannery control the importance of the nature of the water supply is very considerable. Apart from considerations of boiler feed water, the hardness adversely affects various processes. Temporary hard

water in washing goods after liming may cause precipitation of calcium carbonate in the grain surface, causing lime blast. In making up deliming liquors with organic acids the neutralization of the hardness by the costly organic acid is expensive. In leaching tanning materials, tannin is precipitated by the calcium bicarbonate. In dyeing, basic dyes are precipitated and dyeing is streaky. Fat liquors containing soap may be curdled by the hardness. Permanent hardness is of less importance, but is equally objectionable with fat liquors. Iron in water is highly objectionable if skins are to be vegetable tanned. Usually pipes in the leach house are made of copper or brass. Organic and much suspended matter usually points to the presence of bacteria, which are objectionable and may cause trouble in bating. Chlorides, found in water from tidal rivers chiefly, are harmful in repressing swelling and producing flat leather.

Byproducts

Byproducts from tanning are of little value. Hide and skin trimmings from the lime yard go for glue and gelatine manufacture. Hair usually finds a market, the white fetching a higher price. Colored hair goes to plasterers, for mixing in with mortar, and iron founders, for cores and loam casting. Spent tanbark is usually burned, after removal of surplus moisture by squeezing; it also occasionally finds a market for covering the earthen pots in the manufacture of white lead by the Dutch process. Scrap leather is of no value for manure, and chrome is reputedly poisonous to plants. It is usually worked up for artificial leather and leather board, or stripped and used for glue stock. Lime sludge from old limes is of some manurial value, owing to its nitrogen content.

The disposal of waste liquors from a tannery is a problem in itself, owing to their usually high bacterial content. Settling tanks and the removal of solid matter are essential. Where such liquors discharge into a stream, cases have arisen where a farmer, down stream, has sued the tanner for damages for the death of cattle from anthrax, reputedly caused by the tannery effluent.

Apart from anthrax, the only unusual sickness likely to arise in a tannery is chrome sores, which come from exposure of the hands to bichromate solutions. Where the men work alternately in the bichromate and the reducing baths, these are not likely to occur, but it is best to avoid contact of the skin with chrome liquors. Lime, and sodium sulphide still more so, in contact with the human skin attack it. Consequently lime yard workers are invariably provided with rubber or other gloves. On the whole tannery workers are an unusually healthy lot and even men working with natural puer seem to suffer no ill effects.

Conclusion

The leather trade offers an entrancing choice of problems to the scientist, bewildering in their number and complexity, but all the more fascinating on that account. The chemist cannot hope to tell the tanner how to make leather until far more is understood of the mechanism of the very diverse and varying processes. He has a useful place in control work today, and those who are capable of applying the results of research, frequently abstruse and of no apparent connection with tanning, will save their firms much time and money, while at the same time maintaining a high quality product.

Coke Shortages in Both France and Germany

Effects of the French and Belgian Occupation of the Ruhr Are Already Being Felt by Chemical and Metallurgical Industries in Both Countries

Developments in the Ruhr district are directly accountable for serious shortages of coke in both French and German steel mills and chemical plants, according to cables received by the Commerce Department from its foreign representatives. Since Jan. 15 practically no coal or coke has entered France from Germany, and the production of the Saar Basin is reported as completely stopped due to a miners' strike effective Feb. 6. The coke shortage is more severely felt than coal; and about thirty-five blast furnaces have shut down in Luxembourg, Lorraine and eastern France since the middle of January. Coke prices have increased by 40 francs per ton, and coal prices are rising. Increased quantities of coal are being imported from England, and orders for coke are being placed in Czechoslovakia. French iron producers cannot depend upon Belgian fuel, as that country now needs its production to supply its own furnaces, and the French iron and steel market is generally slowing down. The metallurgical industries in the Lyon district continue their recovery due to activity in automobiles and electrical constructions for hydraulic development, railway orders and the general pick-up of trade in specialized machines.

Although no figures have been secured on the production of coal in the Ruhr Valley, says Commercial Attaché Herring, Berlin, in a cable to the Department of Commerce, the entire output of coal in Germany during January is estimated about 25 per cent below December. Coke production improved, but was insufficient to fill the needs of industry, while the production of lignite remained unchanged.

Conditions in German Industries

The iron and steel industry complained of a shortage of coke and iron ore during January, while coal supplies were sufficient owing to a cessation of reparation shipments. The machine industries were fully occupied, while locomotive plants reported a growing dullness on account of the marked depreciation; the electrotechnical industry was busy with old orders; the textile industry showed great activity because of large purchases of raw cotton with a favorable exchange during December and subsequently the receipt of numerous foreign orders. Unsatisfactory business was reported by the leather industries, especially in the finished leather goods and stable shoes branches.

Business was brisk in the heavy chemical industry, particularly on account of big export sales; domestic consumers, however, are complaining that low export prices are causing a selling out to foreign buyers. The dye industry is less active and the immediate future is regarded as highly uncertain. The glass industry is normally occupied, but export sales are disappointing; this is partly ascribed to a revival of Czechoslovak competition. Coal supplies for the glass industry are reported especially short. Good exports are reported by the paper industry, but slackened domestic sales; part-time employment has been introduced in some of the mills. The rubber industry is dull and is encountering difficulty in obtaining raw materials as well as coal, necessitating part-time employment.

A Problem in Barrel Storage And How It Is Solved

This Article Will Show How It Can Be Done and Gives a Graphic Comparison Between the Three Most Important Good Methods of Barrel Storage

BY MATTHEW WILLIAM POTTS
Consulting Engineer, New York City

TO ILLUSTRATE the possiblities of economic storage of barrels, let us analyze a warehouse layout. Suppose the engineer has been supplied with the following data and the company desires the best, most efficient and most economical layout for the smallest expenditure of money (they always want that). The data, written as a matter of record and to avoid mistakes and omissions, might be as follows:

1. Maximum storage requirements? 6,000 bbl.
2. Products to be stored?* Chemicals.
3. Like, or assorted products? Approximately 100 different products to be stored. This number includes the different analyses of the same products.
4. What per cent of the products will be in dry form? Approximately 80 per cent.
5. What per cent of the products will be in liquid or paste form? Approximately 20 per cent.
6. What kind and size of barrels will the products be packed in? Standard 50-gal. tight barrels, 26 bilge diameter, 34 in. high, 23 in. chimb diameter.
7. How will the barrels be received? By motor trucks and railroad cars and in from 13- to 40-bbl. lots.
8. How must the materials be taken out of stock? The oldest stock must be shipped first.
9. Must each lot be shipped intact as it was received? No, the barrels will be shipped out in broken lots.
10. Is storage space plentiful or must every cubic foot be utilized? Ground area that can be used is limited, as costs are high.
11. Is there a preference as to the type of building desired? No, the building can be any type, old or new.
12. Is it necessary to take a complete physical inventory? Yes, inventory must be taken every 6 months.
13. How will the goods be shipped? By cars and motor trucks.
14. Will the building be used only as a warehouse or must other facilities be provided? Provide a main office; foremen's or clerks' offices; consolidation shipping space or platform; railroad siding; street entrance and platform for receiving goods from motor trucks.

First, then, a canvass must be made of the vicinity where it is desired to locate the warehouse and the existing buildings studied to see if they can be utilized. Often it is cheaper to move a department into a new building and use the vacated building as a warehouse. To save space we shall eliminate all the preliminary layouts made for this proposition and show only the final layout, together with a detailed discussion on the various methods of storage. Assume that after investigation of a number of buildings we locate the one shown in the drawings, which is of steel and brick construction on a lot 90x170 ft. with a roof height of 26 ft. in the clear. The building proper is approximately 80x150 ft. inside dimensions, giving a total of 12,000 sq.ft. of floor space.

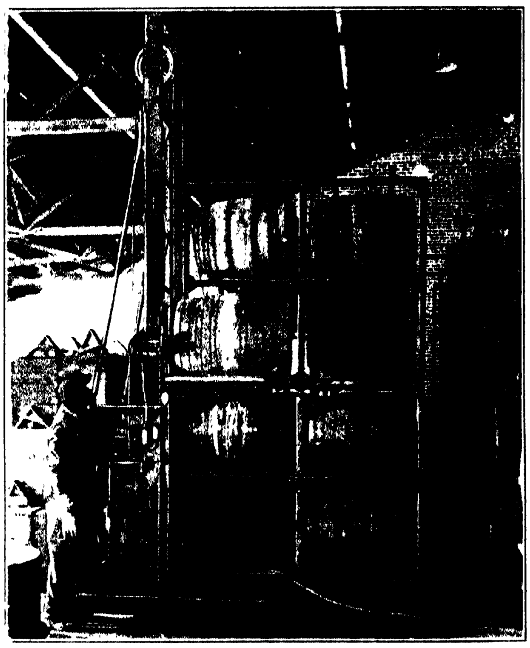

FIG. 15—THE RACK METHOD SHOWING HOW IT IS POSSIBLE TO WASH UNDER THE RACKS

The next thing to consider is the maximum storage requirements of 6,000 barrels. Of these, 4,800 barrels, or 80 per cent, will contain dry products and 1,200 barrels, or 20 per cent of the total, will contain liquids or pastes. The plan view Fig. 16 and the sectional elevation *A-A* of Fig. 17 show the possibilities of storage on the bilge using long dunnage as shown in Fig. 9. (See article by this author in *Chem. & Met.*, Feb. 14, 1923.) We find that using this method we require approximately 650 sq.ft. of floor space to store 72 barrels per tier. This area includes the side aisle necessary to get between the different rows of barrels, but does not include the area required for the main aisle. It will be noted that the side aisles are off center of the bay, which makes the odd-numbered rows contain 5 barrels per tier and the even-numbered rows 4 barrels per tier. With dry products we can tier the barrels 4 high, as shown, making 20 barrels in the odd-numbered rows and 16 barrels in the even-numbered rows, or a total of 288 barrels in 650 sq.ft. of floor area if every barrel space is filled. On the basis of these figures, to store 4,800 barrels of dry products we should require 16.6 such spaces. We still have 1,200 barrels of liquids or pastes which cannot be piled over 2 high. Under these limitations 144 barrels can be placed in 650 sq.ft. of floor area. We therefore must provide 8.3 spaces to our 16.6 spaces, making a total of 24.9 spaces for storage. In addition we must add 10 per cent for empty spaces brought about by the variety of products stored; this addition of 2.4 spaces brings the grand total to 27.3 spaces, each containing 650 sq.ft. and 650 sq.ft. $\times$ 27.3 spaces = 17,745 sq.ft. of floor area for stor-

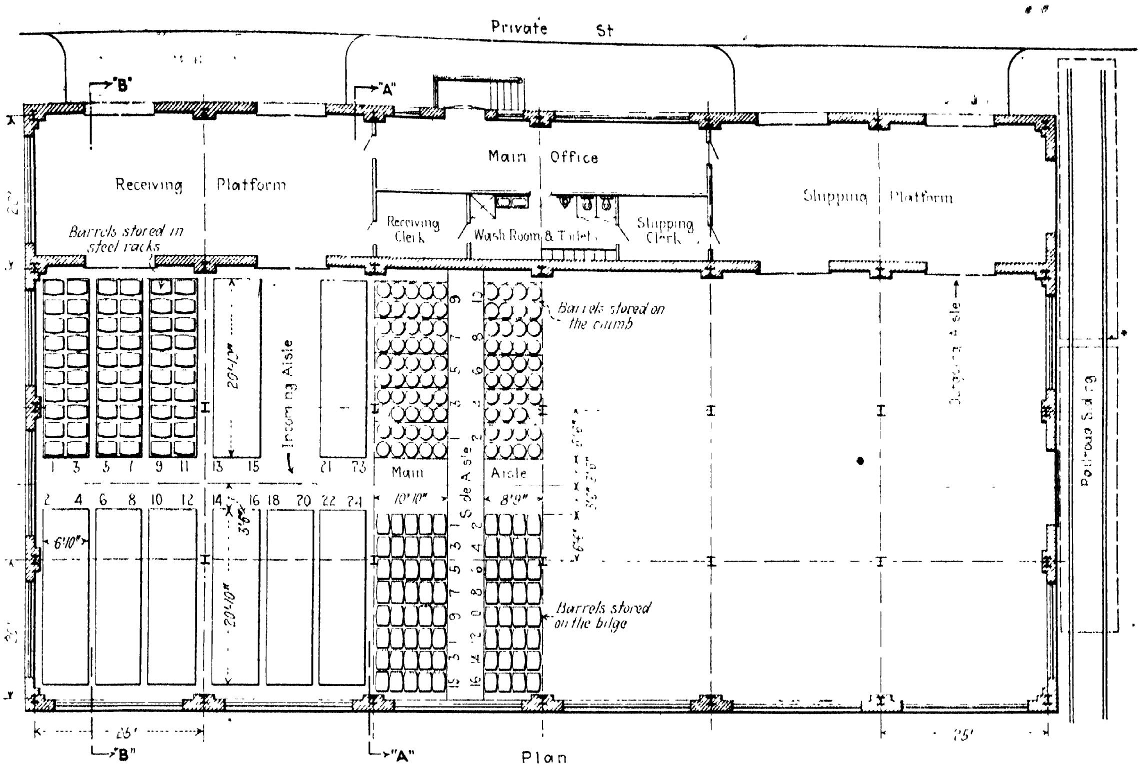

FIG 16—PLAN SHOWING LAYOUT OF BARREL STORAGE

age alone. To this must be added space for main aisles, receiving and shipping platforms, offices, etc.

Chimb Storage With Short Dunnage

In considering the method of storing barrels on the chimb it is recommended that short dunnage be used, instead of long dunnage. It has been found by the writer that by using short dunnage the lumber dunnage bill is reduced to a minimum—in fact, the same lumber has been used for from 1 to 3 years. The use of short dunnage has many advantages. First, it is not so easily broken; second, it can be easily stored in the warehouse when not in use; third, it allows the barrels to be taken down working back from the aisle. What is meant by short dunnage, the size to use and how to use it are shown in Fig. 19.

Referring to plan view Fig. 16 and the sectional elevation *A-A* of Fig. 17, we have a graphic representation of how to store barrels on the chimb. We find that it requires approximately 650 sq.ft. of floor space to store 90 barrels per tier. This floor area includes the same as in the previous method. When using the chimb method of storage we cannot figure a row as one barrel wide, because the barrels are more difficult to place and the man must work on all sides of the barrel until he gets it into position. We therefore plan the rows two barrels wide, the even-numbered rows containing 8 barrels per tier and the odd-numbered rows 10 bar-

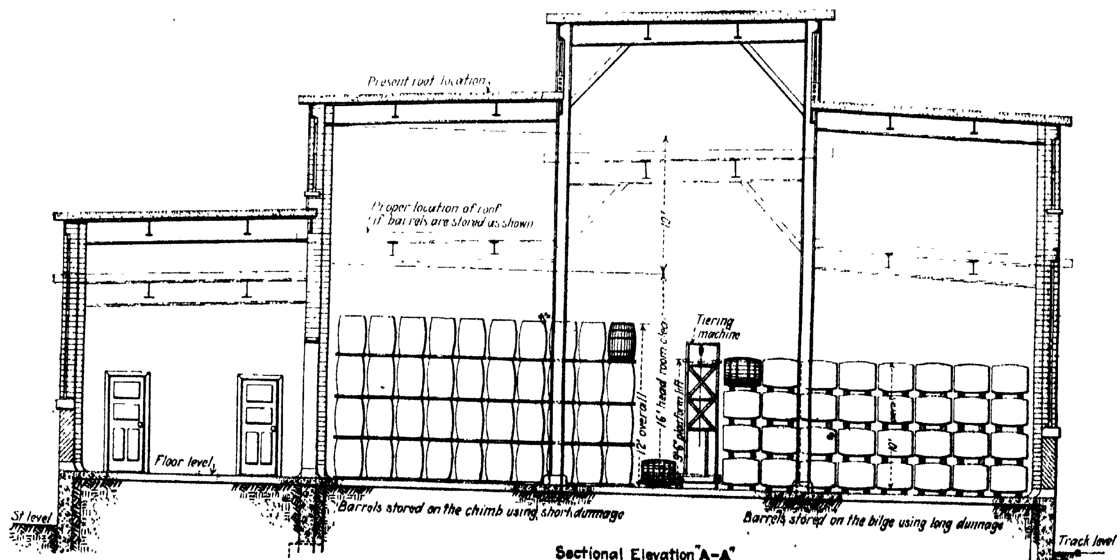

FIG. 17—SECTIONAL ELEVATION AT "A-A" IN FIG. 16

rels per tier. The barrels containing dry products can be tiered 4 high, as shown, so we are able to place 32 barrels in the even-numbered rows and 40 barrels in the odd-numbered rows, or a total of 360 barrels in 650 sq.ft. of floor area if every barrel space is filled. On the basis of these figures, to store 4,800 barrels of dry products we should require 13.3 such spaces. We still have 1,200 barrels of liquids or pastes which must not be piled over 2 high on the bilge. We must therefore provide 8.3 spaces for these liquids or pastes, which when added to our 13.3 spaces for dry products makes a total of 21.6 spaces for storage. In addition we must add 10 per cent for empty spaces brought about by the variety of products stored. This addition of 2.1 spaces brings the grand total 23.7 spaces each containing 650 sq.ft.: 650 sq.ft. × 23.7 spaces = 15,405 sq.ft. of floor area for storage alone. To this must be added space for main aisles, receiving and shipping platforms, offices, etc.

Rack Storage

Most Economical Method for Space Utility

The rack method of barrel storage is shown in plan view, Fig. 16, and section elevation *B-B* of Fig. 18 With the rack system the barrels are all stored on the bilge, and all barrels, whether they contain liquid or dry products, are treated alike, because each barrel is supported by the rack independently, so the height of the pile or the number of tiers is not limited. Approximately 650 sq.ft. of floor area is required to store 60 barrels per tier. This includes space enough between sets of racks so that a man can walk between to inspect the barrels or take inventory. Each row, whether odd or even, contains 10 barrels per tier. The barrels are tiered 10 high, as shown, making a total of 600 barrels in 650 sq.ft. of floor area if every barrel space is filled. On the basis of these figures, to store 6,000 barrels we should require 10 spaces each containing 650 sq.ft. To this we must add 10 per cent for empty spaces brought about by the variety of products stored. This addition of 1 space brings the grand total to 11 spaces: 650 sq.ft. × 11 spaces = 7,150 sq.ft. of floor area for storage alone. To this must be added space for main aisles, receiving and shipping platforms, offices, etc.

The following tabulation compares the three methods:

Method of Storage	Floor Area for Storage Alone, Sq.Ft.
On the bilge with long dunnage...	17,745
On the chimb with short dunnage.	15,405
In steel racks....................	7,150

This shows that for a given area more barrels can be stored per square foot with the rack system than with other methods.

Looking at this problem from another angle, we find that the building we have selected will be large enough to store the following number of barrels under each method:

Method of Storage	Barrels Liquids	Dry	Total
On the bilge with long dunnage...	576	2,304	2,880
On the chimb with short dunnage..	576	2,880	3,456
In steel racks..........	1,200	5,600	6,800

These figures demonstrate that while the building is large enough to take care of our total requirements if we use the rack system, it would be capable of containing only approximately 50 per cent of our needs if either of the other methods were used. The more floor area required for storage the more main aisle, incoming and outgoing aisle space will have to be allowed. The space for receiving and shipping platforms, offices, etc., is the same with either method.

It was stated that the cost of land and rentals was high. This is true in almost every case. If it is necessary to build a new building, the cost is dependent upon the number of floors to be provided and the number of square feet per floor. It is at this point—namely, in the building of new warehouses to provide storage—that it is possible to save considerable money by using the rack system. In the case of old buildings it is sometimes difficult to prove that the rack system will save money, because the limiting head room does not permit the racks to be over 3 tiers high, but even here if the number of barrels handled is large enough, a material saving in the labor cost will be effected by installing racks which may offset the initial cost.

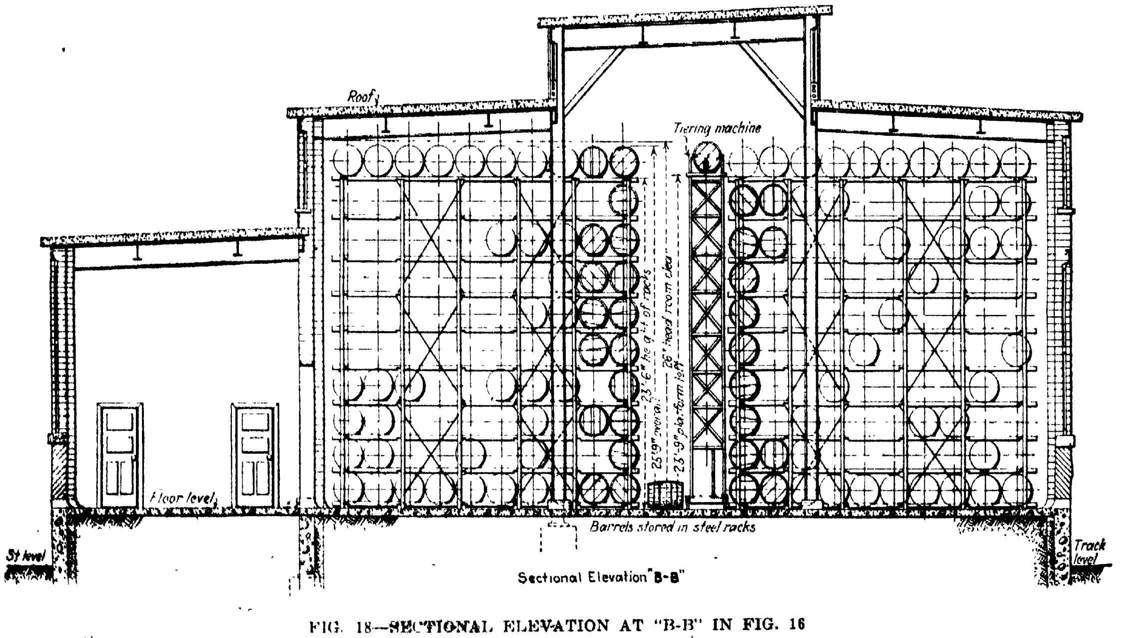

FIG. 18—SECTIONAL ELEVATION AT "B-B" IN FIG. 16

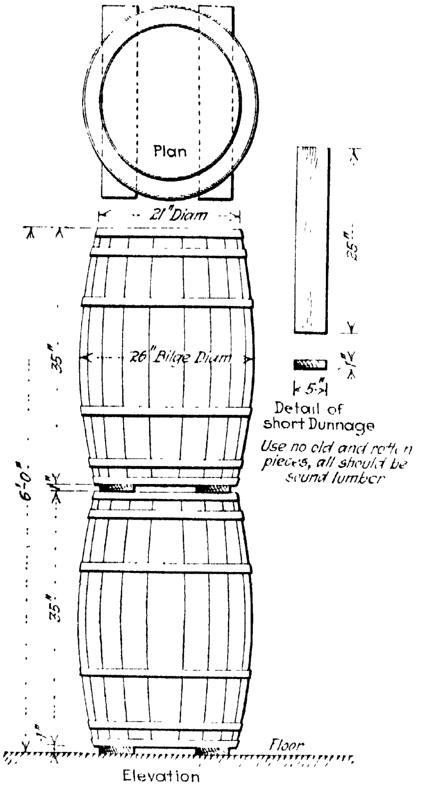

FIG. 19 DIAGRAM SHOWING USE OF SHORT DUNNAGE WHEN STORING BARRELS ON THE CHIMB

We all know that new buildings cost considerable money and this cost is in proportion to the size of the building. The cost of the building site is also dependent upon the size of the building. Taking the problem which we have just analyzed and considering a new building, it will be clearly seen that either bilge or chimb method of storage would require a building twice as large, in ground area, as the one shown, but not so high. The only comparison to make then is: Would it be cheaper to build the larger but lower building? Or would it be cheaper to build the smaller but higher building and equip it with racks? It is a simple engineering problem.

It is of no use to build a high building unless the overhead space can be used. In the storage of barrels, using either the method of piling on the bilge or on the chimb with dunnage, the maximum height of piling recommended is 4 tiers. In order to accommodate this height of pile the building would have to have at least 16 ft. in the clear. With the rack system it is possible to pile the barrels from 10 to 12 tiers high. Selecting the 10 high racks, we should require a building with 26 ft. in the clear. Thus by increasing the side walls and columns 10 ft. and installing racks we are able to reduce the floor area by more than one-half.

A Physical Inventory Must Sometimes Be Made

The complete physical inventory is something that must be considered. The requirements call for a physical inventory every 6 months. To take a physical inventory if barrels are stored on the bilge or chimb with dunnage is impossible without moving each barrel. The complete handling of 6,000 barrels is expensive and difficult; it would also require quite a lengthy shut-down of the plant. With the rack system, if the inventory tags are placed on the heads of the barrels, it is possible for one man to take an inventory of the above stock in 2 days without moving a barrel. In order to facilitate the taking of an inventory the manufacturer of the racks provides brackets on the side of the rack upon which boards are fastened, making a walkway for the man at every second tier.

When installing racks in chemical warehouses there are a few points to remember: First, always install the racks on raised piers as shown in Fig. 15. This makes it easy to wash out beneath the racks in case a barrel or drum should burst and it prevents the acid from attacking the bottom cross members; second, always paint the racks with acidproof paint. They should also be repainted at least once a year.

In conclusion, it might be said that the only satisfactory method of barrel storage is the rack system. This is true up to a certain point and applies chiefly to new warehouses. As previously stated, each installation or problem has to be considered separately. It can be added, however, that every chemical plant in the country can afford to spend a little time and money in looking over its present methods of handling, buying, filling, painting, storing and shipping of barrels. It will be found in many cases that thousands of dollars can be saved without one cent's worth of investment and that thousands more can be saved if a little money is spent in making improvements and installing the latest and most modern equipment.

Some Comparative Statistics on Glass Manufacture in 1919 and 1921

Although it might be regarded as ancient history, nevertheless the comparison between 1919 and 1921 is most enlightening. It should be remembered in studying these figures that 1921 was a year of great depression in the glass industry. It is all the more striking, therefore, that the total quantity of plate glass and of wire glass was greater in 1921 than in 1919. All of the rest of the individual commodities, such as window glass, obscured glass, pressed and blown glass, bottles and jars, showed a diminution in quantity produced of from 10 to 50 per cent.

COMPARATIVE SUMMARY, 1921 AND 1919

	1921	1919	Per Cent of Decrease
Number of establishments	328	371	11 6
Persons engaged	59,705	83,656	28.6
Proprietors and firm members	50	60	
Salaried employees	4,979	6,076	18 1
Wage earners (average number)	54,676	77,520	29 5
Salaries and wage payments	$78,852,000	$100,891,000	20.9
Salaries	12,290,000	13,364,000	8.0
Wages	67,562,000	87,527,000	22 8
Contract work	131,000	241,000	45.6
Cost of materials	86,883,000	90,780,000	4 3
Value of products	212,593,000	261,384,000	18 8
Value added by manufacture	125,710,000	171,104,000	26.5

Lime-Sulphur Concentrate

The U. S. Department of Agriculture Farmers' Bulletin 1285 describes methods and apparatus for the preparation and use of lime-sulphur solutions and the lime-sulphur concentrate, which are so extensively used as an insecticide and fungicide. The circular, which is available on application to the Department of Agriculture, Washington, D. C., describes a wide variety of apparatus for home manufacture of this material. The apparatus ranges in size from a simple 25-gal. kettle to steam plants in which 800 gal. of concentrate can be prepared in a single cooking.

Fundamentals of Rectification

The Conditions for Reversible Rectification

With Certain Assumptions as to the Properties of Mixtures It Is Shown That Low-Temperature Separations Can Be Carried Out in Such a Way That the Minimal Work Necessary Is Equal to the Theoretical Minimal Work by Means of Ideal Semi-Permeable Membranes*

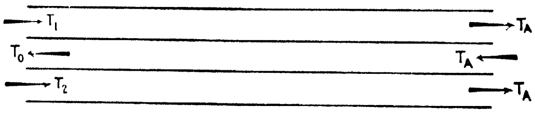
By C. C. Van Nuys
Chief Physicist, Air Reduction Co., New York City

WE SHALL now undertake a general investigation of the conditions existing in an ideal rectification system when all the transformations accomplished therein are thermodynamically reversible.

In any thermodynamic process a necessary and sufficient condition for reversibility is that, during any transformation, equilibrium conditions are maintained throughout—e.g., if a heat transfer occurs, it must be between bodies having only infinitesimal differences of temperature, or if a fluid does work by exerting pressure, that pressure must at any instant be the true equilibrium pressure corresponding to the volume and temperature of the fluid at rest at that instant. Therefore, if we impose the condition that rectification shall be accomplished reversibly, it will be necessary to make the compositions of liquid and vapor in contact at any point in the column to be those compositions for phase equilibrium. That is to say, x and y anywhere in the column at the same level must have the relation for phase equilibrium.

In what follows we shall have occasion to determine not only the conditions existing in the rectification column proper when this relation is maintained but we shall also endeavor to calculate the work necessary to produce these conditions reversibly and to determine the relation between this work and the theoretic minimal work of separating the constituents of a binary mixture by means of the well-known ideal device of semi-permeable pistons. In order to avoid uncertainties connected with the pressure-volume-temperature relations for an imperfect gas, the theoretic minimal work of separation of the constituents of a fluid mixture is generally calculated under conditions such that both the mixture and its separated constituents may be assumed to have the properties of a perfect gas. Since, however, when the separation is accomplished by rectification, the mixture generally enters the column in a condition approaching that of saturated vapor or of liquid, while the separated products generally leave the rectifier in the saturated vapor state, it will be necessary to inquire into the ways and means available for producing these conditions.

Whenever a binary mixture of two constituents whose liquefaction temperature is considerably below atmospheric is separated by liquefaction and rectification, it is the general practice to employ the cold separated products to cool down the incoming mixture entering the column as much as possible in a so-called countercurrent heat interchanger; that is, an apparatus in which the cold outgoing products are in as intimate thermal contact as possible with the incoming unseparated mixture. Considered from the most general point of view, we may say that what an interchanger is designed to accomplish is the taking of heat from an incoming mixture and transfering it as nearly reversibly as possible to the cold outgoing separated products. In general, it is impossible to cause this transfer to take place in the interchanger reversibly, even though we assume perfect insulation from outside heat effects and perfect thermal conductivity between the incoming and outgoing streams, unless certain relations hold between masses and total heats of those streams. This relation we shall proceed to obtain.



In the first place, if we assume that no external heat enters or leaves the interchanger, the "total heat" of all fluids entering the interchanger must equal the total heats of all fluids leaving, since no external work is performed in the apparatus. Second, if we assume that the masses of all fluids entering equals that of fluids leaving, the heat capacity of the entering mixture must be the same as for the outgoing products at the same temperature, since otherwise the temperature of the ingoing fluid could not be equal everywhere to that of the outgoing fluid in thermal contact with it and thus there would rise irreversibility of heat transfer in the interchanger. Even though this last condition is not satisfied, we may still suppose the exchange to be accomplished reversibly without the expenditure of external work, provided that the difference of "total heat" of the ingoing mixture between the initial temperature T_A at which it enters the interchanger and the temperature T_0 at which we wish it to leave the interchanger is equal to the sum of the increases of "total heat" for the separated products between the temperatures T_1 and T_2 at which we wish them to enter the interchanger and the fundamental temperature T_A. The ideal reversible process by which this could be accomplished is as follows:

Let the mass of incoming mixed fluid of temperature T_A entering the system per unit time be m_A and suppose that we wish to lower its temperature to T_0 by transferring the necessary heat to two separated products coming from the rectification apparatus, one of mass m_1 at temperature T_1 and the other of mass M_2 at temperature T_2, the temperature of both these fluids being brought ultimately to the value T_A. Assume that we have a reversible Carnot engine working first between m_A and m_1, transferring heat from the former to the latter until the temperature of m_1 is T_A, and let us calculate the work expended upon this engine.

Let the temperature of m_A at some instant be T, and its specific heat at that temperature be C, and suppose the temperature of m_1 at that instant is τ_1. Let the quantity of heat Cm_AdT be taken from m_A. The

*The first four articles in this series were published in the issues of Jan. 31 and Feb. 7, 14 and 21, 1923.

fraction of this which is transformable to work in a Carnot engine working between T and τ_1 is $\frac{T-\tau_1}{T} Cm_A dT$, and the heat imparted to m_1 will be $\frac{\tau_1}{T} Cm_A dT$. Let this process continue until the fluid m_1 has the temperature T_A, and let T_3 be the final temperature of m_A. The total heat taken from m_1 during this process will be

$$+\int_{A}^{3} Cm_1 dT$$

The total work expended will be

$$-\int_{A}^{3} \frac{T-\tau_1}{T} Cm_1 dT$$

and the total heat imparted to m_1 will be

$$+\int_{A}^{3} \frac{\tau_1}{T} Cm_1 dT$$

Now let the Carnot engine begin to discharge heat into M_2, instead of m_1, the instantaneous temperature thereof bening τ_2. Then by hypothesis, when the final temperature of M_2 is T_1, that of m_1 will be T_0. The heat taken from m_1 during this part of the process will be

$$+\int_{3}^{0} Cm_1 dT$$

The total work expended will be

$$-\int_{3}^{0} \frac{T-\tau_2}{T} Cm_1 dT$$

and the total heat imparted to M_2 will be:

$$\int_{3}^{0} \frac{\tau_2}{T} Cm_1 dT$$

Hence if the total work expended during the whole process is zero, we have:

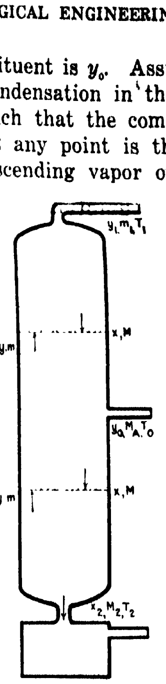
$$-\int_{T_A}^{T_3} \frac{T-\tau_1}{T} Cm_A dT - \int_{3}^{0} \frac{T-\tau_2}{T} Cm_A dT = 0$$

or

$$\int_{A}^{0} Cm_A dT = \int_{A}^{3} \frac{\tau_1}{T} Cm_T dT + \int_{3}^{0} \frac{\tau_2}{T} Cm_A dT$$

That is, the change of total heat of the incoming mixture must be equal to that of the outgoing products, if it be possible to accomplish the exchange reversibly without expenditure of work.

Now assume that we are dealing with a binary mixture which has the property that its difference of total heat between the saturation point and the temperature T_A at which it enters the interchanger is equal to the sum of the differences of the total heats of the separated products each one between saturation and the temperature T_1 at which it leaves the interchanger. For such a mixture, then, we may assume that the work necessary to change the condition of the incoming mixture reversibly from the initial temperature down to the saturation point, by permitting the separated products in the saturated condition to be restored to the initial temperature, is zero, and we may assume that the incoming unseparated fluid enters the rectification column in the saturated condition and each outgoing separated product leaves the rectification column in the saturated condition. Let us suppose that a mass m_A of such a mixture at temperature T_0 enters an intermediate level of a rectification column and that its composition in the more condensible constituent is y_0. Assume that by a system of distributed condensation in the upper half we attain a condition such that the composition x of the descending liquid at any point is that for phase equilibrium with the ascending vapor of composition y at that level. Let the absolute temperature at which the incoming mixture centers, and also the absolute temperature at which the outgoing products leave the interchanger, be T_A.



Let us suppose that the condensation in the upper half of the column is produced by an infinite series of reversible Carnot engines, each one of these engines working between one level in the column and atmospheric temperature. Thus, any Carnot engine working at the level where the composition of liquid is x takes the heat required to condense the mass dM of liquid necessary to be condensed at that level and rejects this heat, together with the heat equivalent of the necessary work, at the temperature T_A. Assume that the vaporization necessary in the lower half of the column is also produced by an infinite series of Carnot engines, each one of these taking in an amount of heat at temperature T_1, such that the heat rejected at a lower level x in the column is such as to produce the amount of evaporation necessary at that level. Suppose that a mass m_1 of composition y_1 of a saturated vapor leaves the top of the rectification column and that a mass M_2 of liquid of composition x_2 is drawn from the bottom of the column. Then the total work necessary to be expended in order to produce the products m_1 and M_2 will be the algebraic sum of the work expended in the whole series of Carnot engines, this series including not only those working as described in the column proper, but those necessary to evaporate the mass M_2 of liquid to saturation.

First consider the level (x, y) in the upper part of the column. Let the mass of liquid descending at this point per unit time be M and its composition x, and the mass of vapor ascending per unit time at the same level be m and its composition y. Then we have the three following equations among x, y, y_1, M, m and m_1:

$$m = M + m_1$$
$$ym = xM + y_1 m_1$$
$$y = F(x)$$

where the function F denotes the relation for constant pressure between the compositions x and y of liquid and vapor in phase equilibrium for the particular mixture treated.

From the first two equations we obtain:

$$M = \frac{y - y_1}{x - y} m_1$$

Considering the column as a whole, we have:

$$m_A = m_1 + M_2$$

and

$$y_0 m_A = y_1 m_1 + x_2 M_2$$

from which

$$m_1 = \frac{x_2 - y_0}{x_2 - y_1} m_A$$

and hence for any M above the level of inlet of m_A we have:

$$M = \frac{y - y_1}{x - y} \frac{x_2 - y_0}{x_2 - y_1} m_A$$

Next consider a level (x, y) in the lower half of the column. Here we have

$$M = M_2 + m$$

$$xM = x_2 M_2 + ym$$

and

$$y = F(x)$$

where F is the same function as before.

From the first two equations we obtain:

$$M = \frac{x_2 - y}{x - y} M_2$$

but from equations for column as a whole

$$M_2 = \frac{y_0 - y_1}{x_2 - y_1} m_A$$

Whence, for any M in the lower part of the column,

$$M = \frac{x_2 - y}{x - y} \frac{y_0 - y_1}{x_2 - y_1} m_A$$

If, for the mixture dealt with, the form of the function F were known, y or x could be eliminated from the two equations we have obtained for M, and thus the value of M obtained as a function of y or x, and by differentiation of this function it would be possible to obtain the derivatives $\frac{dM}{dx}$ or $\frac{dM}{dy}$ in terms of x or y and the constants x_2, y_0, etc.

As an example, consider a mixture for which the latent heat, L, at constant pressure for all compositions follows the proportionality law as indicated by the equation

$$L = L_B x + L_A (1 - x)$$

For such a system, we have shown above that a functional relation between the compositions x and y of liquid and vapor in phase equilibrium which satisfies the conditions is given by

$$\frac{y}{1 - y} = a \frac{x}{1 - x}$$

Eliminating x between this equation and the equation obtained above, giving the value of M in the upper part of the column, we have:

$$M = \frac{(y - y_1)[y + a(1 - y)]}{(1 - a) y (1 - y)} \frac{x_2 - y_0}{x_2 - y_1} m_A$$

By differentiation of this equation, we obtain:

$$\frac{dM}{dy} = \frac{y^2(1 - y_1) + a y_1 (1 - y)^2}{(1 - a) y^2 (1 - y)^2} \frac{x_2 - y_0}{x_2 - y_1} m_A$$

Now, if the quantity dM of liquid be condensed at the level (x, y), the heat necessary to be removed at that point in the column will be:

$$\frac{d(LM)}{dy} dy$$

Let us suppose that the absolute temperature at this level in the column is T. Then the work required to absorb this heat at temperature T by a reversible Carnot engine, and reject it at the initial temperature, will be:

$$\frac{T_A - T}{T} \frac{d(LM)}{dy} dy$$

and the total work necessary to be expended in the upper part of the column will be

$$W_1 = \int_{y_1}^{y_0} \frac{T_A - T}{T} \frac{d(LM)}{dy} dy$$

or

$$W_1 = \int_{y_1}^{y_0} \frac{T_A - T}{T} \left(L \frac{dM}{dy} + M \frac{dL}{dy} \right) dy$$

But if we substitute the value of x from

$$\frac{y}{1 - y} = a \frac{x}{1 - x}$$

in the equation

$$L = L_B x + L_A (1 - x)$$

it becomes

$$L = \frac{L_B y + L_A a (1 - y)}{y + a(1 - y)}$$

and

$$\frac{dL}{dy} = \frac{(L_B - L_A) a}{[y + a(1 - y)]^2}$$

whence

$$\frac{d(LM)}{dy} = L \frac{dm}{dy} + M \frac{dL}{dy} = \frac{x_2 - y_0}{(1 - a)(x_2 - y_1)} \left[\frac{L_B (1 - y_1)}{(1 - y)^2} + \frac{L_A a y_1}{y^2} \right] m_A$$

Substituting this in the expression for W_1, we have:

$$W_1 = m_A \int_{y_1}^{y_0} \frac{T_A - T}{T} \frac{x_2 - y_0}{(1 - a)(x_2 - y_1)} \left[\frac{L_B (1 - y_1)}{(1 - y)^2} + \frac{L_A a y_1}{y^2} \right] dy$$

In the lower half of the column, we have:

$$M = \frac{x_2 - y}{x - y} \frac{y_0 - y_1}{x_2 - y_1} m_A$$

Eliminating x as before, we obtain:

$$M = \frac{(x_2 - y)[y + a(1 - y)]}{(1 - a) y (1 - y)} \frac{y_0 - y_1}{x_2 - y_1} m_A$$

Differentiating this equation, we have:

$$\frac{dM}{dy} = - \frac{y^2 (1 - x_2) + a x_2 (1 - y)^2}{(1 - a) y^2 (1 - y)^2} \frac{y_0 - y_1}{x_2 - y_1} m_A$$

Now, if at the level (x, y) a quantity of liquid $- dM$ be evaporated, the heat required will be $- \frac{d(LM)}{dy} dy$. The work obtained from a Carnot engine working reversibly between the temperature T_A and the temperature T at this point, when said engine rejects the above amount of heat at temperature T, is

$$\frac{T_A - T}{T} \frac{d(LM)}{dy} dy$$

Hence, the total work obtained in the lower part of the column, including that obtained by the evaporation of the liquid M_2, will be

$$W_2 = - \int_0^{y_2} \frac{T_A - T}{T} \frac{d(LM)}{dy} dy + \frac{T_A - T_2}{T_2} [L_B x_2 + L_A (1 - x_2)] M_2$$

where T_2 is the temperature of the liquid M_2

In this case, we have:

$$M = \frac{(x_2 - y)[y + a(1 - y)]}{(1 - a) y (1 - y)} \frac{y_0 - y_1}{x_2 - y_1} m_A$$

$$\frac{dM}{dy} = - \frac{y^2 (1 - x_2) + a x_2 (1 - y)^2}{(1 - a) y^2 (1 - y)^2} \frac{y_0 - y_1}{x_2 - y_1} m_A$$

from which

$$\frac{d(LM)}{dy} = L\frac{dM}{dy} + M\frac{dL}{dy} =$$

$$-\frac{y_0-y_1}{(1-a)(x_2-y_1)}\left[\frac{L_B(1-x_2)}{(1-y)^2}+\frac{L_A a x_2}{y^2}\right] m_A$$

Substituting this value, W_2 becomes:

$$W_2 = m_A\int_{y_0}^{y_2}\frac{T_1-T}{T}\,\frac{y_0-y_1}{(1-a)(x_2-y_1)}\left[\frac{L_B(1-x_2)}{(1-y)^2}+\frac{L_A a x_2}{y^2}\right]dy$$

$$+ m_A\frac{T_A-T_2}{T_2}\,\frac{y_0-y_1}{x_2-y_1}[L_B x_2 + L_A(1-x_2)]$$

Hence, the total work expended in the whole system is

$$W_1 - W_2 = \int_{y_1}^{y_0}\frac{T_1-T}{T}\,\frac{d(LM)}{dy}\,dy + \int_{y_0}^{y_2}\frac{T_1-T}{T}\,\frac{d(LM)}{dy}\,dy - \frac{T_1-T_2}{T_2}[L_B x_2 + L_A(1-x_2)]M_2$$

while the net amount of heat removed from the column is

$$\int_{y_1}^{y_0}\frac{d(LM)}{dy}\,dy + \int_{y_0}^{y_2}\frac{d(LM)}{dy}\,dy - [L_B x_2 + L_A(1-x_2)]M_2$$

Now, since the heat taken from the fluids in the upper part of the column is equal to that added in the lower part, the latter expression must vanish while the expression for total work expended should be equal to the theoretic minimal work of separation, W_m, since all transformations in the system, including those in the interchangers, have been made reversible. Hence we have the two equations:

$$\int_{y_1}^{y_0}\frac{d(LM)}{dy}\,dy + \int_{y_0}^{y_2}\frac{d(LM)}{dy}\,dy - [L_B x_2 + L_A(1-x_2)]M_2 = 0$$

and

$$T_A\left\{\int_{y_1}^{y_0}\frac{d(LM)}{T\,dy}\,dy + \int_{y_0}^{y_2}\frac{d(LM)}{T\,dy}\,dy - \frac{[L_B x_2 + L_A(1-x_2)]M_2}{T_2}\right\} = W_m$$

Substituting the above values of $\frac{d(LM)}{dy}$ and M, these expressions become:

$$\frac{x_2-y_0}{1-a}\left[L_B(1-y_1)\int_{y_1}^{y_0}\frac{dy}{(1-y)^2}+L_A a y_1\int_{y_1}^{y_0}\frac{dy}{y^2}\right]$$

$$-\frac{y_0-y_1}{1-a}\left[L_B(1-x_2)\int_{y_0}^{y_2}\frac{dy}{(1-y)^2}+L_A a x_2\int_{y_0}^{y_2}\frac{dy}{y^2}\right]$$

$$-(y_0-y_1)[L_B x_2 + L_A(1-x_2)] = 0$$

and

$$\frac{x_2-y_0}{1-z}\left[L_B(1-y_1)\int_{y_1}^{y_0}\frac{dy}{(1-y)^2T}+L_A a y_1\int_{y_1}^{y_0}\frac{dy}{y^2T}\right]$$

$$-\frac{y_0-y_1}{1-a}\left[L_B(1-x_2)\int_{y_0}^{y_2}\frac{dy}{(1-y)^2T}+L_A a x_2\int_{y_0}^{y_2}\frac{dy}{y^2T}\right]$$

$$-\frac{(y_0-y_1)[L_B x_2 + L_A(1-x_2)]}{T_2} = K$$

where

$$K = \frac{W_m(x_2-y_1)}{m_A T_A}$$

Integrating the first equation, we obtain:

$$\frac{x_2-y_0}{1-a}\left(\frac{L_B}{1-y_1}+\frac{L_A a}{y_0}\right)$$

$$-\frac{y_2-y_0}{1-a}\left(\frac{L_B}{1-y_0}\,\frac{1-x_2}{1-y_2}+\frac{L_A a x_2}{y_0 y_2}\right)$$

$$-[L_B x_2 + L_A(1-x_2)] = 0$$

But since

$$\frac{y_1}{1-y_1} = a\frac{x_2}{1-x_2},$$

$$\frac{x_2}{y_1} = \frac{a x_2 + 1 - x_2}{a}$$

and

$$\frac{1-x_2}{1-y_1} = a x_2 + 1 - x_2$$

Hence:

$$\frac{x_2-y_0}{1-a}\left(\frac{L_B}{1-y_0}+\frac{L_A a}{y_0}\right)$$

$$-\frac{a x_2 - y_1(a x_2 + 1 - x_2)}{1-a}\left(\frac{L_B}{1-y_0}+\frac{L_A}{y_0}\right)$$

$$-[L_B x_2 + L_A(1-x_2)] = 0,$$

which is identically true—i.e., the method may be employed whatever be the composition, y_0, of the mixture treated or whatever be the compositions y_1 and x_2 of the separated products.

The second equation, giving the work of separation, is:

$$\frac{x_2-y_0}{1-a}\left[L_B(1-y_1)\int_{y_1}^{y_0}\frac{dy}{(1-y)^2T}+L_A a y_1\int_{y_1}^{y_0}\frac{dy}{y^2T}\right]$$

$$-\frac{y_0-y_1}{1-a}\left[L_B(1-x_2)\int_{y_0}^{y_2}\frac{dy}{(1-y)^2T}+L_A a x_2\int_{y_0}^{y_2}\frac{dy}{y^2T}\right]$$

$$-\frac{(y_0-y_1)[L_B x_2 + L_A(1-x_2)]}{T_2} = K$$

In this equation T may be regarded as a function of T_1, T_2, y, a, K, L_A, L_B, which has the property that $T = T_1$ when $y = 0$, and $T = T_2$ when $y = 1$.

This relation may be expressed in the symbolic form

$$\frac{T - T_1}{T_2 - T} = f(y, T_1, T_2, a, K, L_A, L_B)$$

where f is a function such that when $y = 0$ its value is zero, and when $y = 1$ its value is ∞. Assume, for example, that the form of the function is $\frac{by}{1-y}$ where b is a constant whose values depends upon those of T_1, T_2, a, K, L_A, L_B. If this were the relation between y and T, we should have the equation:

$$\frac{T - T_1}{T_2 - T} = \frac{by}{1-y}$$

The value of T from this equation being then substituted in the second integral equation, y would be the only variable therein contained, and said equation would become integrable, the result after integration being an equation to determine the value of the constant b in terms of T_1, T_2, a, K, L_A, L_B. The value of T as determined by the relation assumed between T and y is

$$T = \frac{bT_2 y + T_1(1-y)}{by + 1 - y}$$

If this value be substituted in the integral equation under discussion, it becomes:

$$\frac{x_2-y_0}{1-a}\left\{L_B(1-y_1)\int_{y_1}^{y_0}\frac{(by+1-y)\,dy}{(1-y)^2[bT_2y+T_1(1-y)]}+L_Aay_1\int_{y_1}^{y_0}\frac{(by+1-y)\,dy}{y^2[bT_2y+T_1(1-y)]}\right\}$$
$$-\frac{y_0-y_1}{1-a}\left\{L_B(1-x_2)\int_{y_0}^{y_2}\frac{(by+1-y)\,dy}{(1-y)^2[bT_2y+T_1(1-y)]}+L_Aax_2\int_{y_0}^{y_2}\frac{(by+1-y)\,dy}{y^2[bT_2y+T_1(1-y)]}\right\}$$
$$-\frac{(y_0-y_1)[L_Bx_2+L_A(1-x_2)]}{T_2}=K$$

In the first integral, let:

$$\frac{by+1-y}{(1-y)^2[bT_2y+T(1-y)]}=\frac{A}{(1-y)^2}+\frac{B}{1-y}+\frac{C}{bT_2y+T_1(1-y)}$$

Clearing of fractions and equating like powers of y on both sides of the equation, we obtain the three following equations to determine A, B and C.

$$AT_2+BT_2+C=1$$
$$AbT_2-AT_1+BbT_2-2BT_1-2C=b-1$$
$$-BbT_2+BT_1+C=0$$

from which

$$A=\frac{1}{T_2}$$
$$B=\frac{T_2-T_1}{bT_2^2}$$
$$C=\frac{(T_2-T_1)(bT_2-T_1)}{bT_2^2}$$

Thus the first integral reduces to

$$\frac{L_B(x_2-y_0)(1-y_1)}{1-a}\left[\frac{1}{T_2}\int_{y_1}^{y_0}\frac{dy}{(1-y)^2}+\frac{T_2-T_1}{bT_2^2}\int_{y_1}^{y_0}\frac{dy}{1-y}+\frac{(T_2-T_1)(bT_2-T_1)}{bT_2^2}\int_{y_1}^{y_0}\frac{dy}{bT_2y+T_1(1-y)}\right]$$

Integrating and simplifying, this becomes:

$$\frac{L_B(x_2-y_0)(1-y_1)}{1-a}\left[\frac{y_0-y_1}{T_2(1-y_0)(1-y_1)}+\frac{T_2-T_1}{bT_2^2}\log_e\frac{1-y_1}{1-y_0}+\frac{T_2-T_1}{bT_2^2}\log_e\frac{bT_2y_0+T_1(1-y_0)}{bT_2y_1+T_1(1-y_1)}\right]$$

In like manner the third integral reduces to

$$-\frac{L_B(y_0-y_1)(1-x_2)}{1-a}\left[\frac{y_2-y_0}{T_2(1-y_2)(1-y_0)}+\frac{T_2-T_1}{bT_2^2}\log_e\frac{1-y_0}{1-y_2}+\frac{T_2-T_1}{bT_2^2}\log_e\frac{bT_2y_2+T_1(1-y_2)}{bT_2y_0+T_1(1-y_0)}\right]$$

In the second integral, let

$$\frac{by+1-y}{y^2[byT_2+(1-y)T_1]}=\frac{A}{y^2}+\frac{B}{y}+\frac{C}{byT_2+(1-y)T_1}$$

Clearing of fractions and equating like powers of y as before, we obtain

$$A=\frac{1}{T_1}$$
$$B=-b\frac{T_2-T_1}{T_1^2}$$
$$C=\frac{b(T_2-T_1)(bT_2-T_1)}{T_1^2}$$

Thus, the second integral reduces to:

$$\frac{L_Aay_1(x_2-y_0)}{1-a}\left[\frac{1}{T_1}\int_{y_1}^{y_0}\frac{dy}{y^2}-b\frac{T_2-T_1}{T_1^2}\int_{y_1}^{y_0}\frac{dy}{y}+\frac{b(T_2-T_1)(bT_2-T_1)}{T_1^2}\int_{y_1}^{y_0}\frac{dy}{bT_2y+T_1(1-y)}\right]$$

Integrating and simplifying, this becomes:

$$\frac{L_Aay_1(x_2-y_0)}{1-a}\left[\frac{1}{T_1}\left(\frac{1}{y_1}-\frac{1}{y_0}\right)-b\frac{T_2-T_1}{T_1^2}\log_e\frac{y_0}{y_1}+\frac{b(T_2-T_1)}{T_1^2}\log_e\frac{bT_2y_0+T_1(1-y_0)}{bT_2y_1+T_1(1-y_1)}\right]$$

In like manner the fourth integral reduces to:

$$-\frac{L_Aax_2(y_0-y_1)}{1-a}\left[\frac{1}{T_1}\left(\frac{1}{y_0}-\frac{1}{y_2}\right)-b\frac{T_2-T_1}{T_1^2}\log_e\frac{y_2}{y_0}+\frac{b(T_2-T_1)}{T_1^2}\log_e\frac{bT_2y_2+T_1(1-y_2)}{bT_2y_0+T_1(1-y_0)}\right]$$

Now let us assume that the products m_1 and M_2 are the pure components completely separated; then $x_2=1$, and $y_1=0$. Substituting these values in the above integrated expressions, and remembering that when $x_2=y_2=1$,

$$\frac{1-x_2}{1-y_2}=a,$$

the equation for the separation work becomes:

$$\frac{L_B}{(1-a)T_2}\left[y_0+(1-y_0)\frac{T_2-T_1}{bT_2}\log_e\frac{bT_2y_0+T_1(1-y_0)}{T_1(1-y_0)}\right]$$
$$-\frac{L_By_0(1-x_2)}{1-a}\left[\frac{1}{T_2(1-y_2)}+\frac{T_2-T_1}{bT_2^2}\log_e\frac{1-y_0}{1-y_2}\right]$$
$$+\frac{L_Aay_1(1-y_0)}{1-a}\left[\frac{1}{T_1y_1}-b\frac{T_2-T_1}{T_1^2}\log_e\frac{y_1}{y_0}\right]$$
$$-\frac{L_Aay_0}{(1-a)T_1}\left[\frac{1-y_0}{y_0}+b\frac{T_2-T_1}{T_1}\log_e\frac{bT_2y_0}{bT_2y_0+T_1(1-y_0)}\right]$$
$$-\frac{L_By_0}{T_2}=K$$

Evaluating for the limits as $y_1=0$, $x_2=1$,

$$\frac{L_By_0}{(1-a)T_2}+\frac{L_B(1-y_0)}{1-a}\frac{T_2-T_1}{bT_2^2}\log_e\frac{bT_2y_0+T_1(1-y_0)}{T_1(1-y_0)}-\frac{L_Bay_0}{(1-a)T_2}-\frac{L_Aay_0}{1-a}b\frac{T_2-T_1}{T_1^2}\log_e\frac{bT_2y_0}{bT_2y_0+T_1(1-y_0)}-\frac{L_By_0}{T_2}=K$$

or

$$\frac{L_B(1-y_0)}{bT_2^2}\log_e\frac{bT_2y_0-T_1(1-y_0)}{T_1(1-y_0)}+\frac{L_Aaby_0}{T_1^2}\log_e\frac{bT_2y_0+T_1(1-y_0)}{bT_2y_0}=\frac{(1-a)K}{T_2-T_1}$$

Although we have assumed the functional relation between y and T in the above calculations, the result exhibits the limitations which any functional relation between T and y must possess for a mixture having the properties we have assumed.

Table I shows the values obtained for x, y and T by Baly (*loc. cit.*) for mixtures of oxygen and nitrogen with the corresponding computed values of a and b. The table shows that b is fairly constant for all values of y, while a increases somewhat with increasing values of y.

Taking as an average value, $b=1.58$, we shall calculate a from the equation last written. In this equation:

$$K=\frac{W_m}{T_Am_A}$$

where

$$W_m=PVy_0\log_e\frac{1}{y_0}+(1-y)\log_e\frac{1}{1-y_0}$$

TABLE I

90 96	100 00	100 00					

Now assume as a particular case $y_0 = \frac{1}{2}$, then the work equation becomes:

$$\frac{L_B}{bT_2^2}\log_e\frac{bT_2+T_1}{T_1}-\frac{L_Aab}{T_1^2}$$

$$\log_e\frac{bT_2+T_1}{bT_2}=\frac{2(1-a)PV\log 2}{(T_2-T_1)m_AT_A}$$

Taking $V = 1$ c.c., and assuming that

$$L_A = 47.85$$
$$L_B = 51.2$$
$$P = 1 \text{ atmosphere}$$
$$T_A = 273.13$$

then $m_AT_A = 0.00134 \times 273.13 = 0.366$, and

$$\frac{2PV\log_e 2}{(T_2-T_1)m_AT_A}=\frac{2\times 76\times 13.59\times 981\times 0.6931}{13.42\times 0.00134\times 273.13\times 4.184\times 10^7}=0.00682$$

Substituting these values and solving for a, we obtain:

$$a = 0.222$$

Bearing in mind the several assumptions which we have made in regard to the properties of the mixture considered in the above theory which are not exactly true for oxygen and nitrogen, and considering also the probable inaccuracies, particularly of temperature measurement in Baly's experimental work, the above result may be regarded as very satisfactory.

Employing this value of a, and taking $y = 20.8$, we find for the composition x of the liquid having phase equilibrium with air,

$$x = 0.542$$

This result thus seems to support the probability, already suspected as a result of experimental work performed under the direction of Dr. Harvey N. Davis at Harvard University, that Baly's values of co-existing phase compositions are somewhat too close together.

SUMMARY

The purpose in undertaking the foregoing calculation was, first of all, to determine whether processes of low-temperature separations of mixed gases involving liquefaction and rectification may ideally be carried out in a reversible manner—i.e., in such a way that the minimal expenditure of work necessary to accomplish the result by such methods is equal to the theoretical minimal work of separation by means of the ideal device of semi-permeable pistons. While the calculation as actually performed is based upon one or two simplifying assumptions in regard to the properties of the mixture treated, the result is such as to show clearly that rectification can actually be accomplished in a manner approaching thermodynamic reversibility and indicates the main features that must characterize such a process under these conditions, even though the mixture treated does not possess the simple properties assumed for the one studied above.

The value of considerations of reversibility in any process wherein economy of energy expenditure is desirable can scarcely be overestimated. In the development or improvement of any process, the engineer should constantly bear in mind that perfect efficiency is attained when and only when the various transformations, compressions, expansions, heat transfers or what not are perfectly reversible. When these conditions are not met to the highest possible degree, we may be certain that we have attained the highest possible thermodynamic efficiency. We must remember, however, that in order for rectification to be accomplished, irreversible conditions between the liquid and vapor in contact at all levels in the rectifier is necessary to a degree and that the more nearly we approach reversibility in this respect the slower will be the rectification. A similar statement, of course, may be made in regard to all thermodynamic transformations—these transformations are possible only by reason of the existence of irreversible conditions of one kind or another. This being the case, true economy in any process should be sought by endeavoring so to adjust the various irreversibilities therein in such a manner that the sum total of the available energy dissipated by reason of these irreversibilities is a minimum, these adjustments being carried to the point where further economy of available energy would be neutralized by increased cost of equipment and of operation of the apparatus necessary to accomplish that economy.

British Gas Statistics

The *Gas Journal* (London) summarizes the latest statistics regarding the British gas industry in its issue of Jan. 31, 1923. The totals given in this summary are for Great Britain—England, Scotland, and Wales. The bulk of the sales are coal gas or water gas, but the small amount of "Other Gas" included relates to plants making semi-water gas, carburetted hydrogen, producer gas, peat gas, gasoline gas or acetylene gas used in city distribution systems. The quantities of coal gas recorded include some coke-oven gas produced for distribution either alone or mixed with other kinds of gas.

	1921	1920
No. of companies	797	758
Materials Used:		
Coal carbonized (tons)	15,775,696	17,566,316
Coke for water gas	1,254,122	....
Oil (gal.)	51,731,492	....
Gas Made:		
Coal gas (M.cu ft.)	194,518,147	214,703,118
Water gas (M.cu ft.)	49,894,716	36,932,530
Other gas (M.cu.ft.)	4,606,869	5,342,096
Total	249,019,732	256,977,744
Coke and Byproducts Made:		
Coke and breeze (tons)	10,404,702	....
Tar (gal.)	160,376,472	....
Ammonium sulphate (tons)	115,979	....

Ordinary	3,488,090	3,417,685
Length of mains (miles)	39,547½	38,847

Synopsis of Recent Chemical & Metallurgical Literature

Utilizing Rubber Latex in Paper Making

The use of rubber latex for manufacturing purposes is rapidly gaining recognition. The practical effect of its application in industry will result in the further co-ordination of the rubber and other industries, according to a writer in the *India Rubber World* for February. The first successful application of rubber latex relates to the improvement of paper as regards strength. Two methods have been followed in utilizing rubber latex for paper making—viz., the beater method and a new method known as top sizing. The former method, patented by Frederick Kaye, is fairly well known. It consists of adding the rubber latex, well diluted, to the beater pulp. The amount of latex varies with the quality of the fiber. Experiments with partly beaten fiber made into hand sheets with and without latex indicate that the bursting strain and folding number of the latex paper were much above those of paper made under exactly similar conditions without latex.

Unfortunately, however, American paper manufacturers have not met with great sucess in the use of latex with the beater method. The element of uncertainty in this difficult method has led to the discovery of a simpler and surer process. This is known as the "top sizing method," and consists of top sizing with latex, containing a minimum of 30 per cent pure rubber. After the paper has been immersed in a top sizing mixture of latex and casein, it is run between rolls to squeeze out the excess liquid and to insure an even distribution on the surface. The paper is then dried on moderately heated rolls. The latex-casein mixture consists of 75 per cent latex and 25 per cent water-soluble casein, calculated on a basis of dry rubber and casein, diluted with equal volumes of water. After dipping and drying, or partial drying, the paper may be subjected to a dilute formaldehyde bath, which tends to increase the water resistance. The top sizing process is also applicable in making paper for wrapping, insulating, oil- and water-resistant purposes. Experiments have already been made with kraft paper and the favorable results indicate quite clearly the value to the industry of such a process.

Rotary Kiln Lime Burning

EDITOR'S NOTE:—This is an abstract of an informal talk before the National Lime Association in June, 1922. Rotary kiln operation in the lime industry is likely to be a significant factor in the future and the author's wide experience gives to these remarks a considerable prestige. It is published in the *Proceedings* of the National Lime Association.

From the cement manufacturer many data have been obtained on physical problems such as structural strength of kilns, dry burning, feeding devices, etc., but many new problems were encountered. Progress has been slow because there is only one unit with which to experiment and deviations from practice which gives fairly good results are consequently conservative.

Fuel

Kilns may be fired with either producer gas or pulverized coal and although the author's experience has been only with producer gas, he believes pulverized coal will work excellently and intends to install a unit. Mechanical gas producers give a much more even gas and have made possible an increase in production from 90 tons per day to 110 tons per day with a lime-coal ratio of over 3. (This is on a 6½ ft. inside diameter by 150 ft. long kiln.)

Size of Stone

Material is sized through a 1½-in. screen and retained on a ⅝-in. mesh. Experience seems to indicate that the kilns like small stone, but there is a practical limit to the sizing. Considerable difference of opinion exists as to whether the fines or coarse particles are more difficult to burn. The author's experience indicates that operating conditions will determine this. The fines will ride in the center of the kiln if it is overloaded, whereas in a thinner load with rapid passage of material the larger pieces are apt to have an unburned core. The latter case is more frequently met in practice.

Kiln Loading and Speed

A definite ratio between kiln loading and speed should be maintained. The depth of the load should be kept constant and the rate of burning controlled by variation in kiln speed. An increase in heat is apt to be dangerous because of the danger of fluxing and sticking of the charge especially with dolomitic lime. An additional control is exercised by changing the angularity of the wheels under the cool end, which controls the travel in the kiln. The author believes that ½ in. per foot is the best inclination, though he uses ¾ in. Greater speed can be obtained at a smaller angle. Heat recovery is out of the question on a single unit. With two units the investment might pay.

Dusting in the limekiln is very difficult to control and very essential to control, for dusting effectively damps the burning flame. The control must be exercised at the discharge end, for at the charging end the rock is non-pulverent.

In order to recover some heat from the lime it is usually run through a rotary cooler. The best design of this apparatus is in inserting quadrant partition plates. This divides the charge into four units and cuts down the dusting. Z-bars are worse than useless, as they pick up the lime and drop it through the air. This makes dusting a great nuisance.

The rotary kiln has very high capacity and an interchange of ideas will doubtless lead to a great improvement in efficiency of operation.

Important Articles in Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department, but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

Recent Chemical & Metallurgical Patents

Determination of Naphthalene in Gas—W. H. Fulweiler has assigned to the U.G.I. Contracting Co. his patent for quantitative determination of naphthalene in illuminating gas. In the practice of the invention the naphthalene content of the gas is converted into naphthalene picrate by passing a known quantity of gas through a standard solution of picric acid, thereby increasing the electric resistance of the solution. The value of the electric resistances of the treated and of the standard solutions are then compared, thereby estimating quantitatively the naphthalene content of the gas. (1,443,330. Jan. 23, 1923.)

Artificial Fuel—Christian I. Gillstrap has devised the process of forming an artificial fuel of ground lignitic material, ground clay, ground commercial coke and a tar binder which is processed by coking the mixture at 500 to 1,000 deg. C. His patent also covers the product which is defined as "an artificial fuel consisting of a mixture of 2,000 parts of crushed lignitic material, 20 parts of coal tar, 100 parts of ground clay, and 40 parts of ground commercial coke mixed together and heated to effect coking." (1,443,359. Jan. 30, 1923.)

Process of Making Coke Briquets—W. E. Davies, of London, England, is granted a patent on a special process of coke-briquet making which is intended to meet the difficulty which he describes as "the tendency for the briquet to suffer disruption so that no practical coke is produced." He describes the process as follows: "A process of making coke in briquetted form which consists in first mixing the coal or reinforcing its pre-existent natural binding material with up to 10 per cent of its weight of a resinous binder, then compressing the coal to form briquets which are perforated, bored or the like to increase their surface, and then carbonizing or partly gasifying the briquets under a pressure maintained below that of the atmosphere, substantially as described." (1,443,618. Jan. 30, 1923.)

Crusher—Milton F. Williams has patented and assigned to the Williams Patent Crusher & Pulverizer Co. a new form of crusher. There are two new and interesting features to this crusher, which follows in general the familiar rotary hammermill type. The first is a breaker plate which may be adjusted toward or away from the hammer circle to suit the degree of fineness of the material being crushed. The second is an adjustable bottom to the crusher feed-hopper, by means of which the rate of feeding can be varied at will, or changed to suit the angle of repose of various substances which might be crushed. (1,439,781. Dec. 26, 1922.)

Nickel Alloy—This invention comprises the addition to the customary Monel metal alloy of an excess of aluminum over that usually employed, so that the total amount of aluminum shall constitute from 8 to 10 per cent of the total contents of the alloy.

It is claimed that with this amount of aluminum the metal becomes so hard that it cannot be cut with a hacksaw or filed, and if an attempt to file it is made, it turns the teeth of the file. On the other hand, the metal, while so hard, is tough and extremely resistant to shock, which makes it of value in construction. It also retains the ability of standard Monel metal to resist corrosion. Tests have shown that an addition of aluminum in percentages in excess of 17 per cent produces a brittle alloy. (1,439,865. Leon Cammen, assignor to the International Nickel Co. Dec. 26, 1922.)

Method of Producing Fine Powders—W. K. Lewis, of Newton, Mass., has assigned to the Goodyear Tire & Rubber Co. a patent for production of fine powders. In the case of zinc oxide, for example, if zinc vapors are led into diffusion or oxidizing chamber directly from retorts and burned with air, one would imagine that a very fine degree of subdivision would be obtained. As the particles agglomerate to large degree, this is not the case. The author prevents this agglomeration by adding a diluting gas, in this case carbon dioxide. The particles thus do not have an opportunity to form aggregates at the high temperature of crystallization. (1,442,285. Jan. 16, 1923.)

American Patents Issued Feb. 13, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,444,773—Soap Flaker and Distributor. Walter C Bellows, Montreal, Que., Canada, assignor to Arthur Finestone, Montreal.

1,444,802—Chemical Compound Isopropylallylbarbituric Acid. Ernst Preiswerk, Basel, Switzerland, assignor to the Hoffmann-La Roche Chemical Works, New York.

1,444,833—Apparatus for Obtaining Potash From Distillery Waste by Burning the Same. Carl Haner, Jr, Baltimore, Md., assignor to U. S Industrial Alcohol Co.

1,444,844—Making Emulsions. Karl P. McElroy, Washington, D. C., assignor to Robeson Process Co., New York.

1,444,865—Process for Treating Rubber and Products Obtained Thereby. Charles E. Bradley, Montclair, and Sidney M. Caldwell, Leonia, N J., assignors to the Naugatuck Chemical Co., Connecticut.

1,444,887—Method of Producing Pure Iron by Electrolysis. August Schwiete, assignor to the firm Chemische Fabrik Griesheim-Elektron, Frankfort-on-the-Main, Germany.

1,444,891—Method for Making Acid-Proof Alloys. Richard Walter, Dusseldorf, Germany.

1,444,956—Method of Sizing Paper. Judson A De Cew, New York, N. Y, assignor to Process Engineers, Inc.

1,444,989—Process of Obtaining Sodium Dekaborate from Boronatrocalcite. Wilhelm Voss, assignor to Schott & Gen, Jena, Germany.

1,444,997—Apparatus for the Electrical Separation of Suspended Material From Gases. Evald Anderson, Berkeley, Calif., assignor to International Precipitation Co., Los Angeles, Calif.

1,445,004—Method of and Apparatus for Solidifying Materials. Edwin Cowles, Auburndale, Mass., assignor to the Electric Smelting & Aluminum Co., Inc., Lockport, N. Y.

1,445,082—Method of Manufacturing Anhydrous Metallic Chlorides. Bernard Howard Jacobson, Charleston, W. Va., assignor to E. C. Klipstein & Sons Co., New York.

1,445,162—Apparatus for Converting Formates Into Oxalates. Herman W. Paulus, Richmond Hill, N Y., assignor to Royal Baking Powder Co.

1,445,167—Process for the Manufacture of Phosphate Manures. Hermann Plauson, Hamburg, Germany.

1,445,168—Process for the Manufacturing of Vinyl Halides. Hermann Plauson, Hamburg, Germany.

1,445,303—Method of and Means for Producing Pure Liquid Hydrocyanic Acid. William G Dingle, Los Angeles, Calif.

1,445,329—Method of Effecting Solution of Substances and Removing Coatings From Bodies. Victor Lenher, Madison, Wis.

1,445,331—Compound of Mon-Azo Dyestuffs and Lakes Derivable Therefrom. Arthur Linz, New York, N. Y., assignor to the Chemical Foundation, Inc.

1,445,366—Method of Producing Zinc Oxide. Earl P. Stevenson, Cambridge, Mass., assignor to Arthur D. Little, Inc., Cambridge, Mass.

1,445,378—Ammonia Dynamite. Clifford A. Woodbury, Media, Pa., assignor to E. I. du Pont de Nemours & Co., Wilmington, Del.

1,445,382—Manufacture of Acetose. Joe Olgierd Zdanowich, London, England.

1,445,387—Coated Paper and Substance for Coating the Same. Henry N. Case, Oak Park, Ill, assignor to Sears, Roebuck & Co, Chicago.

1,455,438—Apparatus for Treating Hydrocarbons. Stephen Louis Gartlan, Toronto, Ont., Canada, assignor of fifty-five one-hundredths to Albert Edward Gooderham, Toronto.

1,445,495—Process for Rendering Chlorides of Ketones Soluble by Means of Alkalis. Antoine Regnouf De Vains, Miribel, Ain, France.

1,445,544—Process for the Manufacture of Crotonic Acid From Crotonaldehyde. Theodor Odinga, Basel, Switzerland, assignor to Elektrizitätswerk, Lonza, Gampel, Switzerland.

1,445,603—Treatment of Sulphite Cellulose Liquors. Jacob S Robeson, Pennington, N. J., assignor to J. S Robeson, Inc., Wilmington, Del.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Proposed Dye Tariff Rules

Tentative Draft for Import Regulations for Dyes Issued as Basis for Criticism—Treasury Department Desires All Suggestions for Changes Prior to March 1

IN accordance with paragraphs 27 and 28 of the new tariff act, the Treasury Department has issued a preliminary draft of regulations for the entry and appraisement of dyes and coal-tar products. This is to serve as a basis for criticism by importers, manufacturers and others interested; and suggestions for changes to be embodied in the final draft will be received up to March 1.

The tentative draft follows:

Taking Samples Prior to Entry. An importer may be permitted under proper supervision to take samples prior to entry of articles dutiable under paragraphs 27 and 28, and appraising officers may take samples of such articles when deemed necessary.

Information Required Prior to Entry or Appraisement. An importer shall furnish to the appraising officer prior to entry or prior to appraisement such information as such officer may request

Determination of Similar Competitive Articles. A domestic article shall be considered a similar competitive article as compared with an imported article if, in the use or uses which constitute a major portion of the quantity of the imported article consumed in the United States, said domestic article accomplishes results substantially equal to those accomplished by the imported article when used in substantially the same manner.

A domestic article, which is not freely offered for sale but the predominant use of which is for the manufacture of another similar competitive domestic article, shall be considered a similar competitive article as compared with an imported article which is or may be used for the same purpose as the domestic article.

Lists of Competitive and Non-Competitive Articles. The United States appraisor of merchandise at New York shall issue at once a list of articles which he deems competitive and non-competitive, respectively, and shall from time to time add articles thereto or remove articles therefrom, as investigation and experience shall justify. Such lists shall be advisory only. The appraiser shall furnish copies of such list and amendments thereof to the Customs Information Exchange for circularization to other appraising officers and shall furnish copies thereof to the public upon request. Appraising officers shall not furnish any information regarding the American selling price or the United States value of any article named in such lists, but may upon request furnish importers with the names and addresses of all the known domestic manufacturers of or dealers in any such articles.

Entry of Articles on the Competitive or the Non-Competitive List. In entering articles named on such lists importers must state the value thereof, bearing in mind the provision in section 489 of the tariff act of 1922 that "Duties shall not, however, be assessed upon an amount less than the entered value" with the exception specified in the rest of this section of the act.

Entry of Articles on Neither the Competitive Nor the Non-Competitive List. When an article offered for entry is not named on either the competitive or the non-competitive list, the appraiser shall proceed immediately to determine to which list the article belongs, pending which determination the importer may withhold formal entry. The appraiser shall inform the importer of his determination of the question, but shall not furnish the importer with any advice regarding the value of the merchandise, though the appraiser may upon request furnish the importer with the names and addresses of all the known domestic manufacturers of or dealers in any such articles.

Difference in Strength of Imported and Domestic Articles. When an imported article is of substantially different strength from a domestic product which is deemed a similar competitive article, the value of the imported article shall be adjusted in relation to the selling price of the domestic product in accordance with the proportion which the strength of the imported articles bear to that of the domestic.

Similar Competitive Domestic Articles Which Are Not Freely Offered for Sale in the United States in the Same Condition as the Foreign Article When Imported. When a similar competitive article manufactured or produced in the United States is not freely offered for sale in the United States in the same condition as the foreign article when imported, the ad valorem rate on the latter shall, nevertheless, be based on the American selling price of the former, but such selling price shall be the price that the manufacturer, producer or owner would have received in a *bona fide* sale, or was willing to receive for such merchandise when sold in the usual course of trade and in the usual wholesale quantities, at the time of exportation of the imported article. In ascertaining the price that the manufacturer, producer or owner would have received, the appraiser shall use all reasonable ways and means in his power, which, in the opinion of the department, may properly include consideration of the cost of production, the relation of the article to any completed article of which it forms a part, or the selling price of similar articles, according to the circumstances of the particular case.

Sand-Lime Brick Association Holds Annual Meeting

The Sand-Lime Brick Association held its nineteenth annual convention at Grand Rapids, Mich., on Feb. 8 and 9, 1923. The meeting was very well attended, and the general tone was extremely optimistic. Almost every member reported difficulty in making enough brick to meet the demand a situation very unusual for this time of year. They are facing the opening of the spring building season with no stock on hand.

The program contained many interesting papers, dealing with technical problems, equipment, labor and transportation. Among the papers were some of particular interest; as Robert Marshall on "Influence of Lime in Cement Mortar," I. G. Toepfer on "Use of a Rod Grinding and Mixing Mill," "High Labor Turnover," by J. M. Zander, and "Common Labor Shortage," by W. H. Crume. An inspection was made of the plant of the Grande Brick Co.

The officers elected for the coming year were: President, J. Morley Zander, Saginaw, Mich.; vice-president, H. W. Terry, Toronto, Canada; secretary, J. S. Palmer, Sebewaing, Mich.; treasurer, Allen G. Walton, Hummelstown, Pa.; executive committee: Frank Waterman, Toronto, Canada; Irvin G. Toepfer, Milwaukee, Wis.; H. S. North, New Brunswick, N. J.; W. H. Crume, Dayton, Ohio; W. J. Carmichael, Willoughby, Ohio.

Ascertainment of American Selling Price When the Domestic Similar Competitive Article Is Offered for Sale Under Conditions Indicating an Intent to Restrain Foreign Trade. When the appraising officer shall be satisfied, after due investigation, that a similar competitive article is manufactured by only one manufacturer in the United States, or that there is a combination of manufacturers or dealers by reason of which such article is offered for sale at an arbitratry and unreasonable price which does not secure *bona fide* sales and operates to prevent importations of the imported article, such officer shall ascertain the price that the manufacturer, producer or owner would have received, within the meaning of section 402(f) of the tariff act of 1922 in *bona fide* sales, attention being invited to regulation 8 herein. All such cases shall be reported to the department with a view to their being referred to the Federal Trade Commission.

Where There Are Two or More Corresponding Domestic Products. Where there are two or more corresponding domestic products, the American selling price of the domestic product which compared with the foreign product accomplishes results more nearly equal shall be taken as the basis for assessment of the ad valorem rate; provided, however, that due allowance in price shall be made for any difference in concentration or strength between the domestic and the foreign product.

Articles Which Are Not Coal-Tar Products. The words "similar competitive articles" in paragraphs 27 and 28 shall not be construed as relating exclusively to coal-tar products. An imported coal-tar product may be compared with a domestic non-coal-tar product, or an imported non-coal-tar product dutiable under paragraphs 27 and 28 with a domestic coal-tar product, for the purpose of determining whether they are similar competitive articles. The rule provided in paragraphs 27 and 28 for the determination of similar competitive articles and the regulations herein provided thereunder, shall be applied in such cases.

Ascertainment of United States Value. The following instructions for the ascertainment of United States value are reproduced from Treasury Decision No. 39297 of Oct. 31, 1922:

Tests. Tests which are necessary in the appraisement of imported articles shall be made under conditions approximating as closely as practicable the conditions under which the articles will be actually used in trade or manufacture.

Trade Papers as Sources of Information. Appraising officers may consult the trade papers, but the weight to be given to the quotations and other information therein is for the determination of the officers themselves.

Information Required at Ports Other Than New York. Appraising officers at ports other than New York when in doubt on any question arising under paragraphs 27 and 28 shall take the question up direct with the appraiser at New York, who shall give his advice as promptly as possible. If the inquiring appraiser shall be dissatisfied with the advice of the appraiser at New York, or the latter shall be in doubt on the inquiry, the question shall be submitted to the department for an expression of its views.

Nation Will Fight Weevil

National Campaign Formed to Carry On Fight—Calcium Arsenate the Crux of the Battle

As A result of the meeting held in Atlanta, Ga., on Feb. 20-21, by interested parties, a campaign was incorporated under the laws of Tennessee to carry on a 5-year war of extermination against the boll weevil. Dr. Miller Reese Hutchison of New York is the president and managing director.

Under the plan of organization adopted, Dr. Hutchison will be the active head of the corporation, with full executive power, and will appoint a board of directors consisting of one man from each state in the cotton belt and prominent men in the cotton industry in the North and South. The directors of the cotton states will, in turn, appoint committees of five, of which they will be chairmen, to carry on the work in their respective states.

All phases of the work were considered by the various speakers at the meeting. Among others, D. B. Bradner, chief chemist of the United States Chemical Warfare Service, explained the experiments being conducted by the government in the use of poisonous gases to combat the evil. He said so far the tests had been very good.

Another feature of the meeting was the discussion of the threatened shortage of calcium arsenate, by Howard Armbruster, New York, Bradley Stoughton, New York, and Guy E. Currier.

Armbruster's Speech

Mr. Armbruster said in part:

Consideration of this subject to be comprehensive and of real value must include the demand [for calcium arsenate]. Seriously we must admit that until this question of the demand for calcium arsenate is more definitely indicated than at present there can be no true solution of the calcium arsenate problem which will put an ample supply of poison in every county in the South at exactly the moment the cotton crop needs it.

Demand does not and cannot change the industrial classification of a byproduct. This byproduct supply of arsenic being limited and increase or decrease in its production being controlled by factors having absolutely nothing to do with the demand, it is evident that it must be supplemented by direct production. And this means development of new processes and establishment of new plants with consequent investment of capital. All this cannot come in a day or a month or a year, even though the need be as great as it is at present.

So with the increasing of existing plants producing calcium arsenate from commercial byproduct arsenic and the building of new ones utilizing the same methods has come the establishment of new plants to produce commercial white arsenic direct from ore, new methods of producing calcium arsenate from white arsenic and of producing calcium arsenate direct from ore

Arsenic the raw material is largely a byproduct and has a historical record as to selling price more erratic than that of any recognized basic raw material for the chemical industries. The price chart on arsenic the world over for the last 20 years looks like a cross-section of the mountains of Switzerland. Even now with this tremendous demand springing up almost over night arsenic has not yet touched the high point of a few years ago Gentlemen, you might just as well accept the situation on a cold-blooded basis You cannot have a steady supply of any product of mine, factory or even of agriculture where the initiative of human agency is required unless the economic stimulus of steady demand is also existent It simply won't happen and a seasonal and fluctuating requirement for an indefinite quantity can't qualify as a steady demand Take the arsenic industry as it has existed in this country can you blame the smelters for regarding this small feature of their total production with indifference? They don't want to produce it they have to—it is in the ores they mine and smelt and they cannot help themselves. Formerly they let it go up their smelter stacks as not worth saving; but legislation compelled them to control these fumes, as the crude arsenic dust was naturally objected to by their neighbors So they began recovering it in the crude state and then refined it to make it marketable I venture to say that if this legislation of various Western states had not forced the control of arsenical smelter fumes in the past the arsenical insecticide industry would never have made the strides it has in recent years—entirely independent of and preceding the present boll weevil situation

I am going to close with an appeal for constructive co-operation between consumer and producer of boll weevil poisons I put the consumer first because his demand must come first and he must appreciate just that fact if he wants producers to function efficiently or at all

If this national boll weevil campaign can assist toward that, and I believe that it can, I am sure it will do one most constructive piece of work that needs doing very much indeed. After all that kind of thing is just what this campaign is for as I see it, to co-ordinate all agencies to the end that this pest be controlled and destroyed.

Engineering Foundation Elects Officers

The annual meeting of the Engineering Foundation's board of directors was held on Feb. 23, and immediately following the results of elections for officers was announced.

Charles F. Rand, treasurer of the A.I.M.E., was re-elected chairman. Edward Dean Adams of New York, Fellow of the American Society of Civil Engineers and member of the American Institute of Electrical Engineers, was elected first vice-chairman. Frank B. Jewett, president of the American Institute of Electrical Engineers, second vice-chairman; Joseph Struthers, treasurer, and Henry A. Lardner, assistant treasurer.

The new board of directors will be made up as follows: Alfred D. Flinn, Dr. W. F. M. Goss, Colonel A. S. Dwight, George H. Pegram, Bancroft Gherardi, S. H. Woodard, Prof. A. L. Walker, J. H. Barr, H. H. Porter, Dr. D. S. Jacobus, Prof. H. M. Boylston, E. W. Rice, Jr., E. A. Sperry and J. V. Davies.

Raw Material Survey Planned by Hoover

Production of Rubber, Sisal, Nitrates and Quinine Is Sought for U. S. Controlled Territory

RECOMMENDATIONS for an exhaustive investigation into the possibility of developing new sources of crude rubber in order that American consumers may avoid a shortage of supply and high prices as a result of the policy of restricted production and penalizing export taxation adopted by the British colonial governments were submitted to the House Appropriations Committee recently by Mr. Hoover and Assistant Secretary of Commerce Huston. Later the scope of this prospective investigation was broadened to include numerous other raw materials used by American manufacturers, the production of which is controlled by foreign countries.

For this reason the committee has been asked to make the appropriation of $500,000 required for a survey of crude rubber sources available for investigation into other import commodities where there is a growing tendency for restrictions and price control. Mr. Hoover believes that the government should ascertain possible sources of supply of crude materials in order to assure American industry free and unrestricted access to needed supplies. In addition to the rubber situation he intends to seek escape from foreign manipulation of the supply of nitrates, sisal for farm binder twine, quinine and other raw materials.

$100,000 for Experimental Work

Of the $500,000 suggested for the investigation it is planned that $100,000 would be available for experimental work on rubber. It is proposed that the rubber investigation should cover the economic problems of production in Latin America and the Philippines together, with probabilities of extended production in other quarters. Study would be made of such questions as comparative costs, available land, rubber supplies, laws, taxation and transportation facilities. Surveys of sources for other essential raw materials would be carried on along the lines of the program outlined for the rubber investigation.

In connection with this matter of rubber production it is of interest to note a memorandum recently handed to Secretary of War Weeks by the chief of the Bureau of Insular Affairs. This memorandum states that of all our insular possessions, the Philippines alone are suitable for development as a source of crude rubber. The Canal Zone is also available for this purpose—as the Republic of Panama already successfully produces the product.

Rubber in the Philippines

The memorandum continues:

"That rubber would grow in the Philippine Islands has been known and wild rubber has been collected and sold by the Moros and pagan people of Mindanao and the Sulu Archipelago for many years. Since the American occupation, most careful studies have been made of the possibilities of rubber production in the Philippine Islands. Reports bearing on this have been printed and circulated. Production has been experimental under the Philippine Department of Agriculture and it has been undertaken in a commercial way by private parties and there is at present produced on rubber plantations in the Philippine Islands about 202,000 lb. a year, which is increasing as new trees come into production.

"It may be stated that people in the United States seriously interested in the production of rubber are well advised of the possibilities of rubber production in the Philippine Islands. This matter has been laid before them in every possible way for a number of years. In the year 1917 Mr. Pearson, editor of the *India Rubber World*, made a trip to the Philippine Islands for the purpose of investigating the rubber situation there. His report, which ran through several numbers of the *India Rubber World*, was most favorable to the profitable production of rubber in the Philippines. There are available in the bureau estimates covering every feature of the planting and production of rubber in the Philippine Islands, some of which are taken from the actual plantation results."

The situation with the other raw materials mentioned above and with others not mentioned is not so urgent as that at present obtaining in the rubber market. The possibility, however, of such a situation developing in them is latent, and it is for this reason that the Department of Commerce wishes to make the broad general survey now planned. The department feels that there is a surprising number of different combinations which hold the American market at their mercy in point of prices and quantity of supply.

Status of Other Raw Materials

Sisal, for the manufacture of binder twine, for example, is produced almost entirely in the Province of Yucatan, Mexico, and the prices for this harvest necessity have been as thorns in the flesh of the Middle Western farmer for years. Quinine, originally produced in Peru, is now cultivated in the Far East and bought by this country through Great Britain or the Netherlands under very much the same conditions that the American rubber supply is obtained.

Raw nitrate production in Chile is almost wholly under British or Chilean capital, and it is the intention of the department to open up avenues for the entry of American capital into the business of furnishing the home maker with this and other necessary commodities unhampered by the commercial policies of other nations.

Activities of the C.W.S.

Secretary Weeks in Speech to Agricultural Editors Lauds Pest Destruction

Peace activities of the Chemical Warfare Service and what they mean to the farmer were pointed out by the Secretary of War on Feb. 26 during the course of an address before the American Agricultural Editors' Association. Among other things, Mr. Weeks said:

One cannot pass by the matter of pest destruction without consideration of the work of the Chemical Warfare Service. As you know, while we deprecate the use of gases in war, we have determined that we must be prepared to defend ourselves against any possible use of poison gases by unscrupulous outlaw countries. In studying this problem to assure the effectiveness of our gas masks and other defensive appliances we must investigate the effects of all poisonous compounds. It is the policy of the War Department to conduct our investigations so that the data which we discover can be given every possible peace-time use in addition to serving the defensive purpose. The Chemical Warfare Service has accordingly been able to make valuable contributions to the medical science, to the dye industry, and finally, to the work of pest extermination. The Public Health Service is already using with great effect the compounds recommended by the Chemical Warfare Service for the fumigation of ships and public warehouses. The Agricultural Department is becoming very much interested in their recommendations for the destruction of the boll weevil, the corn borer, the potato hopper and lesser pests. In the Philippines the chlorine compounds of the Chemical Warfare Service, and their flame throwers, are being experimented with for the destruction of the locusts which periodically invade sections of the islands, and appear to promise great success in eliminating this great scourge. I need not dilate on the importance of finding a way to eliminate the boll weevil and the corn borer, since you gentlemen know better than I that these pests are spreading with a rapidity that actually threatens human life in all countries. I understand that in one section of Ohio the extreme method of the embargo is being considered as a necessary safeguard for agricultural prosperity. The corn borer, like the potato hopper, lives, as you know, in the inner parts of the plant so that it is difficult to reach with sprays which must be eaten by the creature to cause its death. The various gases which are studied by the Chemical Warfare Service are likely to prove effective, however, for the reason that they penetrate so readily and need only contact with the skin of the insect to cause death. They are effective, moreover, against eggs as well as adults. I feel confident that the hearty co-operation of the Chemical Warfare Service with the Agriculture Department will in time produce results of gratifying value to the farmer.

Chemical Plants in the Occupied Territory

A second installment of the comprehensive list of important chemical manufacturers in the Ruhr Valley and adjacent districts in the occupied German territory has just been issued by the Commercial Intelligence Division of the Bureau of Foreign and Domestic Commerce, Washington, D. C. The names and addresses of additional plants at Düsseldorf, Duisburg, Essen, Gelsenkirchen, Höchst-on-the-Main, Kehl, Krefeld, Leverkusen, Linden, Ludwigshafen and Mainz are included on this list, which covers 500 establishments. The form of presentation is the same as that in the first installment which was given in detail on pages 341 and 342 of last week's *Chem & Met.*

Proposed Regulations to Prevent Dust in the Sugar Industry

National Fire Protection Committee Makes Report to Be Acted Upon at the Annual Meeting in May

THE sub-committee report on "Proposed Regulations for the Installation and Use of Grinding and Pulverizing Systems for Sugar" has been approved by the main committee on dust explosion hazards of the National Fire Protection Association. This code is to be recommended for tentative adoption at the annual meeting of the association in May. In the meantime, however, there will be a meeting of the committee at the Hotel Statler, Buffalo, March 5 and 6, to consider further suggestions.

Anyone interested in these regulations and desiring to suggest additions or changes should communicate at once with David J. Price, chairman, U. S. Bureau of Chemistry, Washington, D. C.; or Mr. Price may be addressed in care of the Hotel Statler, Buffalo, on March 5 and 6. The regulations proposed are as follows:

These regulations are issued to eliminate or reduce the hazards inherent in the manufacture of pulverized sugar, particularly the avoidance of its ignition and the propagation of a resulting fire. It is essential that there shall be no escape of dust into the atmosphere of the room, a condition favorable to a dust explosion.

For this reason it is important that the apparatus be provided with effective appliances to prevent and confine the ignition; proper venting of the apparatus and ventilation of the pulverizing department are important.

The term "pulverizing department," as used in these regulations, comprises the portion of the plant in which the pulverizing processes are carried on. The equipment may consist of the mills or pulverizers, scalpers, bolters, or screens, dust collectors and conveying apparatus.

Location. The processes of pulverizing sugar should preferably be carried on in a detached building used for no other purpose and located at a safe distance from other property, or if close by, have exposing walls blank and parapeted; such structure, except the exposing walls, to be of light incombustible materials.

If the processes, owing to the nature of the business, must be carried on in the main plant, the portion of the plant devoted to them shall be segregated and be located, if possible, in the upper stories under the roof.

Construction. When the processes are carried on within the main building or buildings of the plant, the walls, partitions, floors and ceilings of such section of the plant shall be not less than 4-in. reinforced concrete or the equivalent in strength and fire resistance.

A portion of the exterior walls and roof (considered in lieu of an exterior wall) equal to not less than 10 per cent of the combined area of the inclosing walls shall be of light incombustible material, preferably thin glass; provided that when in a building with other processes not more than 40 per cent of any exterior wall shall be of such material. Window ledges, girders, beams and other projections shall have the tops beveled or other provision be made to minimize the deposit of dust thereon.

Communications. Wherever possible access to the pulverizing department shall be from the outside; this can be accomplished by means of balconies. Where this is not practicable and direct communications are required, these should be protected by standard self-closing, hinged Class B fire doors, swinging outward from the rooms in which the processes are conducted, unless safe egress is provided to the outer air, in which case standard automatic sliding doors may be used to protect the openings.

Where power is transmitted to apparatus within the rooms from any driving mechanism or unit outside of same, the transmission medium—belt or chain—shall be incased both inside and outside of the pulverizing department in dust-tight inclosure, constructed of substantial non-combustible material. Where power is transmitted by means of shafts, the same shall pass through close-fitting shaft hole in wall or partition.

All pipe openings through walls or partition shall be tight.

No conveyors' spouts or chutes shall pass through any of the inner or separating walls of the portions of the plant containing the pulverizing department.

Spouts through the floors within the pulverizing department and from the lower floor to the packing or storage section must be of substantial metal construction, and tight.

Power. If electric motors are used these should preferably be located outside of the pulverizing department and the power transmitted as noted under communications. If inside of this department, they must be in accordance with the standards of the National Electrical Code for dusty locations.

All controlling and circuit breaking devices, if within the pulverizing department, must be of the inclosed approved safety type, cabinets or inclosure must be dust-tight and kept locked when apparatus is in operation. See Electrical Code.

Lighting. Electric incandescent lights only shall be permitted in the pulverizing department. Lamps shall be inclosed in dustproof globes provided with approved wire guards, in accordance with the National Electrical Code.

Switches and cut-outs shall be approved and dust-tight. These should preferably be located outside of the rooms containing the pulverizing department.

Wiring. All wiring shall be in conduits, in accordance with the National Electrical Code.

Preventive Measures.

a. All apparatus must be properly and securely installed to insure constant true alignment and avoid hot bearings or friction. It should be equipped with such devices as will prevent ignition or confine the results of ignition, and devices which will minimize the amount of dust in the atmosphere. The apparatus should be installed and arranged in unit systems so that pulverizers will deliver to but one set of scalpers and bolters; interconnections between sets of apparatus should not be permitted.

b. All mills or pulverizing apparatus together with their pulleys, shafting and belts shall be electrically grounded in an effective manner.

c. All sugar delivered to the mills or pulverizers shall be through ¼-in. wire mesh screens and over magnetic separators. If sugar is dumped into delivery hoppers from a floor above the mills, these hoppers should have a curbing at least 7 in. above the floors and be provided with screens of ¼-in. mesh.

d. Delivery spouts or receiving hoppers immediately above the mills which require openings for inspection of the sugar shall be provided with wire mesh screens of not more than four meshes to the inch.

e. The mills shall either discharge the pulverized product directly through spouts or scroll conveyors into the screens, bins or bulk containers, or the product shall be discharged from the mills by air currents set up by the centrifugal force of the blades or beaters and an inclosed fan, or the pulverized sugar shall be removed by means of an exhaust fan

f. Mills delivering directly through spouts should be provided with devices in or underneath the discharges which retard the flow of sugar in such a manner as to keep a small space immediately underneath or near the discharge filled up with pulverized sugar, thus smothering any spark that may originate in the mill This can be effected either by means of a revolving choke valve, or if sugar is delivered directly into the scroll, by the omission of a small portion of the blade and substituting therefor pins.

g. Blowers or exhaust fans shall be installed on proper foundations and secured in a substantial manner and shall not be used for any other purpose.

Where practicable the exhaust fan should be located beyond the collector. When located between the collector and the pulverizing apparatus or any portion of same from which the dust is to be removed, the blades should be of composition bronze, or the casing consist of or be lined with similar material. Ample clearance shall be provided between the blades and the casing. See Blower Rules of the National Board of Fire Underwriters

The fan bearings must not extend into the casings, and if possible be self-oiling.

h. Screens (scalpers, bolters, etc.) shall have their reels or sieves in dust-proof inclosures. When connected to dust collectors, the flues shall be of metal, and the collectors shall be properly vented to the outside of the building.

i. Dust collectors shall be vented to the outside of the building. Where cloth or stockinet tubular dust collectors are used, these must be in tight metal inclosures, with tight-fitting doors and be vented to the outside of the building. If practicable, dust collectors should be located outside of the building.

j. Vents must be of ample size. These are especially required at certain types of mills, screens, dust collectors and elevator heads. The vent flues must be substantially constructed of metal and be carried out of doors as directly as possible, avoiding especially short turns—never through an adjoining building or room—and be properly proportioned.

Vent outlets should be provided with cowls or hoods, and where the non-escape of dust is essential, with counter-balanced relief valves or covers provided with a soft felt gasket, at least ⅜ inch thick

k. Open flames of any kind, or any operations or repairs resulting in sparks or utilizing heat, should not be permitted in the pulverizing department while in operation or when the air is charged with floating particles of dust.

Housekeeping. Good housekeeping is one of the most important factors; apparatus which will not leak and permit the escape of dust or sifting out of the sugar is essential. Accumulations of escaping sugar or sugar dust must not be tolerated in the building. It is recommended that the interior of the pulverizing department be painted a color which is in contrast with that of the dust.

Fire Protection. The building or rooms in which the processes of pulverizing are carried on should be protected by a system of approved automatic sprinklers, and approved first-aid fire appliances, together with small hose.

A.I.C.E. to Meet at Wilmington

The American Institute of Chemical Engineers plans to hold the summer meeting at Wilmington, Del., June 20 to 23. A program of papers is being prepared on the general topic of Adsorption Agents, including Activated Carbons, Bone Char, Silica Gel, etc. Members are asked to contribute papers along this line. In accordance with a rule adopted at the Richmond meeting copy of papers to be delivered must be sent to the Secretary 60 days before the meeting—i.e., not later than April 21, 1923.

U.S. Chamber of Commerce Aids Distribution

The Elimination of Excess Varieties Urged as a Help Toward Efficiency

The domestic distribution department of the Chamber of Commerce of the United States has launched a movement among the distributors of the country looking to the elimination of excess varieties in all lines of merchandise. In this connection, the department has just issued an illustrated pamphlet in which great stress is placed upon the savings and increased profits which can be effected by an active study of simplification.

It is stated in the pamphlet that "today, through useless competition, variety has been piled upon variety, visiting upon distribution much expense and confusion of effort."

To substantiate this contention, the pamphlet cites the following appropriate example: "In a certain industry there had been futile attempts for several years to reduce the number of forms such as order blanks, receipts, shipping manifests, etc., to some sort of uniformity and consistency of practice. Hundreds of varieties were in use but not more than six or eight were needed. The problem was precisely the same in every establishment so far as their relations with customers were concerned. Yet although there was a strong demand within the association for a reduction in the number of these forms, some trifling but unconquerable reasons existed to explain their inability to proceed. Upon appealing to this department, a method was devised which involved a conference between the representatives of this department, of the industry and of the Department of Commerce, as a consequence of which a committee was appointed which after a few months' study has reduced the several hundred forms to a maximum of eight and which presently will offer its report for adoption by the associated industry as a whole."

Too Many Styles in Dress

In dealing with styles, the department points out that "even the most casual investigation of this subject leads into the ungoverned whirl of a vicious circle. At least a beginning might be made in those trades where fashion is an important element, by a study of certain general types. It might be discovered that shoes will lend themselves to some reduction; and even women's hats might yield certain results if a study were made of the frames upon which are fastened the fluffs of fur, flowers, feathers, fruits and farm products. Men's clothing presents many difficulties, but reasonable modifications in the violent fluctuations in the height of the waist line, in the size of the trousers, in the inclination of the pockets or in the number of buttons on a sack coat may be found practicable. Indeed, a study is being made now of the many varieties of blue serge in order to abandon those which serve no purpose of style or of utility. Briefly, in order to accomplish a multitude of reductions in the number of varieties it is necessary merely to arouse a sympathetic state of mind among manufacturers and distributors."

"A period has arrived in distribution," the pamphlet concludes, "when the demand is insistent that distributors shall manifest an active interest in the betterment and progress of that branch of business through which they serve the public, and our duty as the domestic distribution department of the Chamber of Commerce of the United States places us squarely before you as an agency to co-operate with you to the extreme limit of our capacity."

Number of High-Analysis Fertilizers Reduced

Conference of Agronomists Agrees to Reduction From 200 to 32 in Eighteen States of Middle West

As the result of the third group conference for the purpose, held at Baltimore recently by agronomists representing the Middle Atlantic States, agreements are in existence for the recommended use of high-anlaysis commercial fertilizers in eighteen states of the Middle West, the North and the East whereby the number of grades which are to be pushed for sale among the farmers have been reduced from more than 200 to 32.

Officials of the Soil Improvement Committee of the National Fertilizer Association, which was represented at each of these conferences, characterize the program now undertaken as far in advance of any previous plan and believe that the groundwork has been laid for great improvement and economy in fertilizer practice. Just what it will mean in lower plant-food costs to the farmers depends upon the farmers themselves, for while the agricultural colleges and the fertilizer salesmen will recommend and push the particular high analyses selected for each group of states, other grades will be delivered if the purchasers demand them.

A high-analysis fertilizer has been defined as one which contains 14 per cent or more of plant food elements, this line of demarkation having been recommended by the Soil Improvement Committee in 1918 and agreed to as feasible and satisfactory by the agronomists and manufacturers.

Specific Reductions Made

Participating in the Baltimore conference, held Feb. 8 and 9, were agronomists representing New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia and West Virginia and thirty of the manufacturers marketing fertilizer in these states. Nineteen analyses were agreed upon, fifteen for general purposes and four for special needs in limited areas. In Maryland alone last year, 192 different analyses were registered, twenty-six of them representing 81 per cent of the total tonnage and the remainder being divided in small lots among 166 analyses. High-analysis fertilizers agreed upon for the Middle Atlantic States are: For general use, 0-12-6, 2-12-2, 2-10-6, 2-12-4, 3-8-3, 3-8-8, 3-10-6, 4-8-4, 4-8-6, 4-12-0, 4-12-4, 5-8-5, 5-10-5, 6-8-4, 7-6-5; for special use, 0-10-10, 0-10-4, 4-8-10, 10-5-0.

At a conference in October, fifteen high analyses were agreed upon for Ohio, Indiana, Michigan, Wisconsin and Missouri, being: For mineral soils, 0-12-6, 0-14-4, 2-12-2, 2-12-4, 2-12-6, 2-16-2, 3-12-4, 3-8-6, 4-8-6, 4-12-0, 2-14-2; for organic soils, 0-8-24, 0-10-10, 0-12-12, 2-8-16.

New England agronomists and manufacturers at a conference in Boston in January agreed upon nine high analyses for use in Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut. These are: 0-12-6, 2-12-4, 3-10-4, 3-10-6, 4-8-4, 4-8-6, 5-4-5, 5-8-7, 8-6-6.

Equipment Men to Exhibit at New Haven

Due to the frequent requests of several firms, the executive committee of the New Haven-Connecticut Valley Sections in charge of the coming meeting of the American Chemical Society at New Haven has decided to make available space for exhibits of an educational and professional nature. These will consist largely of laboratory apparatus and new equipment of interest to chemists. The building used for this purpose will be the old Sheffield Chemical Laboratory, which is now vacant. Apparatus dealers and publishers of scientific books may arrange for space by addressing Prof. T. B. Johnson, Room 157, Sterling Chemical Laboratory, New Haven, Conn. There will be a nominal fee charged to cover the use of the building and service.

American Institute of Chemistry Council Meets

The Council of the American Institute of Chemistry at its meeting on Feb. 19 appointed a committee consisting of Dr. Frederick Crane, Miss C. M. Hoke and Lloyd Lamborn to prepare a four-page folder setting forth the purposes and plans of the Institute, and to provide for its presentation to the chemists of the United States. It also directed incorporation under the non-profit-sharing corporation law of the State of New York.

Plans are being arranged for the formation of skeletonized committees to deal with questions of ethics, professional classification and certification, and employment conditions. These problems are fundamental ones to the organization and after study and co-operative consideration an attempt will be made to solve them. The Council invites correspondence on these topics as well as on the general plans of the Institute.

Papers and Speeches for Spring A.C.S. Meeting

More Detailed Information on Topics of Meeting Now Made Available by the Society

Progress in all branches of industrial and theoretical chemistry will be reviewed in detail at the sixty-fifth general meeting of the American Chemical Society at New Haven, Conn., April 2 to 7.

One of the most important features of the week will be a symposium on "Motor Fuels," held jointly by the Division of Petroleum Chemistry and the Section of Gas and Fuel Chemistry. The results of various investigations as to the worth and quantity obtainable of alcohol blends, new methods of producing gasoline from petroleum and natural gas, work in blends of benzol and kerosene, and other blends will be reported. Papers will be presented also covering the most recent discoveries in regard to anti-knock compounds, more efficient carburetion and other subjects which have a direct bearing on the problem of keeping the supply of motor fuels of all kinds equal to the demand.

History of Coal-Tar Dyes

Another important discussion will be that of the Division of Dye Chemistry, which has arranged for a symposium on "The Coal-Tar Dye Industry in the United States Prior to 1914."

The most recent facts and theories concerning nutrition will be brought out in the meeting of the Division of Biological Chemistry, which will hold a symposium on that subject. Noted authorities on matters of nutrition will present papers, and recent work in the attempt to isolate and get a better understanding of vitamines will be reviewed.

Because of the wide concern over the cotton boll weevil and other destroyers of crops, agricultural chemists have been busy with experimentation and research related to these problems in the last few months. Their progress will be reported in a symposium on "Insecticides and Fungicides," at the meeting of the Division of Agricultural and Food Chemistry.

Chemical problems involved in the production of artificial silk, paper, guncotton, smokeless powder, celluloid and pyroxylin lacquers will be discussed in various papers to be presented before the Division of Cellulose Chemistry. This division will deal particularly with recent achievements in the artificial silk industry at a symposium on "Oxycellulose, Cellulose Hydrate and Hydrocellulose.'"

The Division of Rubber Chemistry will honor the memory of Charles Goodyear, who, by his pioneer work on the vulcanization of rubber, made possible the rubber industry today.

Weeks and Garvan to Speak

Among the men of prominence who have accepted invitations to speak at the general sessions of the society are Secretary of War John W. Weeks and Francis P. Garvan, president of the Chemical Foundation.

The dedication of the Sterling Chemistry Laboratory of Yale University will be held on Wednesday, April 4, at which members of the chemical society will be guests of Yale.

Chemists of international note who will be present and take part in the dedication exercises and also in the chemical society meetings will be Prof. W. Lash Miller, of Canada; Prof. G. Urbain, of France; Prof. F. G. Donnan and Principal J. C. Irvine, of England; Prof. G. Bruni, of Italy; Prof. A. F. Holloman, of the Netherlands; Prof. The Svedberg of Scandinavia, and Professors M. Gomberg, G. N. Lewis and A. A. Noyes, among others, will represent the United States.

It is expected that 3,000 chemists will attend the general meeting.

French-Badische Convention Is Ratified

France to Produce Ammonium Sulphate and Ammonia Nitrates Under German Supervision

The bill to ratify the convention between the French Government and the Badische Anilin und Soda Fabrik was ratified by the French Chamber of Deputies on Feb. 8 by 555 votes to 5. France needs 110,000 tons of nitrogen annually for agricultural manures. In addition, in war time France would need about 100,000 tons of nitrogen for explosives. At present France produces about 19,000 tons and imports about 34,000 tons annually. Germany produces over half a million tons, and under Art. 297 of the Versailles treaty is entitled to retain this amount. France obtained possession of the formula of the Haber process during the war, but all the efforts of the French chemists to utilize the formula for the manufacture of nitrogenous products failed. It was in order to obtain the secret of the practical manipulation of the formula that the French Government signed on Nov. 11, 1919, the convention with the Badische Anilin und Soda Fabrik.

The main lines of the convention are as follows: The Badische Fabrik shall supply to France full details of the method of manufacture of the above-mentioned nitrogenous products as employed in the company's factories at Oppau and Merseburg. The Badische Fabrik is to supply complete plans for the construction of a factory in France capable of producing 100 tons of nitrogen daily and to send experts to superintend the construction and working of the factory. Until the factory attains a certain stipulated productivity the Badische Fabrik is to give free access to French official experts to study the methods at the Badische company's factories. Lastly, the Badische Fabrik renounces for the period of the convention all right of manufacture and sale of these products in France, the French colonies and protectorates. In return France pays the Badische Anilin und Soda Fabrik five million francs as "architect's fee" payable in two installments, of which the first was paid on April 4, 1920, and the second will be payable when the French factory produces a minimum of 20 tons of nitrogen per day consecutively in a fortnight.

France also pays the Badische company a sliding scale percentage on the factory's production of nitrogen estimated according to the average c.i.f. price of Chilean nitrates at French ports, with a minimum of half a million francs yearly. It is estimated that the percentage will be equivalent to 2 per cent of the sales.

The convention is to continue for a period of 15 years from the date when the factory produces 30 kg. of nitrogen daily. On the expiration of the convention, France retains all the rights of patents and good will acquired thereunder. The bill proposes that a limited liability company should be formed with a capital of 50,000,000 francs, of which three-fifths of the shares are to be subscribed by the state and the remainder in fixed proportions by the agricultural associations, chambers of commerce, workers' co-operatives and the general public. This company would lease from the state a portion of the Toulouse powder factory, which is to be converted into a nitrates factory.

The bill aroused considerable opposition, especially from the interests behind the factories employing the process invented by the Frenchman Claude. The critics assert that the bill unfairly favors German against French invention, to which the advocates of the bill reply that there is room for both.

Dinners at New Haven A.C.S. Meeting

Thursday, April 5, 6:30 to 8:30 p.m., will be reserved for fraternity and college reunion dinners, and it is expected that this will be found to be one of the most enjoyable features socially of the New Haven meeting of the American Chemical Society. The University Dining Hall, which has a seating capacity of over 1,500, is available for this service. Arrangements for these college reunion dinners and reservations should be made as early as possible by communication with Dr. Arthur H. Smith, 94 Woodlawn St., Hamden, Conn.

New Jersey Chemists Meet

The New Jersey Chemical Society met at Stetters in Newark, N. J., on the evening of Feb. 12. After dinner and a short social meeting, a technical program was given. Dr. Colin G. Fink, of the division of electrochemistry, Columbia University, spoke on "Modern Methods in Metallurgical Research," confining most of his attention to problems of corrosion of non-ferrous alloys. Following Dr. Fink, Charles P. Titus, president of the New York Microscopical Society, spoke on the "Microscopical Investigation of Cigarettes." The meeting was attended and enjoyed by a large gathering of New Jersey chemists and metallurgists.

Safety Code for Walkways Urged

A conference attended by sixty-three representatives of trade associations, technical societies, safety organizations and government departments, held in the Engineering Societies Building in New York, Feb. 14, declared by unanimous vote "that it is desirable to have a nationally uniform safety code on walkway surfaces" and that the development of this code should be carried out under the procedure of the American Engineering Standards Committee.

The conference voted to include in the code the following places: elevator floors, elevator landings, corridor floors, ramps, runway floors, stair treads and landings, fire escape treads and landings, floors around machinery and at door thresholds, and sidewalk hazards such as coal hole covers and sidewalk doors. This new code will apply to apartment houses, factories and other working places, office buildings, hospitals, hotels and restaurants, railway cars, railway stations and train platforms, schools and theaters.

The conference voted that the performance characteristics which should be considered in walkway surfaces are: resistance to slipping, durability, freedom from the tripping hazard, and flammability. General and maintenance requirements will also be included in the code.

Following the conference, the manufacturers' representatives met and appointed a committee, under the chairmanship of H. W. Mowery, to arrange for representation, in the continuing work, of manufacturers of the various classes of floors and floor coverings, in view of the fact that several of these classes of materials are not covered in any trade association.

The next step in the development of this code will be the appointment of sponsors by the American Engineering Standards Committee and the organization of a sectional committee which will draft the code. This sectional committee will be composed of official representatives of all organizations concerned with the subject of safe walk way surfaces, either as producers, consumers, casualty underwriters or governmental officials representing the general public.

Auto Manufacturers Enter Glass Business

Two items in the past week's dispatches illustrate the increasing tendency on the part of great manufacturers to control the sources of supply of the different elements entering into their products.

According to the first item, Henry Ford definitely enters the industrial field in the Pittsburgh district with the acquisition of the Allegheny Plate Glass Co. at Glassmere. The Ford interests take possession of the plant immediately and will use it to produce plate glass exclusively for automobiles.

The Allegheny plant, which covers 40 acres of ground, is one of the largest and most completely equipped in the world. Its annual output is between 6,000,000 and 7,000,000 sq.ft. of plate glass.

The second item reports that W. C. Durant has acquired control of the American Plate Glass Co., located at Kane, Pa., by purchasing the entire stock of the company. The plant has a capacity of between 5,000,000 and 6,000,000, sq.ft. of plate glass a year, which is sufficient to meet all requirements of the Durant enterprises for some time to come. Mr. Durant stated that the purchase was made in order to avoid any possibility of being handicapped through a shortage of plate glass.

The American Plate Glass purchase will be independently financed, it was announced, and 249,000 partners in Durant enterprises will be given an opportunity to invest in it and to participate in the profits to be derived from existing and future business.

Personal

Dr. THOMAS F. BAKER, who has been acting president of the Carnegie Institute of Technology, Pittsburgh, since the resignation of Dr. Arthur A. Hamerschlag last July, has been elected president.

R. C. BURTON, of Zanesville, Ohio, has been elected president of the National Brick Manufacturers' Association.

Dr. H. C. COOPER has removed from New York to Chicago, to become director of the scientific department of Bauer & Black, manufacturers of surgical dressings, etc. Dr. Cooper was for a number of years professor of chemistry in Syracuse University. In 1918-1920 he had charge of physical chemistry and electrochemistry at the College of the City of New York, since which time he has been manager of the electrochemical plant of the Acids Manufacturing Corporation. He was recently chosen chairman of the New York Section of the American Electrochemical Society.

D. P. GAILLARD, who was commanding officer of the Old Hickory Ordnance Reserve Depot, Jacksonville, Tenn., is now assistant to the director of the Fixed Nitrogen Research Laboratory of the Department of Agriculture, Washington, D. C.

W. A. GRAY, JR., who was superintendent of the Romage process, Bransdall Refining Co., is now a member of the staff of the general engineering department of the Standard Oil Co. (N. J.), at Elizabeth, N. J.

J. H. HALL, assistant professor of chemistry, Illinois State Normal University, Normal, Ill., has resigned to accept a position as research chemist with the California Fruit Exchange. He will begin his new duties about March 8, and will be located in the Exchange laboratory near Los Angeles.

CARLTON C. JEWETT, of Buffalo, N. Y., has been appointed treasurer of the Dunlop Tire & Rubber Co., with the local plant.

P. M. MCHUGH, of the Dorr Co., who recently returned from an extended trip to Hawaii, sailed for Cuba on Feb. 21. He will return in 3 or 4 weeks.

RANDOLPH MILLER, formerly assistant secretary of the Kokomo Rubber Co., Kokomo, Ind., has been elected treasurer and director, succeeding D. L. Spraker, resigned.

Dr. HOBART ROGERS of the School of Medicine, Indiana University, gave an interesting address before the members of the Butler College Chemical Society, Indianapolis, Ind., Feb. 16, on the subject of "Physiological Chemistry."

LLOYD L. ROOT, of Grass Valley, Calif., for several years superintendent of the Mexican Candelaria Mines Co., has been appointed state mineralogist to succeed Fletcher Hamilton.

Dr. WALTER RUNGE, consulting engineer, of New York City, sailed for England on Feb. 17 on professional business. He will return some time in April.

ACHESON SMITH, past president of the American Electrochemical Society, is in Europe and expects to return early in March.

FRANCIS M. TURNER, JR., is giving a course of six lectures on Chemical Plant Equipment at the University of Toronto, Feb. 26 to March 3.

Obituary

CYRUS BORGNER, founder and president of the Borgner Fire Brick Manufacturing Co., Philadelphia, Pa., and prominent in civic affairs, died Feb. 13, at his residence, 6041 Drexel Road, Overbrook, aged 73 years. He was for a number of years treasurer and president of the Franklin Institute of Philadelphia, and at the time of his death was vice-president of the local Manufacturers' Club. He was a director of the Philadelphia Bourse and vice-president of the Philadelphia Chamber of Commerce. He is survived by his wife, one son and two daughters.

WILLIAM PENN WORTH of Coatesville, Pa., pioneer iron and steel manufacturer, president of the Worth Steel Co., Claymont, Del., died at his apartments, St. James Hotel, Philadelphia, Feb. 14, of heart disease, aged 67 years. At the time of his death he was president of the Coatesville National Bank. He is survived by his wife, three sons and two daughters.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

How the Business Cycle Works

Basic Causes of Periodic Ebb and Flow of Commercial Activity Are Clearly Explained in Analysis of Retailer-Wholesaler Relations

IN A FORUM meeting of the New York Credit Men's Association on Feb. 20, Prof. Willford I. King, of the National Bureau of Economic Research, presented an unusually clear explanation of how the business cycle operates. By developing his subject in such a way as to show how different commercial developments affect the retailer and wholesaler, he was able to give concrete expression to the basic economic conditions on which the cyclic theory rests. His address goes a long way toward answering the objections commonly held that "the idea of a business cycle is too indefinite to be of any practical value" and that "business conditions are constantly affected by an infinite variety of unpredictable forces of various strengths."

Extracts from Professor King's address will be found in the following paragraphs:

Economists have noted the apparent existence of three important cycles, with wave lengths of about 20, 7 and 3½ years. Apparently, the last mentioned is the most clearly defined, its waves being higher than those in either of the others. However, it is unusual for severe depressions to occur oftener than once in 7 years, and the fact has been often noted that for a long period—namely, in 1837, 1857, 1877 and 1897, deep depressions occurred at 20-year intervals.

During these depressions the retailers cannot indefinitely continue to reduce their stocks. Their shelves become so nearly empty that buying cannot longer be avoided. As their purchases rise to equal the current requirements of their customers, the resulting demands on the wholesalers cause a rise in wholesale prices. As wholesale prices climb, retailers realize that prices have been low, and begin to purchase more heavily. This makes wholesale prices rise more sharply. The retailers become more and more alarmed at the rise in wholesale prices and buy faster than ever. Stocks accumulate at a constantly accelerated speed. The rise in wholesale prices goes on with added momentum.

Manufacturer Feels Demand

Wholesalers pass the demand along to the manufacturers An increasing demand at rising prices sets idle factories in motion. As demand increases, increasing factory production is followed by higher prices for factory products. Manufacturers' profits increase. As factory owners see sales and prices both rising and profits growing, they infer that sales and prices will keep on rising and profits will keep on growing. They therefore hasten to hire more labor, to contract for more raw material before prices go up, and to borrow more money to finance their enlarged operations. They thus expand their business because they believe that in the near future they will be able to market a still larger supply of their product at prices higher than ever. The increase in their activities naturally causes an increase in the price of the raw materials they are purchasing, and a rise in the price of labor.

As the cycle moves upward the retailer must buy upon a rapidly rising market, but the physical volume of his sales gradually tends to diminish, while his stock constantly increases. At first this situation causes no alarm, but for some reason or other he finally wakes up to the fact that he has on hand a very large inventory, bought at extremely high prices, and that his sales are not at all satisfactory. This discovery marks the climax of the boom. Soon the retailer becomes panicky. He stops buying; on the way up he has been ordering more goods than he needs because he has expected to get only partial delivery on his orders. Now he finds that he is threatened with a flood of high priced goods which he cannot sell. He, therefore, not only stops buying, but tries to cancel the orders which he has already placed with the wholesaler. The wholesaler does likewise with the manufacturer. Suddenly the manufacturer finds that instead of being unable to produce goods fast enough to meet the demands of his customers, he is getting few orders, and cannot make deliveries on the old ones.

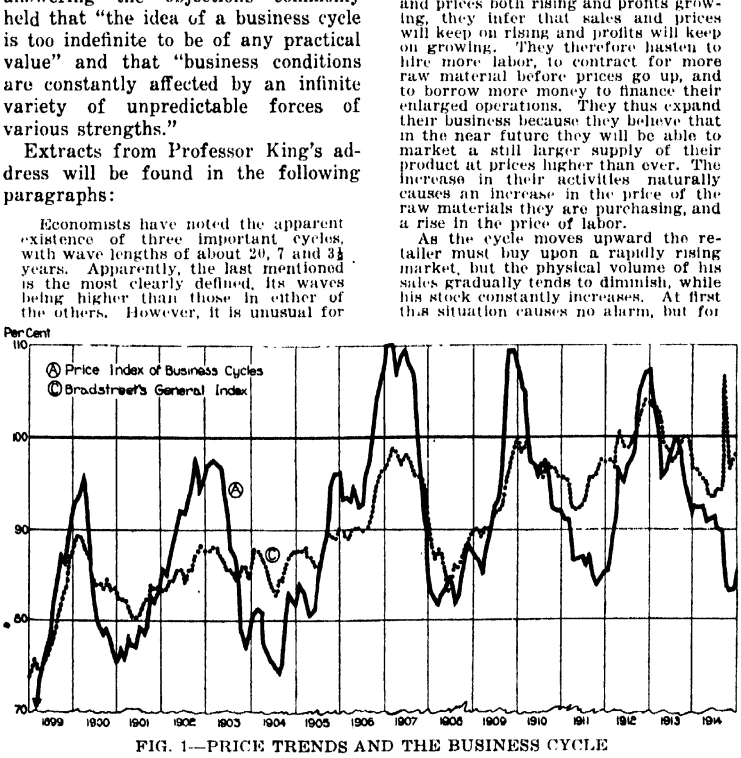

FIG. 1—PRICE TRENDS AND THE BUSINESS CYCLE
The Harvard Economic Service's price index of business cycles is compared with Bradstreet's price index.

"Chem. & Met." Weighted Index of Chemical Prices

Base 100 for 1913-14

This week	176.38
Last week	175.31
February, 1922	148.00
February, 1921	166 00
February, 1920	252.00
April, 1918 (high)	286.00
April, 1921 (low)	140.00

The continued strength in the cottonseed oil market, together with the manufacturer's advance in the price of copper sulphate, is responsible for the gain shown in this week's index number

The Lag Between Wholesale and Retail Prices

With the stoppage of purchases by the retailer, optimism suddenly turns to pessimism Wholesale prices being based upon anticipations, break violently. Retailers, however, follow the practice of selling goods at a certain margin above costs, therefore, although they have stopped buying, they at first cut prices but slightly. Some of them, however, are forced to reduce prices in order to collect money to satisfy their creditors, and these may make rather sharp price reductions. In general, however, retail prices fall rather slowly. A paradoxical situation thus arises. Although the first break in the boom occurred when the retailers stopped buying, nevertheless, retail prices remain rather stable, while the first really sharp price decline occurs at the factory, retail prices "tagging along" after factory prices at a distinctly later date. Apparently, though of course not really, the effect has preceded the cause.

When the manufacturers find new orders distinctly cut down and many of the old orders canceled, their natural tendency is to reduce output accordingly. They discharge employees and otherwise reduce expenses. This does not help them much, for they have borrowed money they expected to repay from the proceeds of larger sales at higher prices. With lower prices and reduced sales, some are unable to meet their loans. If creditors decide to "carry" them, the credits become "frozen." If creditors demand immediate settlement, the manufacturer in many cases will be forced into bankruptcy.

Eventually a stage is reached in which the retailers again find their large stocks running out and they are compelled once more to buy to meet the demands. Buying by retailers stimulates the wholesale business, which, in turn, places orders with the manufacturers. This starts the wave of optimism all along the line. Once again pr'ces begin to rise. The cycle is complete and business is again ready to start out of the trough up over a new wave.

The cyclic character in the trend of wholesale and retail prices is shown in Fig. 1, in which the price index of business cycles of the Harvard Economic Service is contrasted with Bradstreet's index over a rather extended period.

Copper Sulphate Advance Features New York Market

Imported Caustic Potash, Permanganate of Potash and Bleaching Powder Also Somewhat Higher—Market Generally Steady

NEW YORK, Feb. 26, 1923.

BUSINESS in the chemical market during the past week was somewhat quiet, but the general tone was of a comparatively steady character. Buyers have shown a disposition to operate on a conservative basis, due to the unsettled situation abroad and the uncertainty of spring business. The single feature of the week's activities, as far as prices are concerned, was the advance by domestic makers of copper sulphate. The continuous rise in the price of copper metal, together with the added buying interest among consumers, was the direct cause of the new advance. Imported goods have been advanced by leading dealers. Resale formaldehyde was quoted at much lower levels among several weak holders. Producers, however, continue to quote the market firm at former levels. The export situation in the alkali market showed considerable improvement, with several large tonnage inquiries noted from European centers. Barium chloride, prussiate of potash and oxalic acid were rather unsteady at slightly lower quotations. Caustic potash, permanganate of potash and bleaching powder showed continued activity and prices were notably higher during the latter part of the week.

High Spots of the Market

Arsenic—Resale material was fractionally lower at 15½@15¾c. per lb. Although business is somewhat dull, spot goods remain quite scarce and the general tone of the market is firm. Shipments were quoted at 15¼c. per lb.

Barium Chloride—Spot material was quoted down to $87 per ton by leading importers. Shipments from abroad were noted at $85 per ton. The general condition presents a rather unsteady situation.

Bleaching Powder—Large producers report a well-sold market at the works and quote $2.20 per 100 lb. for any prompt shipments. The resale market is very strong, with quotations heard around $2.50 per 100 lb., for large drums.

Caustic Potash—Imported material was much firmer during the interval and the lowest figure heard was around 7⅝c. per lb. The general range was 7⅝@7¾c. per lb. for 88-92 per cent. Cabled demand from abroad was responsible for the new advance.

Caustic Soda—The export market presented a stronger tone and several inquiries were received from leading European countries. Prices held around $3.45@$3.50 per 100 lb. f.a.s. Domestic inquiry continued very strong at $3.75@$4 per 100 lb., ex-store. Contracts remained quotably unchanged at the works.

Chlorate of Potash—Imported goods were quoted somewhat lower at 7c. per lb. for powdered and crystal. Several large tonnages were reported on dock from Germany during the past week. Producers were firm at 8½@9c. per lb.

Copper Sulphate—Producers advanced quotations to $6.50 per 100 lb. for 99 per cent large crystals and $6.40 for smaller crystals. The rise in the metal market and the strong consuming demand were responsible for the new level. Imported material was also advanced to $5.75 per 100 lb. on spot.

Epsom Salt—Domestic U.S.P. material was quoted at $2.50 per 100 lb., with technical at $1.75@$2 per 100 lb. Imported U.S.P. held around $2 per 100 lb. and technical at $1.10@$1.20. Demand was merely of a routine nature.

Formaldehyde—The market presented an unsteady tone with several second hands quoting as low as 15c. per lb. on spot. Producers were firm at 16c. per lb. in carload lots and 16½c. for lesser quantities.

Oxalic Acid—Producers quote the market at 12½c. per lb. f.o.b. works. Imported goods on spot held around 12¾@13c. per lb. Shipments were quoted at 12½c. per lb. duty paid. The demand was rather quiet.

Prussiate of Potash—The market appeared slightly lower, due to the lack of consuming interest. The yellow salt was quoted at 37½c. per lb., with a probable concession on actual business. Red prussiate was down to 80c. per lb.

Active Buying of Vegetable Oils

Linseed Oil—Leading crushers announced another sharp advance in prices to become effective Feb. 26. Late figures for nearby shipments ranged around 98c. per gal., carload basis in barrels. April shipment was quoted at 97c. per gal., with May at 94@95c. per gal. Foreign oil held quite firm, with March-April shipment from England at 94c. per gal., duty paid.

Castor Oil—Several odd lots of No. 3 grade sold as low as 12½c. per lb., but producers reported a strong market at 12¾c. The general inquiry showed material improvement, due to the stronger market for castor beans. The U.S.P. material was quoted firm at 13¼c. per lb., in barrels.

Coconut Oil—Prices were quoted along steady lines, although actual business was very quiet. Spot Ceylon type oil closed at 8½c. per lb., sellers' tanks. Cochin oil was quoted at 9¾c. per lb., prompt shipment, in barrels.

Corn Oil—The market appeared quite strong with a few odd lots quoted at 10⅛c. per lb., f.o.b. point of production. The general range was around 10⅛@10¼c. per lb. Spot in barrels was quoted around 11¼c. per lb.

Good Alkali Business in the St. Louis Market

Satisfactory Volume Reported Although Prices Are Somewhat Unsteady—Imported Chemicals Affected

ST. LOUIS, MO., Feb. 22, 1923.

Trading in industrial chemicals in this market has been very encouraging and there is a pronounced tendency toward higher levels. This is particularly true of the imported chemicals, which are affected by the European situation, and some rather heavy buying is being done in this line. The shortage of box-cars, interruptions and delays in transportation have caused serious shortages of stocks in many directions, and have also resulted in a firmer tone in the market.

Alkali Market Is Good

The market on alkalis is good. Prices are somewhat unsteady, but quite a volume of business is being transacted and usually at a fair price. Occasionally there are inside quotations, but as a rule quotations are as per schedule. *Caustic soda*, solid, is being quoted at $3.75 in 5-drum lots and $3.90 in single drums. *Flake* caustic in 5-drum lots can be had at $4.25 and $4.40 in single drums. *Soda ash* in ton lots in bags is being quoted at $1.95 per 100 lb. and in less than ton lots at $2.10 per 100 lb. The usual differential of 15c. for barrels over bags still holds. *Bicarbonate of soda* is moving in good volume and prices are quite firm. Barrels are generally being quoted at $2.40 and kegs at $2.60 per 100 lb. *Sal soda* is firmer than usual and quality material is quoted at $2 per 100 lb. in barrels, $2.25 per 100 lb. in kegs. Some low-grade materials are being offered at lower prices, but are not affecting the market generally.

Other Price Changes

Heavy *mineral acids* are in much better demand and the increased volume is very marked. *Citric acid* is not doing much, but developments are in order for the next few weeks. *Oxalic acid* is not moving so well and prices remain the same. Producers of *phosphoric acid* advanced their prices last week, but trading has not been so good. The season for this article is approaching, however, and a material increase should be expected. The movement of *tartaric acid* is fair, but should show more life very soon. The *white arsenic* situation is still very tight and supplies are very difficult to obtain. *Glycerine* is again very firm and without exception is being quoted at 18½c. in drums. Contract business is being done on the same basis and future predictions are for firmness. There has been no change in the price of *copperas* and supplies are easier, but little surplus has been accumulated. The demand for *cream of tartar* is increasing, but no large quantities are involved. *Potassium cyanide, granular*, is moving briskly. The market for *permanganate of potash* is extremely strong with a

heavy demand, but supplies are limited. *Sulphur* is holding its own in price and is increasing in volume. Quite a volume has been unloaded in this market recently. Refined flowers in 10-bbl. lots are quoted at \$3.85 per 100 lb., single barrels at \$4, light flour refined, in 10-bbl. lots at \$3.30, single barrels at \$3.40 per 100 lb. Roll brimstone is at \$3 per 100 lb., and crude sulphur in bags at \$1.90 in ton lots, \$2 per 100 lb. in less. *Zinc dust* has advanced ½c. since our last report and is now quoted at 10½c. in carload lots f.o.b. St. Louis, with a good volume of business transacted at this figure. The *zinc sulphate* market is very lively, and in one direction it is reported that the demand has been unusually heavy during the last 2 weeks. The market is firm with no change in price—3¼c. in carload lots f.o.b. St. Louis. *Zinc spelter* is very active and in good demand for domestic consumption as well as for export. Since the first of the year the market has advanced about \$15 per ton and today is quoted at \$7.40@\$7.50 per 100 lb., f.o.b. St. Louis.

Vegetable Oils in Better Demand

Linseed oil has firmed up quite lively and the market is now completely in the hands of the producers. Five-bbl. lots are quoted at \$1 for the raw and \$1.02 for the boiled oil, while 1- to 4-bbl. lots are quoted at \$1.11 and \$1.13 respectively per gallon. *Castor oil* is very firm at 14½c. per lb. in drums, and the present condition of the seed market would seem to indicate a still higher market. *Turpentine* is holding very well and is quoted today at \$1.54 per gal. in 5-bbl. lots and \$1.59 per gal. in single barrels.

Steel Market Shows Signs of Excitement

The Cause, However, May Be Found in the Widespread Tendency to Speculate

PITTSBURGH, Feb. 23, 1923.

The finished steel market presents a still more excited condition. Many jobbers and manufacturing consumers are seeking to place additional orders or contracts, and seem rather indifferent as to prices that may be charged. This is a familiar phenomenon in steel market movements and mills interpret it as indicating that there is a widespread tendency to speculate, by overrating prospective requirements and by endeavoring to anticipate price advances. Accordingly, a great deal of the offered business is being refused, or is being filed for entry later at prices that may then be ruling. The actual turnover in the market, in sales and purchases, is lighter than in January, and is made up largely of orders against actual construction projects.

The superficial appearance of the steel market, with a large volume of inquiry, with mills refusing to entertain much of the inquiry and with prices advancing, would suggest that steel is scarce and that there is not going to be enough to meet all requirements in the next few months. If such a condition develops, it will be unprecedented and not far removed from a miracle. For 5 months shipments of steel from mills have been very heavy, and they are at a greater rate still at the present time, with very favorable prospects for mill operation in March. On account of the time of year, consumption of steel in many quarters has been restricted.

In industrial activity there is always a limiting factor. Sometimes it is the amount of "confidence," sometimes the supply of money or capital. Sometimes, possibly, it may be the supply of steel, which was restricted in the latter part of 1919 by the steel strike, followed by the bituminous coal strike. In the next few months industrial activity will be limited only by two influences—supply of transportation and supply of labor. Transportation limitation is merely a possibility, not a probability. Labor limitation is a certainty. In the past few months there have been restrictions in outdoor work and the steel mills have had a fairly good labor supply, resulting in heavy production and deliveries. The steel has not all been consumed, some of it being accumulated against spring requirements. Steel production has acquired a margin of safety over steel consumption. Much of the willingness of steel buyers to take deliveries so freely of late and at the present time is due in part at least to the fact that on the whole the deliveries are at prices much below those now ruling, being against old orders or contracts. There is much more chance, for the next few months, of steel consumption being restricted by labor supply than of steel supplies falling short of actual consuming capacity.

Prices Advance

The minimum market price on bars, shapes and plates has advanced in the week from 2.20c. to 2.25c. The 2.25c. price seems to have been an objective of some conservative sellers and the chances seem to be that the general basis of the market will not advance farther, higher prices, if obtained, being on early deliveries and thus representing a delivery premium rather than a general advance. Possibly the same observation may be made of finished steel prices in general.

The advancing tendency in the independent market for sheets, the Steel Corporation having been sold out through June and therefore not being a factor, has crystallized on definite prices at which a number of independents have opened order books for shipment after April 1. These prices now represent the sheet market, and are as follows: Blue annealed, 2.75c., base, on 12 gage and heavier and 2.90c., base, on 13 gage and lighter; black sheets, 3.60c.; galvanized sheets, 4.75c.; automobile sheets, 5.25c. Splitting the blue annealed list is an innovation, making the advance over old prices \$5@\$8 a ton according to gage. Black sheets advance \$5 a ton and galvanized sheets \$8, the spread being increased on account of the high price of zinc, while difficulty in securing labor for galvanizing departments is also a factor. The price of independent producers of automobile sheets had been 5c., so that there is an advance of \$5 a ton in the independent market, but the Steel Corporation had not advanced above its old price of 4.70c., at which it is sold practically through June.

By a weighted average, finished steel prices are now 60 per cent above their 1913 average, or at 160 using 1913 as 100. The Bureau of Labor's index number of commodities at wholesale, on this basis, has been at 156 for the past three monthly announcements. Last week Secretary Mellon was reported as expressing the opinion that the general advance in commodity prices, with the exception of steel, had probably ended. The present outlook is that steel may not advance farther, except for the development of delivery premiums, involving only small tonnages. As a matter of fact, the great bulk of the present mill deliveries is at much below current market prices.

Coke and Pig Iron

The Connellsville coke market has developed a new line. The common belief had been that the declining tendency marked since the first of the year would continue until the market should reach a level commensurate with old prices with allowance for higher wages now paid. Demand for domestic consumption was expected to disappear this month, causing a decline of its own. Furnaces having contracts for the current quarter intended to defer as long as possible negotiating contracts for second quarter.

The coke market has turned, losing its prospect of further decline and becoming strong. The chief factor apparent is that two steel companies in Youngstown, Republic Iron & Steel Co. and Youngstown Sheet & Tube Co., have bought Connellsville coke to July 1, paying \$7 for most of the tonnage and \$6.75 for a smaller part. The particular point is that these companies have by-product coking capacity sufficient to cover normal requirements of their blast furnaces, but under forced operation they require a little outside coke. The tonnage bought by the two companies is 29,000 tons a month. Two or three months ago these steel interests were willing if not anxious to sell basic pig iron, thus competing with merchant furnaces. Now they buy coke in the market patronized by merchant furnaces and thus become their competitors in the purchase of raw materials. There is an interesting reversal of the force applied upon the merchant pig iron market. The merchant furnaces now see that coke will cost them more for second quarter than was expected. The pig-iron market has already strengthened materially, basic and foundry being quotable \$1 a ton higher than a week ago. The market now stands at \$28 for bessemer, \$27 for basic and \$28 for foundry, at valley furnaces, with \$1.77 freight to Pittsburgh. It may easily advance a couple of dollars a ton within a month.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 36 – $0 38

Sulphuric, 66°, tanks	ton	14 50 – 15 00
Sulphuric, 66° drums	ton	19 00 – 20 00
Tannic, U.S.P., bbl.	lb.	65 – 70
Tannic, tech, bbl	lb.	.40 – 45
Tartaric, imp. crys, bbl	lb	30½ – 31
Tartaric, imp, powd, bbl.	lb.	31 – 32
Tartaric, domestic, bbl	lb	– 32
Tungstic, per lb of WO_3	lb	1 00 – 1 20
Alcohol, butyl, drums	gal	.18 – 23
Alcohol ethyl (Cologne spirit), bbl	gal	4.75 – 4 95
Alcohol, methyl (see Methanol)		
Alcohol, denatured, 188 proof No. 1	gal.	.38 – 40
Alum, ammonia, lump, bbl	lb.	.03½ – 03¾
Potash, lump, bbl	lb	.03 – 03½
Chrome, lump, potash, bbl.	lb.	.05 – 05½
Aluminum sulphate, com, bags	100 lb.	1.50 – 1 65
Iron free bags	lb.	.02¼ – .02½
Aqua ammonia, 26°, drums	lb.	.06½ – 07½
Ammonia, anhydrous, cyl	lb.	.30 – 30½
Ammonium carbonate, powd casks, imported	lb.	.09½ – 10
Ammonium carbonate, powd domestic, bbl	lb.	.13 – .14
Ammonium nitrate, tech, casks	lb.	10 – 11
Amyl acetate tech., drums	gal	2 80 – 3 05
Arsenic, white, powd, bbl	lb	15½ – 16
Arsenic, red, powd, kegs	lb.	.13 – 13½
Barium carbonate, bbl	ton	70 00 – 75 00
Barium chloride, bbl.	ton	87 00 – 95 00
Barium dioxide, drums	lb.	.18 – 18½
Barium nitrate, casks		08½ – 08¾
Barium sulphate, bbl...	lb.	04 – 04½
Blanc fixe, dry, bbl	lb	.04 – 04½
Blanc fixe, pulp, bbl	ton	45 00 – 55 00
Bleaching powder, f.o.b. wks., drums	100 lb	2 20 – 2 50
Resale drums	100 lb	2 50 – 2 75
Borax, bbl.	lb.	05½ – 05¾
Bromine, cases	lb.	25 – 27
Calcium acetate, bags	100 lb.	3 50 – 3 60
Calcium carbide, drums	lb.	04½ – 04¾
Calcium chloride, fused, drums	ton	22 00 – 23 00
Gran drums	lb.	.01½ – 01¾
Calcium phosphate, mono, bbl.	lb	06½ – 07
Camphor, cases	lb.	.91 – 93
Carbon bisulphide, drums	lb.	.07 – 07½
Carbon tetrachloride, drums	lb.	.09½ – .10
Chalk, precip domestic, light, bbl	lb.	.04½ – 04¾
Domestic, heavy, bbl	lb.	.03½ – 03¾
Imported, light, bbl	lb.	.04½ – 05
Chlorine, liquid, cylinders	lb.	06 – 06½
Chloroform, tech, drums	lb.	35 – 38
Cobalt oxide, bbl	lb.	2 10 – 2 25
Copperas, bulk, f.o.b. wks.	ton	16 50 – 20 00
Copper carbonate, bbl	lb	.19 – 20
Copper cyanide, drums	lb	.47 – 50
Copper sulphate, crys., bbl	100 lb.	6.40 – 6 50
Cream of tartar, bbl	lb.	.24 – 25
Dextrine, corn, bags	100 lb.	3.25 – 3 50
Epsom salt, dom., tech, bbl.	100 lb.	2.00 – 2.25
Epsom salt, imp, tech, bags	100 lb.	1.10 – 1.25
Epsom salt, U.S.P., dom., bbl.	100 lb.	2.50 – 2.75
Ether, U.S.P., drums	lb.	.13 – .15
Ethyl acetate, com., 85%, drums	gal.	.80 – .85
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	.95 – 1.00
Formaldehyde, 40%, bbl	lb	$0 15 – $0 16½
Fullers earth, f.o.b. mines	net ton	16 00 – 17 00
Fullers earth – imp., powd	net ton	30 00 – 32 00
Fusel oil, ref, drums	gal	3 55 – 4 05
Fusel oil, crude, drums	gal	2 30 – 2 40
Glaubers salt, wks, bags	100 lb	1 20 – 1 40
Glaubers salt, imp, bags	100 lb	1 00 – 1 25
Glycerine, c.p., drums extra	lb	18½ – 19
Glycerine, dynamite, drums	lb.	17 – 17½
Iodine, resublimed	lb	4 40 – 4 50
Iron oxide, red, casks	lb.	.12 – .18
Lead:		
White, basic cabonate, dry, casks	lb.	.09½ – 10
White, in oil, kegs.	lb.	12 – 13½
Red, dry casks	lb	11¼ – 11¾
Red, in oil, kegs	lb	13 – 14½
Lead acetate, white crys., bbl.	lb	13 – 13½
Lead arsenate, powd, bbl	lb	23 – 24
Lime Hydrated, bbl	per ton	16 80 – 17 00
Lime, Lump, bbl	280 lb	3 63 – 3 65
Litharge, comm, casks	lb	.10½ – 10¾
Lithophone, bbl	lb	06½ – 07
Magnesium carb., tech, bags	lb	08 – 08½
Methanol, 95%, bbl	gal	1 23 – 1 25
Methanol, 97%, bbl	gal	1 25 – 1 27
Nickel salt, double, bbl	lb	10 – 10½
Nickel salts, single, bbl	lb	11 – 11½
Phosgene		69 – .75
Phosphorus, red, cases	lb.	.35 – .40
Phosphorus, yellow, cases	lb.	.30 – 35
Potassium bichromate, casks	lb.	.09¾ – 10
Potassium bromide, gran, bbl	lb.	.16 – 23
Potassium carbonate, 80-85%, calcined, casks	lb.	.05¾ – 06
Potassium chlorate, powd	lb	07 – 08
Potassium cyanide, drums	lb.	.45 – .50
Potassium hydroxide (caustic potash) drums	100 lb	7 35 – 7 50
Potassium iodide, cases	lb	3 50 – 3 60
Potassium nitrate, bbl	lb	.06½ – .07
Potassium permanganate, drums	lb.	.19½ – .20
Potassium prussiate, red, casks	lb.	.80 – .85
Potassium prussiate, yellow, casks	lb.	37½ – 38
Salammoniac, white, gran, casks, imported	lb.	06½ – .06¾
Salammoniac, white, gran, bbl, domestic	lb.	.08 – .08½
Gray, gran, casks	lb.	08½ – .08¾
Salsoda, bbl	100 lb.	1.20 – 1 40
Salt cake (bulk)	ton	26 00 – 28.00
Soda ash, light, 58% flat, bags, contract	100 lb.	1.60 – 1.67
Soda ash, light, basis, 48%, bags, contract, f.o.b. wks	100 lb.	1.20 – 1.30
Soda ash, light, 58%, flat, bags, resale	100 lb.	1 75 – 1.80
Soda ash, dense, bags, contract, basis 48%	100 lb.	1.17½ – 1.20
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90
Soda, caustic, 76%, solid, drums, f.a.s	100 lb.	3.45 – 3 70
Soda, caustic, 76%, solid, drums, contract	100 lb.	3 35 – 3 40
Soda, caustic, basis 60%, wks, contract	100 lb.	2.50 – 2.60
Soda, caustic, ground and flake, contracts	100 lb.	3.80 – 3.90
Soda, caustic, ground and flake, resale	100 lb.	4.00 – 4 15
Sodium acetate, works, bags	lb.	06 – .06½
Sodium bicarbonate, bbl	100 lb.	2.00 – 2 50
Sodium bichromate, casks	lb	07¾ – .08
Sodium bisulphate (niter cake)	ton	6.00 – 7.00
Sodium bisulphite, powd., U.S.P., bbl	lb.	.04½ – .04¾
Sodium chlorate, kegs	lb.	06½ – 07
Sodium chloride	long ton	12 00 – 13 00
Sodium cyanide, cases	lb.	.20 – .23
Sodium fluoride, bbl.	lb.	.09 – .10
Sodium hyposulphite, bbl.	lb.	03 – 03½
Sodium nitrite, casks	lb.	08½ – .09
Sodium peroxide, powd, cases	lb.	.28 – .30
Sodium phosphate, dibasic, bbl.	lb.	.03¾ – .04
Sodium prussiate, yel. drums	lb.	.19 – .20
Sodium silicate (40°, drums)	100 lb.	.80 – 1.15
Sodium silicate (60°, drums)	100 lb.	2.00 – 2.25
Sodium sulphide, fused, 60-62% drums	lb.	.04 – .04½
Sodium sulphite, crys., bbl.	lb.	.03½ – .03¾
Strontium nitrate, powd., bbl.	lb.	.09½ – .10½
Sulphur chloride, yel drums.	lb.	.04½ – .05
Sulphur, crude	ton	18.00 – 20.00
Sulphur dioxide, liquid, cyl.	lb.	.08 – .08½
Sulphur, flour, bbl.	100 lb.	2.35 – 3.15
Sulphur, roll, bbl.	100 lb.	$2 00 – $2 50
Talc—imported, bags	ton	30 00 – 40 00
Talc—domestic powd, bags.	ton	18 00 – 25 00
Tin bichloride, bbl	lb.	11 – 11½
Tin oxide, bbl	lb.	.47 – 48
Zinc carbonate, bags	lb.	14 – .14½
Zinc chloride, gran, bbl	lb.	06 – 07
Zinc cyanide, drums	lb.	.37 – 38
Zinc oxide, XX, bbl	lb.	07½ – 08
Zinc sulphate, bbl.	100 lb.	2 75 – 3 00

Coal-Tar Products

Alpha-naphthol, crude, bbl	lb.	$0 80 – $0.85
Alpha-naphthol, ref, bbl	lb.	1 05 – 1.10
Alpha-naphthylamine, bbl	lb.	.27 – .30
Aniline oil, drums	lb.	.16½ – .17
Aniline salts, bbl	lb.	.24 – .25
Anthracene, 80%, drums	lb.	.75 – 1.00
Anthracene, 80%, imp, drums, duty paid	lb.	.65 – .70
Anthraquinone, 25%, paste, drums	lb.	.70 – .75
Benzaldehyde U.S.P., carboys	lb.	1.40 – 1.45
Benzene, pure, water-white, tanks and drums	gal.	30 – .35
Benzene, 90%, tanks & drums	gal.	.26 – .32
Benzene, 90%, drums, resale	gal.	.32 – .34
Benzidine base, bbl	lb.	.85 – .90
Benzidine sulphate, bbl	lb.	.75 – .80
Benzoic acid, U.S.P., kegs	lb	.72 – .75
Benzoate of soda, U.S.P., bbl.	lb.	.57 – .65
Benzyl chloride, 95-97%, ref., drums	lb.	.25 – .27
Benzyl chloride, tech, drums	lb.	.20 – .23
Beta-naphthol, subl, bbl	lb.	.55 – .60
Beta-naphthol, tech, bbl	lb.	.24 – .25
Beta-naphthylamine, tech	lb.	1.00 – 1.25
Carbazol, bbl	lb.	.75 – .90
Cresol, U.S.P., drums.	lb.	.25 – .29
Ortho-cresol, drums	lb.	.24 – .26
Cresylic acid, 97%, resale, drums	gal.	1.50 – 1 75
95-97%, drums, resale	gal.	1.50 – 1.75
Dichlorbenzene, drums	lb.	.07 – .09
Diethylaniline, drums	lb.	.50 – .60
Dimethylaniline, drums	lb.	.41 – .42
Dinitrobenzene, bbl	lb.	.20 – .22
Dinitroclorbenzene, bbl.	lb.	.22 – .23
Dinitronaphthalene, bbl.	lb.	.30 – .32
Dinitrophenol, bbl	lb.	.35 – .40
Dinitrotoluene, bbl	lb.	.22 – .24
Dip oil, 25%, drums	gal.	.25 – .30
Diphenylamine, bbl.	lb.	.53 – .55
H-acid, bbl.	lb.	.80 – .85
Meta-phenylenediamine, bbl.	lb.	.95 – 1.00
Michlers ketone, bbl	lb.	3.00 – 3.50
Monochlorbenzene, drums	lb.	.08 – .10
Monoethylaniline, drums	lb.	.95 – 1.10
Naphthalene, crushed, bbl.	lb.	.05½ – .06
Naphthalene, flake, bbl.	lb.	.06 – .06½
Naphthalene, balls, bbl.	lb.	.07 – .07½
Naphthionate of soda, bbl.	lb.	.58 – .65
Naphthionic acid, crude, bbl.	lb.	.60 – .65
Nitrobenzene, drums	lb.	.10 – .12
Nitro-naphthalene, bbl.	lb.	.30 – .35
Nitro-toluene, drums.	lb.	.15 – .17
N-W acid, bbl	lb.	1.15 – 1.20
Ortho-amidophenol, kegs	lb.	2.30 – 2.35
Ortho-dichlorbenzene, drums	lb.	.17 – .20
Ortho-nitrophenol, bbl.	lb.	.90 – .92
Ortho-nitrotoluene, drums	lb.	.10 – .12
Ortho-toluidine, bbl.	lb.	.13 – .15
Para-amidophenol, base, kegs	lb.	1.15 – 1.20
Para-amidophenol, HCl, kegs	lb.	1.20 – 1.25
Para-dichlorbenzene, bbl.	lb.	.17 – .20
Paranitraniline, bbl	lb.	.74 – .75
Para-nitrotoluene, bbl.	lb.	.55 – .65
Para-phenylenediamine, bbl.	lb.	1.50 – 1.55
Para-toluidine, bbl	lb.	.85 – .90
Phthalic anhydride, bbl.	lb.	.35 – .38
Phenol, U.S.P., drums	lb.	.34 – .35
Picric acid, bbl	lb.	.20 – .22
Pyridine, dom, drums	gal.	nominal
Pyridine, imp, drums	gal.	2 30 – 2.50
Resorcinol, tech., kegs	lb.	1.50 – 1.55
Resorcinol, pure, kegs	lb.	2.00 – 2.10
R-salt, bbl.	lb.	.55 – .60
Salicylic acid, tech, bbl.	lb.	.40 – .42
Salicylic acid, U.S.P., bbl.	lb.	.45 – .47
Solvent naphtha, water-white, drums	gal.	.37 – .40
Crude, drums	gal.	.22 – .24
Sulphanilic acid, crude, bbl.	lb.	.18 – .20
Thiocarbanilide, kegs	lb.	.35 – .38
Toluidine, kegs	lb.	1.20 – 1.30
Toluidine, mixed, kegs	lb.	.30 – .35
Toluene, tank cars	gal.	.35 – .37
Toluene, drums	gal.	.40 – .43
Xylidines drums	lb.	.40 – .45
Xylene, pure, drums	gal.	.45 – .50
Xylene, com., drums	gal.	.40 – .42
Xylene, com., ta...	gal.	.30 – ....

Naval Stores

Rosin B-D, bbl.	280 lb.	$6 00 –	
Rosin E-I, bbl.	280 lb.	6 10 –	$6 25
Rosin K-N, bbl.	280 lb.	6 40 –	6 80
Rosin W.G.-W.W., bbl.	280 lb.	7 25 –	7 95
Wood rosin, bbl	280 lb.	6 25 –	
Turpentine, spirits of, bbl	gal.	1 51 –	1 52
Wood, steam dist., bbl.	gal.	1 35 –	
Wood, dest. dist., bbl.	gal.	1 25 –	
Pine tar pitch, bbl.	200 lb.	–	6 00
Tar, kiln burned, bbl.	500 lb.	–	12 00
Retort tar, bbl.	500 lb.	–	11 00
Rosin oil, first run, bbl.	gal.	.43	
Rosin oil, second run, bbl.	gal.	.47 –	...
Rosin oil, third run, bbl.	gal.	.53 –	
Pine oil, steam dist	gal.	–	90
Pine oil, pure, dest. dist.	gal.	–	85
Pine tar oil, ref.	gal.	–	.46
Pine tar oil, crude, tanks f.o.b. Jacksonville, Fla	gal.	–	35
Pine tar oil, double ref, bbl.	gal.	–	75
Pine tar, ref., thin, bbl	gal.	–	25
Pinewood creosote, ref, bbl.	gal.	–	52

Vegetable Oils

Castor oil, No 3, bbl	lb	$ 12¾ –	$ 13
Castor oil, AA, bbl	lb	.13¼ –	13½
Chinawood oil, bbl.	lb.	.18½ –	18¾
Coconut oil, Ceylon, bbl.	lb	09½ –	9¾
Coconut oil, Cochin, bbl.	lb.	09¾	10
Corn oil, crude, bbl	lb	.11¼ –	.11½
Cottonseed oil, crude (f.o.b. mill), tanks	lb.	10 –	10
Summer yellow, bbl.	lb.	.12 –	12¼
Winter yellow, bbl	lb	13	13¼
Linseed oil, raw, car lots, bbl.	gal	98 –	99
Raw, tank cars (dom.)	gal.	94 –	95
Boiled, 5-bbl lots (dom)	gal	1 02	1 04
Olive oil, denatured, bbl.	gal	1 10 –	1 15
Palm, Lagos, casks	lb	08 –	08¼
Palm kernel, bbl	lb	.08¾ –	09
Peanut oil, crude, tanks (mill)	lb.	.13½ –	.13¾
Peanut oil, refined, bbl	lb.	16 –	16½
Rapeseed oil, refined, bbl	gal	.85 –	86
Rapeseed oil, blown, bbl	gal	90 –	91
Soya bean (Manchurian), bbl	lb	.12 –	
Tank, f.o.b. Pacific coast	lb	.10⅛	

Fish Oils

Menhaden, light pressed, bbl.	gal	$0.60 –	
White bleached, bbl	gal	64 –	65
Blown, bbl	gal.	68 –	69
Whale No 1 crude, tanks, coast	lb	06 –	06½

Dye & Tanning Materials

Divi-divi, bags	ton	$38 00	$39 00
Fustic, sticks	ton	30 00	35 00
Fustic, chips, bags	lb	04 –	05
Logwood, sticks	ton	28 00 –	30 00
Logwood, chips, bags	lb.	02½ –	03½
Sumac, leaves, Sicily, bags	ton	65 00 –	
Sumac, ground, bags.	ton	55 00 –	60 00
Sumac, domestic, bags	ton	35 00 –	
Tapioca flour, bags.	lb	03¾	05

EXTRACTS

Archil, conc, bbl	lb	$0 17	$0 18
Chestnut, 25% tannin, tanks	lb	02 –	03
Divi-divi, 25% tannin, bbl	lb	04 –	05
Fustic, crystals, bbl	lb	20 –	22
Fustic, liquid, 42°, bbl	lb	08 –	09
Gambier, liq, 25% tannin, bbl.	lb.	08 –	09
Hematine crys, bbl	lb.	14	18
Hemlock, 25% tannin, bbl	lb	04 –	05
Hypernic, solid, drums	lb	.24 –	26
Hypernic, liquid, 51°, bbl.	lb	14 –	17
Logwood, crys., bbl	lb	19 –	20
Logwood, liq, 51°, bbl	lb	09 –	10
Quebracho, solid, 65% tannin, bbl.	lb.	.04½ –	05
Sumac, dom., 51°, bbl.	lb.	.06½ –	07

Waxes

Bayberry, bbl.	lb.	$0 28 –	$0 30
Beeswax, refined, dark, bags	lb.	30 –	32
Beeswax, refined, light, bags.	lb	34 –	35
Beeswax, pure white, cases.	lb	40 –	41
Candelilla, bags	lb	33 –	34
Carnauba, No. 1, bags	lb	.38 –	40
No. 2, North Country, bags	lb	.24 –	24½
No. 3, North Country, bags	lb.	17½ –	18½
Japan, cases	lb.	15 –	15½
Montan, crude, bags.	lb	.03½ –	.04
Paraffine, crude, match, 105-110 m p.	lb.	.04 –	04½
Crude, scale 124-126 m.p., bags	lb.	.02½ –	.02¾
Ref., 118-120 m.p, bags	lb.	.03⅛ –	.03½
Ref., 125 m p, bags	lb.	.03½ –	.03¾
Ref. 128-130 m.p., bags	lb.	.04 –	.04¼
Ref., 133-135 m.p., bags.	lb.	.04½ –	.04¾
Ref., 135-137 m.p., bags	lb.	05 –	05½
Stearic acid, sgle pressed, bags	lb	.10 –	10½
Double pressed, bags	lb.	.10½ –	.10¾
Triple pressed, bags	lb	.11 –	11½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb.	$3 20 –	$3 25
F.a.s double bags	100 lb.	3 85 –	3 95
Blood, dried, bulk	unit	4.60 –	
Bone, raw, 3 and 50, ground	ton	30.00 –	35 00
Fish scrap, dom., dried, wks.	unit	5 00 –	5.10
Nitrate of soda, bags	100 lb.	2.60 –	2.65
Tankage, high grade, f.o.b. Chicago	unit	4.70 –	4 80

Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	$3.50 –	$4 00
Tennessee, 78-80%	ton	7 00 –	8 00
Potassium muriate, 80%, bags	ton	35 00 –	36 00
Potassium sulphate, bags	unit	1 00 –	

Crude Rubber

Para—Upriver fine	lb	$0 33 –	$0.33½
Upriver coarse	lb	27½ –	.28
Upriver caucho ball	lb	29½ –	30
Plantation—First latex crepe	lb	35½ –	35¾
Ribbed smoked sheets	lb	.35½ –	.35¾
Brown crepe, thin, clean	lb	31 –	32
Amber crepe No 1	lb	31 –	32

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$450 00 –	$550 00
Asbestos, shingle, f.o.b., Quebec	sh ton	60 00 –	80 00
Asbestos, cement, f.o.b., Quebec	sh ton	15 00 –	17 00
Barytes, grd, white, f.o.b mills, bbl	net ton	16 00 –	20 00
Barytes, grd., off-color, f.o.b. mills bulk	net ton	13 00 –	21 00
Barytes, floated, f.o.b St Louis, bbl	net ton	24 00 –	28 00
Barytes, crude f.o.b mines, bulk	net ton	8 50 –	9 00
Casein, bbl, tech	lb	11 –	12
China clay (kaolin) crude, f.o.b Ga	net ton	7 00 –	9 00
Washed, f.o.b Ga	net ton	8 00 –	9 00
Powd, f.o.b Ga	net ton	13 00 –	20 00
Crude f.o.b Va	net ton	8 00 –	12 00
Ground, f.o.b Va	net ton	13 00 –	20 00
Imp, lump, bulk	net ton	15 00 –	20 00
Imp, powd	net ton	45 00 –	50 00
Feldspar, No. 1 pottery	long ton	6 00 –	7 00
No. 2 pottery	long ton	5 00 –	5 50
No 1 soap	long ton	7 00 –	7 50
No. 1 Canadian, f.o.b mill	long ton	25 00 –	27 00
Graphite, Ceylon, lump, first quality, bbl	lb	06 –	.06½
Ceylon, chip, bbl	lb	05 –	05½
High grade amorphous crude	ton	35 00 –	50 00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN—The Alabama Co., Union Trust Bldg., Baltimore, Md., E. N. Rich, president, has acquired a tract of property totaling about 100 acres on the Shinbone Ridge, near Gadsden, comprising extensive iron ore properties, and plans for large development work. A plant will be installed at an early date.

Arizona

MIAMI—The Inspiration Copper Co. will commence immediately the construction of an addition to its mill. A contract for the steel frame work has been awarded.

California

LOS ANGELES—The California Paint Remover Co., 712 Crocker St., is planning for the erection of a new 1-story plant on 11th St., to be 115x160 ft., estimated to cost close to $30,000, with equipment.

LODI—The American-Mexican Ramie Co. has tentative plans under consideration for the erection of a new local plant for fiber refining for commercial service. G. W. Schlichten is president.

LOS ANGELES—The Mexican Petroleum Co., 120 Broadway, New York, N. Y., has acquired property at Los Angeles Harbor, and plans for the construction of a new oil refinery. It will consist of a number of buildings and is estimated to cost in excess of $6,000,000, with machinery. E. L. Doheny, Los Angeles, is president.

HUNTINGTON BEACH—The Pacific Gasoline Co., Los Angeles, is planning for the construction of a large gasoline absorption plant on local site recently acquired. The plant will be operated for gasoline production in co-operation with the Amalgamated Oil Co., and is estimated to cost more than $100,000. W. J. Bower is president and general manager. E. T. Hitchcock will be in charge of construction.

OAKLAND—The Western Rock Products Co., Balboa Bldg., San Francisco, has acquired property at the foot of 85th Ave., Oakland, as a site for the erection of a new plant for the manufacture of pigments and other paint ingredients. Plans will be drawn at once.

LOS ANGELES—The Pacific Coast Borax Co., Kohl Bldg., San Francisco, is taking bids on a general contract for the erection of the first unit of its proposed new refining plant at Los Angeles Harbor, estimated to cost approximately $500,000. The installation will include a power plant and machine shop. Albert C. Martin, Higgins Bldg., Los Angeles, is architect.

Connecticut

SOUTHBURY—Fire, Feb. 15, destroyed a portion of the local paper-manufacturing plant of the Diamond Match Co., 111 Broadway, New York, N. Y., with loss estimated at $100,000, including equipment. It is planned to rebuild.

HARTFORD—The Hartford City Gas Light Co., 565 Main St., will commence immediately the erection of a reinforced concrete addition to its artificial gas plant, estimated to cost approximately $35,000. Buck & Sheldon, 60 Prospect St., Hartford, are engineers.

Florida

SARASOTA—J. D. Hazen is planning for the erection of a new 1-story foundry in connection with a new marine repair plant to be constructed in the Hog Creek Basin section.

EUSTIS—The A. J. Wolz Sons Co., operating a local brick-manufacturing plant, will make a number of additions and improvements, including the installation of additional machinery.

MIAMI—The Sun Oil Co. will install a new storage and distributing plant on site at Alton Rd. and Third St., estimated to cost approximately $50,000.

Georgia

HELEN—The Smethport Extract Co., Damascus, Va., has purchased property near Helen heretofore held by the Morse Brothers Lumber Co., and plans for the early erection of a new plant for the production of tannic acid for leather tanning and other service. It will cost about $25,000.

Illinois

ROCK ISLAND—The Servus Rubber Co., 101 Central Park Bldg., has tentative plans under consideration for the erection of an addition to its plant for considerable increase in capacity. It is expected to build five new factory units. J. J. Adams is president.

CHICAGO—The Hoffman Brothers Tanning Co., 1701 Grand Ave., has taken bids and will soon award a general contract for the erection of a 2-story and basement addition, 25x100 ft., at Grand and Kilpatrick Aves. August C. Wilmanns, 38 South Dearborn St., is architect. C. D. Hoffman is president.

Indiana

EVANSVILLE—The Best Brick Co. is planning for extensions in its plant for increased output. Machinery to cost about $12,000 will be installed.

SHELBYVILLE—The Kennedy Car Liner & Bag Co. has awarded a contract to the H. K. Ferguson Co., Cleveland, O., for the erection of a new plant, 250x100 ft., for the manufacture of paper products, to replace a portion of its works recently destroyed by fire. The structure is estimated to cost about $100,000, including equipment. Fred W. Kennedy is president.

Kansas

PERU—The Mid-Continent Clay Co. is arranging for the discontinuance of face-brick manufacture, and will devote its entire plant to the production of burned clay roofing tile and tile slabs. Necessary facilities will be installed for the change.

Kentucky

ASHLAND—The American Rolling Mill Co. is arranging for the immediate rebuilding of its chemical laboratory at the local works, destroyed by fire, Feb. 12. Headquarters of the company are at Middletown, Ohio.

Louisiana

ELIZABETH—The Calcasieu Mfg. Co. has construction under way on a new local paper mill and plans to install machinery at an early date. The plant will be ready for service in the spring. It is estimated to cost in excess of $75,000.

Maryland

BALTIMORE—The Piccadilly Ink Co., recently incorporated with a capital of $100,000, to manufacture writing and other inks, has acquired the 3-story building, 25x30 ft., at 872 Linden Ave., for a new plant and will take immediate possession. A large portion of the structure will be given over to analytical laboratories, and equipment will be installed at once. R. F. Humphries, Jr., is president, and E. H. Wight, director.

BALTIMORE—The Board of Awards office of the City Register, City Hall, will receive bids until March 7 for additions to the Monte-Bello filtering plant at the municipal waterworks, as per plans and specifications at the office of William A. Megraw, Room 204, City Hall, Baltimore, water engineer.

Michigan

ST. JOSEPH—Frank S. Bicking, West Chester, Pa., formerly an official of the S. Austin Bicking Paper Co., East Downingtown, Pa., has acquired the plant and property of the Mullen Brothers Paper Co., St. Joseph, at a sale in bankruptcy, for a consideration said to be in excess of $93,000. The new owner is said to be planning for the organization of a new company to take over and operate the plant. A number of improvements will be made.

Minnesota

ST. PAUL—The Waldorf Paper Products Co., Hampden and Wabash Aves., is completing plans and will take bids early in March, for the erection of a new plant at Hampden and Myrtle Aves., to be 5-story, 83x250 ft., estimated to cost approximately $250,000, including machinery. H. A. Sullwold, 611 Endicott Bldg., St. Paul, is architect.

Missouri

ASH GROVE—The Ash Grove Lime & Portland Cement Co. is planning for improvements at its plant, including the erection of a new power house, estimated to cost about $75,000.

Massachusetts

PEABODY—The Griess-Pfleger Tanning Co., 810 Sycamore St., Cincinnati, O., has acquired the local tanning plant of J. T. O'Shea. The structure was recently completed and has never been occupied. The new owner plans for the immediate installation of machinery and will operate as a branch tannery for the production of finished calfskin. It is purposed to develop an output of 250 doz. calfskins daily.

Nebraska

OMAHA—Armour & Co., Union Stock Yards, Chicago, Ill., are considering plans for the rebuilding of the portion of their packing plant at South Omaha, destroyed by fire, Feb. 15, with loss reported in excess of $1,500,000, including lard refineries and other structures.

New Jersey

NEWARK—The Anglo-American Varnish Co., 53 Johnston Ave., has filed plans for the erection of an addition to its plant to cost about $22,000. Fred A. Phelps, Union Bldg., is architect.

BAYONNE—The Ingram Richardson Mfg. Co., Beaver Falls, Pa., manufacturer of porcelain enameled iron signs, etc., has awarded a contract to James Mitchell, Inc., 999 Bergen Ave., Jersey City, N. J., for the erection of its proposed new local plant, to be 1-story, reinforced-concrete, 181x321 ft. Work will be placed under way at once. The A. M. Allen Co., 7016 Euclid Ave., Cleveland, O., is architect and engineer.

TRENTON—The General Chinaware Corp., 15 Broad St., New York, N. Y., recently organized to manufacture sanitary earthenware products, has acquired the former local plant of the New Jersey Chinaware Co., and will conduct operations at this location. Extensive production is planned; improvements will be made in the plant.

KEARNY—Swift & Co., Harrison Turnpike, are planning for the rebuilding of the laboratory at their local meat-packing plant, destroyed by fire, Feb. 8, with loss reported at $8,000. Headquarters of the company are at the Union Stock Yards, Chicago, Ill.

New York

BUFFALO—The Mineral Potash Corp., care of J. P. Andrews & Co., 514 Brisbane Bldg., is planning for the installation of a commercial feldspar plant, including grinding, crushing and pulverizing machinery, tramway, air compressors and auxiliary equipment. To provide for the installation, the company is disposing of a stock issue of $300,000, the entire proceeds to be used for this purpose.

BROOKLYN—Gerstendorfer Brothers, 231 East 42nd St., manufacturers of bronze powders, etc., have awarded a contract to the John W. Ferguson Co., United Bank Bldg., Paterson, N. J., for the erection of their proposed new plant at Clinton and Lorraine Sts., Brooklyn, to be 1-story, 25x200 ft., with three 1-story structures adjoining, 40x41 ft., 40x45 ft. and 30x500 ft. The last noted will be equipped for the manufacture of varnishes. The new plant is estimated to cost $385,000, including machinery. Russell G. Cory, 30 Church St., New York, is architect and engineer. Edward Eckart heads the company.

Ohio

PORT CLINTON—The American Gypsum Co. is considering plans for the erection of a new mill at its local plant, estimated to cost approximately $100,000, including machinery. F. J. Griswold is in charge.

PORTSMOUTH—Plans are nearing completion for the construction of a new 1-story foundry, 100x300 ft., at the plant of the

Ohio Stove Co., estimated to cost $75,000, to be used for the production of iron castings. The Austin Co., Euclid Ave, Cleveland, is engineer and contractor.

ASHTABULA—The Ashtabula Gas Co., in conjunction with the local city council and the Northeastern Oil & Gas Co, has preliminary plans in progress for the construction of a new artificial gas plant for local and neighboring service, estimated to cost close to $1,000,000. F W. Stone, manager, is in charge

Oklahoma

COLGATE—The Western Carbon Co is selecting a site in Coal County for the construction of a new plant for the production of carbon black, estimated to cost about $350,000, with machinery. Roy C. Morrison is local representative

OKLAHOMA CITY—The Noble Oil & Gas Co has acquired a local oil-refining plant and plans for extensions and improvements, including the installation of additional equipment

Oregon

HUNTINGTON—The Sun Portland Cement Co has work in progress on the first unit of its proposed new local cement mill, estimated to cost in excess of $100,000, and plans to place the plant in service at the earliest date It is proposed to build two other plant units in the near future Headquarters of the company are at Portland, Ore

Pennsylvania

LEHIGHTON—The Aluminum Pigment & Products Co will commence immediately the construction of a new 1-story plant

PHILADELPHIA—The Bisbee Linseed Co, Drexel Bldg, has filed plans for the construction of a new 1-story building at Delaware Ave and Bigler St, to cost about $15,000

QUAKERTOWN The Krupp Foundry Co, Inc, Lansdale, Pa., manufacturer of cast-iron pipe, has acquired a local site for the erection of a new 1-story foundry, 125x200 ft, to be operated as a branch plant Bids for construction will be taken at once

BOWMANSVILLE—The Prince Metallic Paint Co will make enlargements in its plant for considerable increase in production Additional machinery will be installed

YORK—William H Grothe, Boundary Ave, operating a brick-manufacturing plant, will remodel and improve the works Additional machinery will be installed to double, approximately, the present output

WILKES-BARRE—Abraham Gast has acquired the local plant of the Wyoming Tire & Rubber Co at a receiver's sale. The new owner is said to be planning for the organization of a company to operate the factory

Tennessee

NASHVILLE The Hermitage Portland Cement Co, Chattanooga, has perfected plans for the immediate erection of its proposed new plant on site near Nashville, to have an initial daily output of 2,000 bbl It will consist of a number of buildings and is estimated to cost more than $500 000, with machinery John C. Vance is president

CHATTANOOGA—The Chattanooga Stamping & Enameling Co. has commenced the installation of new electric furnaces and other equipment at its plant to cost about $30,000 The capacity will be increased approximately one-third.

MEMPHIS—Fire, Feb. 7, destroyed the building occupied by the Myers Paper Co, with loss estimated at close to $100,000 It is planned to rebuild.

PURYEAR—The Dixie Brick & Tile Co will commence immediately the construction of additions to its plant, including the installation of clay-grinding, brick-manufacturing and other machinery It is purposed to advance the capacity from 30,000 to 40,000 face-brick per day Walter H. Jackson, Calconda, Ill, is engineer in charge of construction. O A Harker, Jr., is president.

Texas

EL PASO—The Rio Grande Oil Co is planning for the construction of additions to its local oil refinery and the branch refining plant at Phoenix, Ariz; the work will include the installation of considerable new machinery. It is also expected to build a new refinery on site to be selected at Los Angeles, Calif The company has recently increased its capital from $750,000 to $1,500 000 for proposed expansion.

DALLAS—The Wax Wrap Paper Co., recently organized, has acquired a local building for the establishment of a plant for the manufacture of waxed papers. It is expected to develop an output of 10,000 lb. per day Machinery will be installed at an early date. J L Parchman is secretary.

Utah

EUREKA The Eureka Smelting & Mining Co. has plans under way for the construction of a new smelting plant at its properties, estimated to cost in excess of $400,000 The company has recently acquired the plant and properties of the Eureka-Croesus Mining Co. Frank L Torres is president.

Virginia

RICHMOND—The Wortendyke Mfg Co, East 13th St, is having preliminary plans prepared for the erection of a new plant for the manufacture of paper products, to be located in the South Richmond district. It will be 3-story, and is estimated to cost $200,000 Joseph H Wallace & Co, 5 Beekman St, New York, is engineer.

West Virginia

LUMBERPORT—The Radio Glass Co, recently organized as a subsidiary of the Mound City Glass Co, will soon commence the construction of a new plant on site adjoining the works of the parent organization The initial works will be equipped for light cutting, needle etching, plate etching and kindred service and is estimated to cost in excess of $10,000. E P. Boggess, president of the Mound City company, heads the new organization.

CHARLESTON—The Libbey-Owens Sheet Glass Co, Nicholas Bldg, Toledo, O, is taking bids for the erection of the proposed 2-story addition to its local plant, 45x200 ft., estimated to cost $300,000, including equipment The Devore Co, Nicholas Bldg, is engineer D D Libbey is president

Wisconsin

WAUKESHA—The Harvey Paper Co, 543 West Main St, plans to have work under way on a new local mill at an early date It will cost about $10,000 H C Harvey is president

Capital Increases, etc.

THE PORTSMOUTH COTTON OIL & REFINING CO, Portsmouth, Va, has filed notice of increase in capital from $1,750,000 to $2,000,000, for proposed expansion John Aspergren is president

THE NEW YORK GUMMED PAPER CO, 25 Dey St, New York, N Y, has arranged for an increase in capital from $5,000 to $75 000.

THE MCWANE CAST IRON PIPE CO, Birmingham Ala, has filed notice of increase in capital from $100,000 to $200,000, the proceeds to be used in part for the erection of a new plant, now in progress, and for general expansion.

THE CONTINENTAL SUGAR CO, Nasby Bldg., Toledo, O, is disposing of a bond issue of $1,700,000, a portion of the proceeds to be used for general financing and operations. C. G. Edgar is president.

THE E T MANKIN CO, INC., Richmond. Va manufacturer of clay products, has filed notice of increase in capital from $20,000 to $150,000 for general expansion, at the same time changing its name from Burroughs & Mankin, Inc.

THE AMERICAN CONCRETE PRODUCTS CO., INC, 30 North La Salle St, Chicago, Ill., has filed notice of increase in capital from $25,000 to $50,000

THE SINCLAIR CRUDE PRODUCING CO, Tulsa, Okla, affiliated with the Sinclair Refining Co, 45 Nassau St., New York, N Y, is disposing of a bond issue of $20 000,000, a portion of the proceeds to be used for extensions in oil plants and system. H L Phillips is president.

Walter C Ellis has been appointed receiver for the UNITED STATES WAXED & COATED PAPER CO, 511 Mulberry St, Newark, N. J

THE CICERO-CHICAGO CORRUGATING CO, Cicero, Ill, has filed notice of increase in capital from $100,000 to $200,000

Officials of the Air Reduction Co, 342 Madison Ave., New York, N. Y, manufacturer of commercial oxygen, acetylene, etc, and the Braun Corp, New High St., Los Angeles, Calif., manufacturer of chemical apparatus, have organized a new company to be known as the CALIFORNIA CYANIDE CO., to manufacture sodium cyanide and other chemical products. It is purposed to build a local plant. F. W. Braun has been elected president.

Industrial Developments

GLASS—The Marienville Glass Bottle Co. has commenced operations at its new plant at Marienville Pa, and will develop capacity production with a full working force. The plant represents an investment of about $75 000, and replaces a works recently destroyed by fire

Window glass-manufacturing plants in western Pennsylvania are running at full capacity and will maintain this basis of output for an indefinite period. Record shipments are being made.

The Ruth-Hastings Glass Co, Conshohocken, Pa., specializing in the manufacture of glass tubing, has resumed operations at its local plant after a shutdown for many months It is expected to advance production at an early date, giving employment to an increased working force

Negotiations are said to be under way for the purchase of the plant of the American Plate Glass Co James City, near Kane, Pa., by New York interests, for a consideration of close to $5,000,000 The plant will be developed to maximum capacity by the new owners

CERAMIC—The Central Refractories Co., New Lexington, O, has completed improvements and the installation of additional equipment at its local plant, and purposes to operate at on a capacity basis, giving employment to a full working force. Improvements will also be made at the Orviston, O plant, and maximum output developed at this works

The National Fire Proofing Co., Pittsburgh, Pa, is operating its East Palestine, O, plant at full capacity, and is said to have orders on hand to insure continuance on this basis for an indefinite period. The branch plants at Keasbey and Natco, N. J., are also running full, and it is expected to make extensions in these two plants at an early date for greater output

The Provo Brick & Tile Co, Provo, Utah, is running under a maximum working schedule, giving employment to a normal working force, and will continue on this basis indefinitely The company has plans under consideration for enlargements in the plant, doubling the present rated capacity.

The Edwards Brick Co, Columbia, Mo., manufacturer of brick and tile, is running full, with regular working force, and will continue on this basis for an indefinite period The company has recently installed a quantity of new machinery for greater capacity

The B Mifflin Hood Brick Co, Atlanta, Ga is operating at capacity at its plant at Walden's Ridge, Tenn, for the manufacture of floor and roofing tile A new building is being constructed at the plant for increased production, and will be placed in service at an early date

LEATHER—The Central Leather Co., New York, N Y., has advanced production at its tanneries to about 60 per cent of capacity, as compared with an operating basis of 40 per cent a short time ago It is expected to make a further increase at an early date

The Carr Leather Co, Peabody, Mass., is running at close to normal capacity, devoting practically the entire output to suede leathers A normal working force is being employed

A number of glazed kid plants at Wilmington, Del are curtailing operations and are letting employees go temporarily. The change is said to be due to the lack of export business

The Richard Young Co., Wilmington, Del., is maintaining full operations at its local tannery, specializing in the production of kangaroo and other leathers.

RUBBER—The Howe Rubber Co., New Brunswick, N J, manufacturer of inner tubes for automobile tires, is running at full capacity, giving employment to a regular working force.

The Goodyear Tire & Rubber Co., Akron, O, is running at maximum output on a basis of 1,000,000 tires every 45 days. Plans are under way to enter on a spring production schedule of 40,000 tires a day, a capacity never before attained at the mills.

The Dunlop Tire & Rubber Co., River Rd., Buffalo, N. Y., scheduled to open its local plant on May 1, will devote initial production to heavy pneumatic tires, solid rubber tires and cord tires. A large working force will be employed

The Lee Tire & Rubber Co., Conshohocken, Pa., is maintaining full production at its local mill, giving employment to a normal working quota. Orders on hand are

said to insure this basis of operation for some time to come.

The Firestone Tire & Rubber Co., Akron, O., is arranging to advance production at its plant to a basis of 80,000 tires a day, a record figure in the history of the company

IRON AND STEEL -The Republic Iron & Steel Co., Youngstown O, has blown in its Youngstown-Hanna blast furnace The stack has been idle since November 1920

The Replogle Steel Co., Wharton, N. J, is making ready to blow in the second blast furnace at its local mills. The unit has a rated capacity of 600 tons per day The active furnace, with like capacity, is running full.

The Emporium blast furnace, Emporium Pa., is said to be planning to blow in the stack at an early date The plant has been idle for some time past.

The Woodward Iron Co., Woodward, Ala, is completing repairs and improvements at its second Vanderbilt blast furnace, and plans to blow in the stack at an early date, placing all five furnaces on the producing list.

The Brier Hill Steel Co., Youngstown, O., has work under way on the relining of its Tod blast furnace and plans to blow in the stack as soon as it is ready.

The Youngstown Sheet & Tube Co, Youngstown, O., is increasing production in its open-hearth department, and will run at capacity for an indefinite period

The United States Steel Corp, New York N. Y., is operating its plants in different parts of the country on an average basis of 91 per cent of maximum output, establishing a new high record at a number of the mills

The Valley Mould & Iron Co, Sharpsville, Pa, is operating at all but one of its blast furnaces, giving employment to a large working force.

MISCELLANEOUS The New Jersey Zinc Co., Palmerton, Pa, is increasing production at its plant and adding to the working force A wage advance of 10 per cent in the form of a quarterly bonus to all employees has been made.

The Noble Oil & Gas Co., Burkburnett, Tex. is operating its local gasoline refinery at capacity, developing an output in excess of 1,000,000 gal per month The plant will be continued on this basis for an indefinite period.

Pratt & Lambert Inc, Tonawanda St, Buffalo, N. Y., is maintaining full capacity operations at its local varnish-manufacturing plant, giving employment to a full working force Tentative plans are under consideration for the erection of additions

The International Ultramarine Works, Rossville, S. I., New York, is maintaining regular production at its local plant, with normal working force

The River Raisin Paper Co., Monroe, Mich, is running at capacity, giving employment to a regular working force

New Companies

THE HICKORY BALL CLAY CO., Mayfield, Ky., has been incorporated with a capital of $50,000, to operate a clay mining and refining plant for commercial production The incorporators are G. W. Ligon, A C. Plumlee and W A Ligon, all of Mayfield

THE CELLU-WASTER CO, 78 Paris St, Newark, N. J, has been incorporated with a capital of $50,000, to manufacture celluloid and reclaimed celluloid products composition specialties, etc. The incorporators are Patrick W. Smith, B. Waterbrook and Dean Lawrence

THE ALBERT DAVID CHEMICAL CO, New York, N. Y., care of the United States Corporation Co., 65 Cedar St, representative, has been incorporated under Delaware laws with capital of $300,000, to manufacture chemicals and chemical byproducts.

THE KERR PORTLAND CEMENT CO, Wheeling, W. Va., care of the Capital Trust Co. of Delaware, Dover, Del, representative, has been incorporated under Delaware laws with capital of $3,500,000, to manufacture portland cement The incorporators are S. B Wilson, Wheeling; Alvin M. Keys and J. W. Ferguson, both of Burgettstown, Pa.

THE ALOKA CHEMICAL CO., 5618 Harper St., Chicago, Ill., has been incorporated with a capital of $12,000, to manufacture chemical specialties. The incorporators are Mark L. Day, George L. Williamson and S E. Lambert.

THE INDIANA SANITARY POTTERY CO., Hammond, Ind., has been incorporated with a capital of $100,000, to manufacture sanitary ware The incorporators are Frank S Crumley, Abraham and Jacob C. Newar, and Peter W. Meyn, all of Hammond.

THE CUSTELOID CO., New York, N. Y., care of Samuel Rubin, 120 Broadway, New York, representative, has been incorporated with a capital of $10 000, to manufacture celluloid products The incorporators are J Lefkowitz and D J Cohen

THE DOBBINS-DWYER MFG CORP, New York, N Y, care of R L Armstrong, 50 Church St, New York, representative, has been incorporated with a capital of $200,000, to manufacture chemicals and chemical byproducts The incorporators are C Sullivan and R M Dobbins

THE HILLSBOROGH PETROLEUM & GAS CO, Tampa, Fla, has been incorporated with a capital of $250,000, to manufacture petroleum products S. W Mahaffey is president and general manager, and M L Vincent, secretary and treasurer, both of Tampa

THE DALEY PAPER CO, Bangor, Me. has been incorporated with a capital of $10,000, to manufacture paper products The incorporators are E Desmont Daley and James J. Sullivan, both of Bangor

THE KETTLE CREEK REFINING CO, care of the Corporation Trust Co. of America, du Pont Bldg, Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $600,000, to manufacture refined oil products

OTTO GOETZ, INC, Brooklyn, N. Y, care of C Eichler, 481 Knickerbocker Ave, Brooklyn, representative, has been incorporated with a capital of $200,000 to manufacture glassware and glass products The incorporators are P, J and Otto Goetz.

THE SWITCH PLATE CORP, Norfolk, Va., has been incorporated with a capital of $100,000, to manufacture glass products S W Harris is president, and H R. Walker, secretary, both of Norfolk.

THE HENRY COUNTY OIL CO, Crystal Lake, Ill, has been incorporated with a capital of $25,000, to manufacture petroleum products The incorporators are Edward E. and George E. Grant, and Alfred O Erickson, 511 City Hall, Crystal Lake The last noted represents the company

THE MOUNTAIN STATE GLASS CO, Mannington, W. Va, has been incorporated with a capital of $100,000, to manufacture glass products The incorporators are H D Atha, C L. Prichard and R F Alder, all of Mannington.

THE MONTAGUE CASTINGS CO, Montague, Mich, has been incorporated with a capital of $20,000, to manufacture iron and other metal castings. The incorporators are John O Reed, Whitehall, Mich; Fred J Howden, Muskegon, Mich.; and Charles W. O'Brien, Montague.

THE MILL PRINTING INK CO, Brooklyn, N Y care of Watson, Kristeller & Swift, 68 William St., New York, representative, has been incorporated with a capital of $60,000, to manufacture printing and other inks The incorporators are H D Watson, J C. Williams and F. W. Kristeller.

THE NORTHEASTERN OIL CO, Boston, Mass, has been incorporated with a capital of $100,000, to manufacture oil products. G A Bergfors is president, and William J. Bursaw, Beverly, Mass., treasurer.

THE HEMOLENE CHEMICAL CO, St. Louis, Mo, has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are G L. Kitchen and L. J McKim, both of St. Louis.

THE ALHAMBRA BRICK & TILE CO, Sturgis, Mich, care of Edmund S Hellings, Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $1,150,000, to manufacture brick, tile and other burned clay products The incorporators are Fred P. Leaming, Sturgis; Harry H. Culver, Chicago, Ill.; and Charles Peters, St. Louis, Mo

THE FIBEROID BUTTON & FINISHING CO, INC., Waterbury, Conn., has been incorporated with a capital of $25,000, to manufacture fiber washers, insulating washers and other fiber products. The incorporators are W. D. Munson, Middlebury, Conn.; B. D. Cashman and E. V. Ball, 25 State St., Waterbury. The last noted represents the company.

THE DANVILLE OIL SYNDICATE, INC., 1106 First National Bank Bldg, Danville, Ill., has been incorporated with a capital of $150,000, to manufacture petroleum products. The incorporators are Howard A. Swallow, Robert R. Bookwalter and Samuel E. Phillips.

THE E-X CHEMICAL PRODUCTS CORP., 101 New Jersey Railroad Ave., Newark, N. J., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are P. M. Beach, R. E. Fried and John J. Sloat.

THE DANFORTH-ABBOTT CO., New York, N. Y., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated with a capital of $500,000, under Delaware laws, to manufacture polishes and kindred products. The incorporators are John L. Farrell, Theodore L. Harrison and William F. McDermott, all of New York.

THE NEW HAVEN GRAY IRON WORKS, INC., New Haven, Mich, has been incorporated with a capital of $15,000, to manufacture gray iron and other metal castings. The incorporators are Jay Baldwin, Louis C. Harris and A. J. Bennett, all of New Haven.

THE DIRTENEMK CHEMICAL CO., INC., 118 West Patrick St, Frederick, Md., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts The incorporators are M. Roy Sharrer and Clarence M. Albaugh.

THE UNITED STATES & CANADA PETROLEUM CO, care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del, has been incorporated under Delaware laws with capital of $40,000,000, to manufacture petroleum products.

THE ENTERPRISE GALVANIZING CO., Philadelphia, Pa., is being organized under state laws to manufacture galvanized metal products Application for a state charter will be made on Feb. 27. The company is represented by Clinton O Mayer, 1218 Chestnut St, Philadelphia

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va., May 7 to 9.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O., April 28 to May 4.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting June 20-23 at Wilmington, Del.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Eastman Hotel, Hot Springs, Ark., April 30 and May 1

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923

IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 10 and 11 at the House of the Institution of Civil Engineers, London, S W. 1.

NATIONAL FOREIGN TRADE COUNCIL has postponed its annual conference from April 25, 26 and 27, to May 2, 3 and 4. It will be held in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J, the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chémical Society, joint meeting. May 4—American Chemical Society, regular meeting May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY and IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 New York, March 7, 1923 Number 10

The Evil of the Tax-Free Security

EXPERIENCE of the past few years has made it very clear that the tax-exempt security and the progressive income tax cannot live in peace together. The tax-free bond tends to destroy the graduated feature of the income tax. That the tax rate shall increase with the increase in the size of the individual's income is a principle which has been firmly established in the code of equity of every civilized people, and the man who predicts that the people in this country will tamely submit to the nullification of progressive income taxes is a very blind prophet indeed. To be sure, most students of the problem agree that the federal income tax scale has been pushed to a height which is difficult to justify and that it should be modified as soon as the fiscal exigencies of the Treasury will permit. But income taxation, graduated to very substantial levels, is here to stay, and the warping, distorting effects of the tax-exempt security would probably survive even the most radical revision of the income tax that lies within the realm of possibility.

The opportunity—or rather the compulsion, for it is an opportunity which the rich man must be economically insane to ignore—to invest in tax-exempt bonds has brought about a revolution in the normal investment habits of large owners of capital. Persons who normally could place their funds in public utility or industrial bonds now must ignore such offerings unless, indeed, the utilities or industries chance to be publicly owned. The result has been unfair to private industries in a double sense. Not only are they shut out from their customary market for money but at the same time competing public undertakings are given a subsidy in the form of abnormally cheap money.

The extent to which this country has indulged in tax-exempt securities was recently brought out before the Ways and Means Committee in a striking manner. It was testified that there are between 10 and 15 billions of state and municipal tax-free bonds in existence and a further 3 billions of United States bonds are totally exempt. In addition there are outstanding about 18 billions of United States bonds containing certain exempt privileges for the next 3 years, so that it may be safely said that the total of tax-exempt securities lies between 20 and 30 billions of dollars. Just what proportion of this amount has been spent on developments other than the agencies of production and distribution is not known and is difficult to estimate. But it is evident that with such temptations for public extravagance, our efforts to achieve economy in public affairs are very seriously threatened.

Whatever his views may be regarding the severity of the surtaxes in the present federal income tax, the business man will be wise to regard as a separate issue any proposals for their reduction. The only surtaxes nullified by the tax-exempt securities are those applying to investment or "unearned income." Moreover the nullification of these rates is at the cost of a derangement of the investment market, in misdirected economic effort and, consequently, in waste. The only feasible road back to normalcy is to be rid of the tax-exempt bond.

The Artistic Temperament In the Practice of Chemistry

SOMETIMES the talk over a club table is worth repeating. Five or six men were at luncheon to the accompaniment of speculative discourse. "I hardly think," said one of the number, referring to a leading chemical technologist, "that he succeeded because of any mathematical bent of his mind. The man is primarily an artist and has the real artistic temperament. I don't mean the hysterical emotion of an opera singer; I mean the sense of rightness. He hates waste rather because it indicates the wrong way to produce than because it is economically wrong. His sense of form and color is such that he would have succeeded as a painter, a sculptor or an architect, if the curiosity that makes chemists had not gained possession of him. He abhors a mess of any kind. An inadequate yield produces waste, and waste again is usually a mess, which is contrary to his artistic sense."

This called to mind another eminent chemist whose contributions to pure science are known the world over. He has mathematics available and uses it as a tool, as a short-cut to reach his conclusions, but he does not worship mathematics as his less gifted brethren do. This man, in addition to his major work, practices one of the fine arts as an avocation.

One of the party suggested that all good chemists are born, not made, but he could not get a discussion of his postulate, because it led into the tiresome old dispute as to heredity or environment being of leading weight in influencing a man's career.

Agreement was reached, however, that curiosity, the untiring curiosity of a child, the drive to find out, is a leading requirement of anyone who would devote his life to the application of chemistry. Most of those present insisted that an active and projective imagination is of equal importance. Now this is the equipment of the true artist: the keen imagination that sees things as he is convinced they should be. A defective reaction offends him. His curiosity eggs him on to study it, but his artistic temperament will not let him rest until he has discovered the reaction of his ideal, the way to do the thing as it should be done.

At the conclusion of the discourse the impression prevailed that any chemical engineer who reaches the

heights must be an artist in his work. He may be a master at manipulation, an extraordinary craftsman, but if he lacks the needful imagination, the art of seeing things as they should be, before they are made, he cannot reach the front rank. Chemistry and the fine arts are closely related.

Is Public Education Worth What It Costs?

OFFHAND the average American will answer this question with a strong affirmative, but probably he will reckon without a knowledge of all the facts. The expenditure for education in the United States has been mounting upward by leaps and bounds, as is clearly set forth in the 1922 annual report of the Carnegie Foundation for the Advancement of Teaching. The president of the Foundation, Dr. HENRY C. PRITCHETT, is plainly concerned over the trend in public education; and the astounding figures that he presents make us pause and wonder whether we are on the right track.

The expenditure for primary and secondary schools in the United States—i.e., for grade and high schools, as we call them—has risen from $140,000,000 in 1890 to over $1,000,000,000 in 1920. The enrollment in public or grade schools has risen during the same period from 13,000,000 to 22,000,000—an increase of 70 per cent—while the enrollment in public high schools jumped from 200,000 to over 2,000,000, or an increase of more than 1,000 per cent. The increase in college attendance has been likewise a striking feature, although figures are not given. It appears, however, that while attendance at grade schools has kept pace with the increase in population, that of high schools and colleges has advanced at a rate of growth several times the rate of increase in population. In 10 years the cost of education per capita has increased from $34 in New York State in 1910 to $106.97 in 1920. This is only an example.

It is pleasing to think that so much is done for education in this country and that there is such a widespread interest in the subject. But, as Dr. PRITCHETT says, "it is possible to dissipate enormous sums of money in the name of education which serve neither to equip children with a body of knowledge nor to train their minds, nor to instruct them as to their duties and rights under the government through which the education is furnished." His protest is that with such increasing costs we may soon reach a burden that is too heavy for the respective communities to bear. "In no country in the world," he says, "does so large a proportion of the energy of the teaching profession devote itself to the tedious task of lifting ill-prepared children and youths through courses of study from which they gain little or no good."

Our interest is in technically trained men and in skilled workmen who know how to use their hands and are willing to use their heads. We do not want them to learn to loaf on their jobs at school. We want our technical men not only to have thorough training in physics, chemistry and engineering, but in addition to this we want them to have the consciousness that they are professional men with professional obligations in the community.

We think the signs of the times point to a simpler and less expensive government with compulsory grammar school education. Secondary and higher education should be for those who want it and are competent to achieve it. Others gain no profit from secondary and higher education, although the expense of trying unsuccessfully to train them is indeed becoming a tax that may grow too heavy to meet.

The attitude on the part of business toward education in the United States is disclosed in a recent referendum conducted by the Chamber of Commerce of the United States on the question of a federal Department of Education with a Secretary in the President's Cabinet, and the principle of federal aid to education in the states on the basis of an equal share of the expense. It is significant that the referendum disclosed a strong opposition against both proposals. A third one relating to the enlargement of the present federal Bureau of Education brought out a strong negative vote but not sufficient to commit the Chamber against the proposal. Evidently business in the United States, as represented by the constituent bodies of the National Chamber, has sensed something of the conditions brought out in Dr. PRITCHETT'S report, and feels that we may well pause and take stock of our efforts at education before we go further.

What Causes Variations in Lime?

ELSEWHERE in this issue we publish a note by OLIVER BOWLES of the Bureau of Mines which is suggestive and stimulating. It seems that not so very long ago a woman, Miss SQUIRE, president of the Allwood Lime Co., completed a series of test burnings on different kinds of limestone which led to the isolation of one in particular. This stone on burning yielded a special lime that sold for as high as $200 a ton—a good wholesome dollars-and-cents reason for wondering just what it is about a limestone that affects the lime produced from it.

Of course one very obvious variation is impurity, but apparently that is not the only factor nor yet the significant one. In a given limestone bed there are many strata and the different layers yield widely variant limes. Why? Is the variation a regular and progressive function of the depth? Not at all. It is true that in general the older strata will be denser, and this, of course, will have its effect. But from a geological point of view the various conditions prevailing at the time of sedimentation, such as the density of the medium, the origin of the calcareous material, the time required, etc., all affect the variety of limestone deposited. These conditions may have changed frequently in the deposition of any given bed, so that the strata vary irregularly and may change every few inches.

There is a large school that still adheres to the idea that differences in lime are due to differences in method of burning. This undoubtedly has a distinct effect, but indications have almost reached the point of conclusive proof in showing that it is not the whole story. A careful systematic study of the fundamental properties of burned limes, together with historical data as to their origin, will probably be necessary before a comprehensive answer can be given. Of course these historical data must be specific enough to distinguish between the different limestones in the same quarry. The problem seems to offer not only a wonderful opportunity for constructive research but a fertile field for play of imagination as well. And the solution may conceivably revolutionize some phases of a tremendous industry.

The Vertical Trust In American Industry

THE tendency toward the adoption of the vertical trust by American industry becomes more evident with each passing month. Recent news items from the glass-manufacturing district near Pittsburgh report the purchase by the Ford Motor Co. of the Allegheny Plate Glass Co., with a yearly production of 7,000,000 sq.ft., and the purchase by W. C. DURANT, of Durant Motors, Inc., of the American Plate Glass Co., with 6,000,000 sq.ft. annual production. These are only the latest of a long series of similar items, typified by the Ford control of mines, railroads, blast furnaces, coke ovens, artificial leather factories and, in fact, of almost all the various agencies that go to make the complete motor car or enter into its production in any way.

While the automotive industry provides, perhaps, the most conspicuous examples of this "vertical" type of organization, the tendency is fully as marked in industries which are more strictly chemical and metallurgical. For examples, we might point out the Newport Chemical Works, organized, as its slogan reads, "From coal to dyestuff"; or the Aluminum Company of America, which controls its product from mine to consumer. Numerous other examples of more or less well-developed vertical trust will come quickly to every mind. The tendency is already well founded and is evidently rapidly increasing.

Now, therefore, while this growth is still in its infancy it will be profitable to study it somewhat and ask ourselves what it holds in store for chemical and related industry. Consolidation into larger units seems to be the necessity of the day. Obviously, to change from our customary method of "horizontal" mergers to the "vertical" method will have some effect. It will be well for industry to consider what this will be while the movement is still young, so that the necessary steps can be taken to meet the new kind of competition that will result.

Atomic Speculation

A MASS of evidence—much of it derived quite recently from X-ray studies—indicates that solid solutions are dispersions of atoms (not molecules) in the solvent, and these "stranger atoms" replace their hosts at or very close to the exact position in the normal space lattice of the solvent metal. This replacement or substitution, atom for atom, is accompanied by distortion of the space lattice, more or less extensive, and a correspondingly greater amount of internal energy in the crystal.

DR. WALTER ROSENHAIN, in his recent lecture before the Institute of Metals (presented in digest elsewhere in this issue), develops beautifully several logical deductions from the above discoveries. Undoubtedly none of his hearers but admired the way he argued his conclusions, showing how they corresponded with known metallurgical facts. He was thus enabled to group many of the metals into classes showing combinations of properties, in striking agreement, yet so far having escaped notice.

In the face of this achievement, it is easy to let criticism sleep. Yet we think it will not be captious to point out that it is possible our eminent guest has at one place drawn out the theory a little too fine. To explain the phenomenon of the mushy stage, he notes that the solvent atoms immediately surrounding the stranger will melt with it first because of their distorted positions, to be followed at higher temperatures by the next layers, less and less disturbed from their normal lattice and containing less and less potential energy.

If one agrees that the stranger atoms locate the points where fusion begins, it is hard to see why the distorted lattice should remain disturbed after the cause of the disturbance has been removed, especially since at temperatures near melting the atomic mobility is large and the rigidity of the lattice is low.

Apparently it is necessary to avoid getting too close to the infinitesimal limit—there must be a sort of mass action—else it would be easy arithmetic to figure each atom of solute to influence just a few solvent atoms, in this region the concentration being high enough to melt. This reduces us to the rather absurd position that all the solvent atoms must enter the liquid state as soon as the first one melts.

A more attractive explanation is contained in a recent communication from FRANCIS B. FOLEY. Consider a cooling solution, like carbon steel. When the temperature reaches 1,530 deg. C., the melting point of iron, there is a definite tendency for cubic crystals of pure iron to form. Doubtless such aggregation of iron atoms does take place, but the alloying tendency of carbon is also present, and atoms of carbon assume some position on these elementary crystals, distorting their structure so that everything immediately disrupts and re-enters the liquid state. The liquidus is reached when the atomic attraction of the iron lattice is just sufficient to overcome the kinetic disturbances of high temperature and the distortions caused by diffusion of the correct amount of carbon into the crystal.

On this supposition, at any temperature in the mushy stage there is an interchange of both solvent and solute atoms between the solid and liquid phase, and melting occurs by the entrance of an excessive amount of stranger atoms into a lattice already strained near the breaking point by harboring many guests.

Another point where we would make a suggestion: Dr. ROSENHAIN supposes that diffusion occurs by a stranger atom moving in a short line, pushing ahead a long line of atoms and dragging behind a tail long enough to reach from the grain boundary. This involves what appears to be very large forces. Is it not more reasonable to suppose that only a small group of atoms rotate?

Assume, for instance, that the stranger occupied the face center on a cubic system. The four corresponding atoms of the lattice unit might interchange places in cyclic manner, the action being repeated with new partners as often as necessary for the stranger to find its last resting place. This involves breaking bonds on four atoms only instead of many thousands. The objection that the atoms are keyed against rotation would hold with equal force against movement by translation—if the corner atoms key the face-centered atoms against rotation, the face-centered atoms also key the corner atoms against translation. The most attractive thing about diffusion by rotation of a unit lattice or a part of it is this: The action is extremely local, and occurs within a region where the lattice is already distended by the mere presence of the solute atom.

Accelerated Reactions in Pulsating Gaseous Currents

To the Editor of Chemical & Metallurgical Engineering

SIR:—The article in your issue of Dec. 27 entitled "Accelerated Reactions in Pulsating Gaseous Currents," by J. Deschamps and J. F. Shadgen, and the comments by various correspondents which have appeared in several issues since then have interested me greatly. My interest is largely due to the fact that I have had a practical application of the principles advocated by Deschamps and Shadgen under observation for several years and I should like to call attention to one phase of the subject which I believe has not been brought out by any of your correspondents.

We have here a Gayley dry air blast plant for drying the air supplied to the blast furnaces by refrigeration. In this system air is forced into a chamber by a fan and passed over a nest of pipe coils cooled by means of the circulating refrigerated brine. On these coils the moisture condenses. The air is then led by means of a duct to the suction side of the blowing engines. In one case these engines are of the reciprocating type and the varying demands they make on the air supply as the different engines get into step and fall out of step cause rather strong pulsations of air pressure in the refrigerating chamber. These fluctuations of pressure are of the order of 2 or 3 oz. per square inch and have a frequency of about thirty to sixty per minute.

When I came here several years ago I was struck by the fact that the moisture content of the air leaving the refrigerator was always appreciably below that corresponding to the temperature of saturation. The most satisfactory explanation for this result that I can give is as follows: On entering the refrigerator one immediately notices the fluctuations in air pressure by the somewhat unpleasant sensation on one's ear drums. Then he will notice what seems to be a flickering of the lights in unison with the pulsations of air pressure. Upon closer examination it will be observed that at each rarefaction a fog forms, causing a halo around each light which disappears at each compression. The air has evidently been cooled so that the water vapor is near its point of saturation and since in every pulsation the part of the cycle representing an expansion is accompanied by a drop in temperature some of the vapor condenses to form a fog. Now if in that part of the cycle representing a compression the accompanying rise in temperature causes a complete re-evaporation of this fog, then these pulsations will cause neither a loss, except through friction, nor a gain, except inasmuch as they improve the circulation of the air among the coils as argued by Messrs. Deschamps and Shadgen. But as long ago as 1870 Sir W. Thompson demonstrated that a small drop will evaporate in air containing so much moisture that condensation would take place on a flat surface. (See Chapter XX, Capillarity, in "Theory of Heat," by Clerk Maxwell.) Consequently if any of these small drops in the fog formed during a rarefaction come in contact with any surface, they will immediately flatten out and will not re-evaporate in the compression half of the cycle. The effect of this will be to maintain the absolute humidity below that corresponding to the saturation humidity at the average pressure and temperature of the air. The amount of this condensation is dependent on the amplitude and frequency of the pulsations of pressure. In fact, it would be quite possible to extract a large part of the moisture of the air with only cold water in the pipes by increasing the variations in pressure.

The point I am trying to bring out is that if a certain reaction is influenced by the pressure, then in a varying pressure a lowering of the pressure will not always undo the effect brought about by the raising of the pressure or *vice versa*. In some cases this can be made to be of advantage.

A. E. MUELLER.

Maysville, Wis.

They All Aspire

To the Editor of Chemical & Metallurgical Engineering

SIR:—Apropos your editorial in the issue of *Chem. & Met.* dated Feb. 21, relative to the popularity of the term "engineer," the following was clipped from a recent issue of the New York *Tribune*:

Everybody's One of 'Em

No longer little Micky Hare,
  Whose ways are wild and meek,
Will keep my clothing in repair
  For 50 cents a week.
He now demands a larger sum,
  Which I esteem too dear,
For lately Michael has become
  A Pressing Engineer

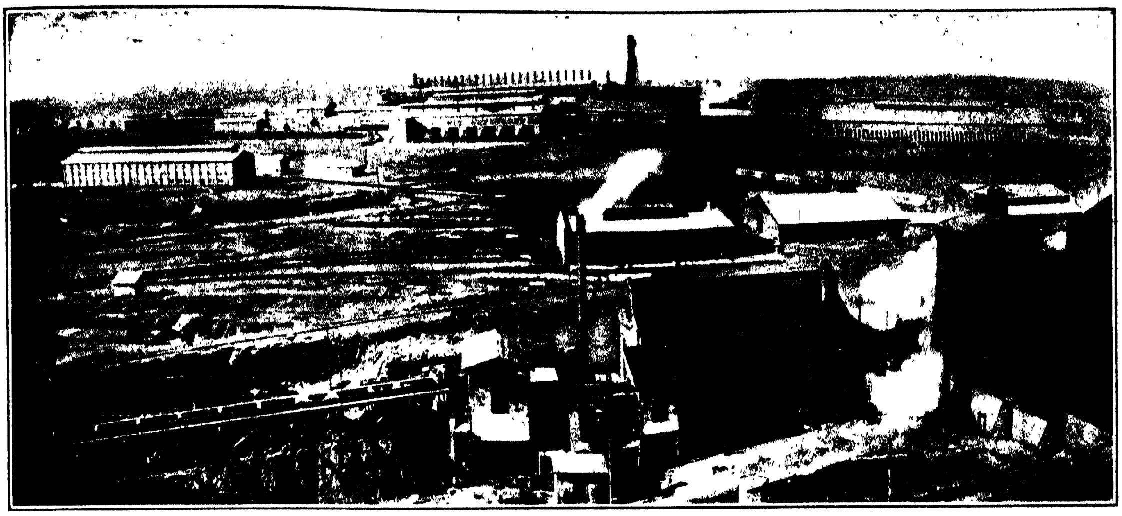
The days when Tonto Dorio
  Would clip and trim my lawn
And make my kitchen garden grow
  For ten a month are gone
He now is making wads of pelt,
  Takes contracts by the year,
And on his billheads styles himself
  A Mowing Engineer.

The lads from Greece who cleaned my shoes
  Once in a cheaper time
Now with a haughty scowl refuse
  My little proffered dime.
One sees them by appointment now,
  They're risen, it appears,
And have become, so they avow,
  Shoe Surface Engineers.

Old 'Rastus Johnson comes no more
  To take the cans away,
Or knocks upon the kitchen door
  To seek his weekly pay.
He's found a means of getting his—
  The dusky profiteer—
His card informs me that he is
  A Garbage Engineer.

It would seem that in the profession of chemistry one also finds those who, though not doing work which can be classed as that of a chemical engineer, have taken over the name at least. I have in mind one man who holds a high position in a large concern. This man is in reality a chemical engineer and performs such work. So disgusted has he become, however, at the tendency of all professions to adopt the term engineer, and in particular the tendency of all chemists to describe themselves as "chemical engineers," that he refuses to allow himself to be so designated, preferring to be known as an "industrial chemist."

New York City. PAUL D. V. MANNING.



PANORAMA OF PLANTS 2 AND 1 OF THE ATLAS PORTLAND CEMENT CO., NORTHAMPTON, PA.

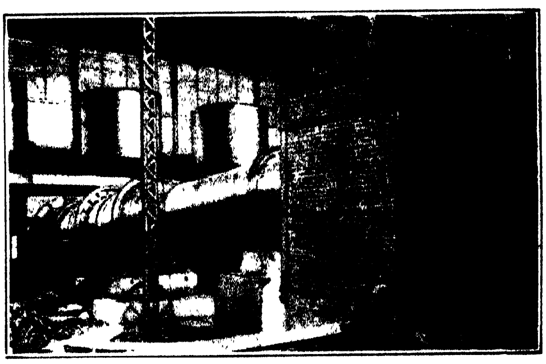
A Pioneer Passes

An Appreciation of the Work of the Late Harry J. Seaman, of the Atlas Portland Cement Co.

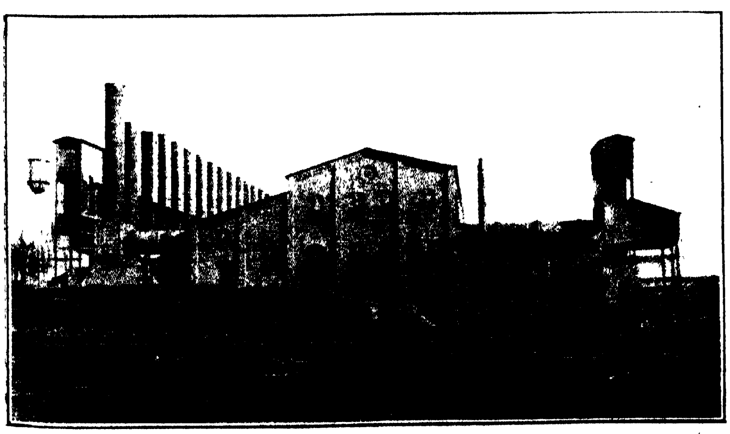
H. J. SEAMAN

IT IS perhaps almost a truism among those who are familiar with technical progress to say that it is seldom dramatic. Certainly as an industry or a process develops, the steps by which it progresses are so gradual, so almost imperceptible, that at times and for long periods it may seem to stand still. Yet if, for some reason, there is occasion to review a long period, the elements of the dramatic appear. Progress has been stupendous and amazing, the imperceptible steps have slowly but surely achieved a revolution. So when the announcement of the death of Harry J. Seaman appeared in the daily press, a host of friends paused in retrospect and realized, many with surprise, that a great leader and pioneer had died. An unfailing courtesy which had endeared him to his colleagues and subordinates, and a most retiring modesty, had militated against a popular appreciation of his excellent work.

He was graduated in chemistry from Lafayette in 1879, and with 13 years of experience in metallurgical work he came in 1892 to be superintendent of the Atlas Portland Cement Co., which was then being organized. During his first years in the cement industry many costly experiments were being made in an attempt to use oil for firing the kilns, and Mr. Seaman, with an associate, an English engineer named Hurry, began a series of experiments on the use of pulverized coal in cement burning. There was something approaching the dramatic in the application of these experimental runs to plant work. A large plant was constructed, using pulverized coal as a fuel, but the plant was also equipped with oil-burning appliances as a precautionary measure and to some extent to throw competitors off the trail. The operation of this plant was carried on for 2 years before many of the competitors realized the secret of its success. A whole industry then followed his lead. In the accompanying photograph of the Northampton plant, it is interesting to note that the brick building in the foreground is the original coal-pulverizing building



EARLY 60-FT. KILN



224-FT. KILN, CAPABLE OF TURNING OUT 1,800 BBL. CEMENT PER DAY

erected in 1894 for the new Atlas cement company plant. The kilns in this plant were relatively small, 6½ ft. in diameter by 60 ft. long. In the background of the same photograph is plant No. 4, erected in 1904, with kilns still 6½ ft. in diameter but 135 ft. long. There followed, step by step, the construction of larger and larger kilns. In 1906 a unit 8 ft. 5 in. in diameter by 135 ft. long; in 1909, 10 ft. in diameter by 224 ft. long, and finally, in 1910, four kilns were constructed 12 ft. in diameter by 233 ft. long. During the 22 years in which Mr. Seaman was at the helm of the Atlas, the company grew from a small industrial plant of seven kilns to the huge organization operating 103 kilns with a combined output of 50,000 bbl. a day. This in 1914 made it the largest cement plant in the world. A severe illness then robbed Mr. Seaman of his energy and for 2 years he had virtually retired from active work. But during the war he was instrumental in the installation of potash-recovery systems to remove the potash from the cement kiln dust and he combined this process with waste-heat boiler installation and a complete elimination of flue dust from the kilns. The combination of these installations was unique and again represented pioneer work.

It is appropriate that we should pause for a momentary appraisal and appreciation. Mr. Seaman gave a high type of service to his company, to the industry and to the public. In its detail of progress, it was seldom dramatic, but as a whole it presents a picture which will serve as an inspiration for many years.

Present Situation in the German Glass Industry

In a recent trade dispatch from Berlin concerning the German glass industry, it is reported that in the table glass branch of the industry deliveries of raw materials have been difficult to obtain. Demand in the home market has decreased, but this decline is thought to be temporary and all the plants are very busy at present with orders on hand. Encouraging reports of the improvement in trade come from the East, Italy, Rumania and German Austria.

The hollow glass industry has experienced considerable difficulty in procuring raw material. In spite of the consequent increase in price of raw material, the finished article has not advanced unreasonably. The recent fall in the value of the mark has revived foreign trade in some measure, but the small orders received will not be sufficient to keep the various plants in operation for any length of time. A further decrease in coal supplies will render it necessary to close many plants entirely.

Specifications for Chemical Lime

The rapid increase in the use of commercial lime as a chemical in recent years has been recognized in technical circles throughout the country. There is no more striking evidence of this than the action of the American Society for Testing Materials in establishing standards for lime for chemical uses. The first of these chemical lime specifications appears in the 1922 Tentative Standards of the A.S.T.M. covering the use of lime in the varnish, paper, textile and silica brick Industry.

Work upon specifications for lime for all its other many chemical uses is now actively in progress by the A.S.T.M. committee C-7 on lime through its sub-committee on chemical lime under the chairmanship of Dr. M. E. Holmes. Other technical societies are co-operating in this work and it is expected that in due time standards of quality for lime will be set up covering all its important chemical uses. This should lead to greater efficiency in lime production and greater economy and quality in the use of lime.

Record Production in 1922 of Fuel Briquets

According to the United States Geological Survey, a record production for fuel briquets was established during 1922, when the total output amounted to 619,425 net tons. In 1920, 398,949 tons were produced.

FUEL BRIQUETS PRODUCED IN THE UNITED STATES IN 1917-1922

Year	Net Tons	Value	Year	Net Tons	Value
1917	406,856	$2,233,888	1920	567,192	$4,623,831
1918	477,235	3,212,793	1921	398,949	3,632,301
1919	295,734	2,301,054	1922	619,425	5,444,926

The deficit in domestic anthracite in the region supplied by the upper Lake docks resulted in a greatly increased production in the Central States. Other districts have also reported an encouraging increase. The same type of binder has been generally used and a similar raw fuel constituent employed in the various plants.

RAW FUELS USED IN MAKING BRIQUETS IN THE UNITED STATES 1919-1922, IN NET TONS

Fuel	1919	1920	1921	1922
Anthracite culm and fine sizes and semi-anthracite	118,595	356,877	190,964	254,563
Semi-bituminous and bituminous slack and coke	*97,387	*125,506	121,925	235,542
Lignite, sub-bituminous coal, and oil gas residue	80,383	89,656	†85,352	†123,339
	296,365	572,039	398,241	613,444

* Includes no coke † Includes no brown lignite

Of the fourteen plants that operated, six used anthracite culm or fines, two semi-anthracite, one a mixture of anthracite fines and bituminous slack, one semi-bituminous slack, one a mixture of bituminous slack and sub-bituminous coal, two carbon residue from the manufacture of oil gas, and one bituminous coal, first subjected to low-temperature carbonization. The total quantity of raw fuel used was 609,186 net tons, of which 42 per cent was anthracite or semi-anthracite, 39 per cent semi-bituminous slack, bituminous slack and coke, and 19 per cent sub-bituminous coal and oil-gas residue.

First Glass Factory in Lithuania Completed

In a recent trade report from Berlin it is stated that the construction of the first glass factory in Lithuania has just been completed at Petrasuoni. The factory is equipped in accordance with the most modern technical requirements and stands in the center of four villages, opposite a high road, not far from the railway, on the Niemen, 5 km. from Kovno. Bottles will be the main product and modern machinery has been installed. Extensive peat fields have been rented 3 km. from the factory and special machinery has been installed for digging peat.

Production of Alcohol in Poland

Of the 2,000 agricultural distilleries existing before the war, 1,420 are at present in operation within the territory of the Polish Republic. The estimated production of the agricultural and industrial distilleries during the present campaign is 1,200,000 hl. of alcohol of 100 deg. The home consumption is placed at 600,000 hl., leaving the same quantity for export.

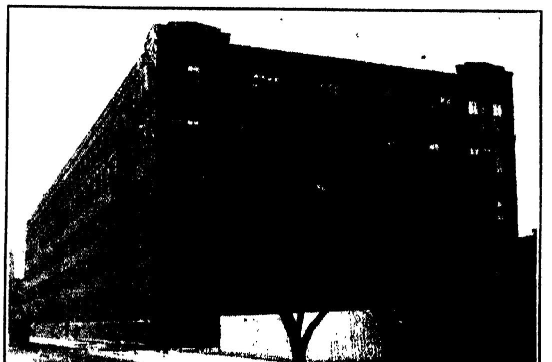
Wall Paper Manufacture In a Model Mill*

Hanging Paper Made on Fourdrinier Machines Is Coated With a Clay Slip, Giving a Surface Upon Which the Design Is Printed With Lake Colors Suspended in an Adhesive Medium

MURAL decoration is a subject which in all probability dates back to the crude effects obtained by primitive man when he varied the monotony of bare walls of his cave by draping them with skins of animals. Later, with the development of textile arts, woven materials were largely used, and from the eleventh to the middle of the eighteenth century the tapestry industry flourished. Cloth painted in imitation of tapestry subsequently became popular and it is but a short step from this to the use of paper as a base. Printing ink and ordinary hand presses were used at first, followed by the process of printing from hand blocks, which is still in use for particularly artistic effects.

About 1839 Potter and Ross, in England, began investigations which resulted in the adaptation of calico-printing machinery to the printing of wall paper. It is to this development that the modern machine-printed wall paper industry owes its origin.

This is a very interesting branch of the paper industry and yet very little technical information is available regarding it. Accordingly the following outline of processes employed by a mill which has many unusual features may be of interest. The mill, which is that of Sears, Roebuck & Co., Chicago, occupies a 5-story building provided with a thirteen-car siding from the tracks of the Baltimore & Ohio Chicago Terminal Railroad. As the mill has a capacity of 30,000,000 rolls of wall paper per year, the need for adequate transportation facilities is evident.



EXTERIOR VIEW OF A MODEL MILL

In the trade, it is customary to refer to paper base upon which the design is printed as hanging paper, while the finished wall paper is termed paper hangings. Several paper mills make hanging paper, which is then sold to other firms more properly referred to as wall paper printers than as wall paper manufacturers. The latter term implies plants in which the whole series of operations is carried out. The Sears, Roebuck & Co., mill is of this type, being a self-contained unit. The paper is made, the colors are prepared and the printing is done all within the establishment.

Waste paper of various kinds—catalog trimmings, office waste, records, overissue newspapers, etc.—is reduced to pulp together with a certain amount of groundwood and sulphite, coloring matter and sizing. The groundwood and sulphite are received in the form of laps, bales or rolls. The pulping operation is begun in pulpers and beaters of the usual type, the mill being equipped with two 2,100-lb. Niagara and one 1,750-lb. Allen beaters. The beater furnish varies according to the type of hanging being made, since it would not be possible to obtain some of the lighter colored effects on stock which might be perfectly satisfactory for a dark shade.

When the stock in the beaters or pulpers has been properly disintegrated it is discharged to concrete stuff chests, which serve to store the pulp until it is fed to the Jordan engines, which complete the pulping operation by separating the cluster of fiber still more. The pulp then passes to a set of stuff chests, which keep it in suspension so as to insure a uniform feed to the paper machine.

For forming the paper, a 132-in. Fourdrinier machine is provided. When running on hangings the full width of the machine is not used, but it is adjusted to give a trimmed sheet 117 in. wide, since this will just make six rolls wall paper width, 19½ in. The main portions of the machine are driven by a steam engine, although some of the accessories are motor operated. The speed is 500 to 550 ft. per minute.

Just before entering the flow box on the machine the pulp passes through two rotary screens to remove any coarse fibers which might be present. It then flows at uniform consistency and at a carefully regulated rate onto the endless 65-mesh Fourdrinier wire. The first part of the machine is given a shaking motion at right angles to the direction of flow so that as the water drains through the screen by gravity and the fibers begin to form a sheet they will not point in the same direction but will interweave to produce a strong well-formed sheet. Removal of water is accelerated near the end of the screen by oscillating suction boxes placed under the screen. In these a vacuum equivalent to several inches of water is maintained by motor-driven Nash Hytor pumps. While the paper is in a fluid condition it is kept from flowing off the sides of the screen by two endless deckle-straps of vulcanized rubber about 2½ in. square in cross-section. These are so mounted that they travel with the screen, and the width of the sheet may be varied by adjusting the distance between them.

After passing the suction boxes, the sheet is passed over a suction couch roll. This roll, together with the breast roll at the head of the machine, forms the support upon which the Fourdrinier wire is stretched. This suction couch roll removes enough of the remaining

*This article is based upon an address delivered before the Chicago Chemists' Club by Herbert A. Hauptli, superintendent of Wall Paper Mills, Sears, Roebuck & Co.

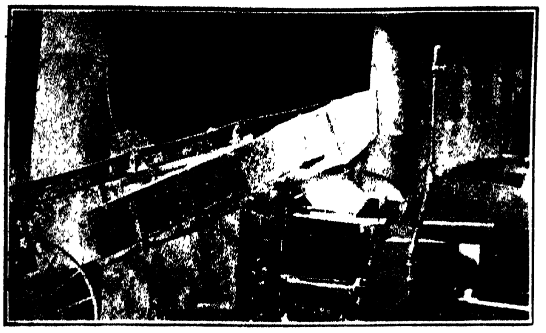


FIG 1—BEATER FOR PREPARING CLAY SLIP

water so that the sheet is sufficiently strong to make the jump to the first press unsupported.

Felt belts carry the sheet during the rest of its journey through a series of press rolls and to the drying cylinders. The drying cylinders are covered with a glass hood which acts as a receiver for all the water vapor as it evaporates from the paper. This vapor is then removed by a powerful fan.

Reels take care of the finished paper as it comes from the machine after passing through a stack of calenders. From the reels it passes through slitters and is rewound on a rewinder as six rolls each 19½ in. wide. These form the wall paper base or hanging. About 45 tons of paper is produced per day.

An unusual feature of the mill is the continued re-use of white water—that is, the water which drains through the Fourdrinier screen carrying with it an appreciable amount of the finer fibers. This is pumped back to storage chests and is ready for use in the beaters and thus circulates continuously through the process. It is of course necessary to add sufficient fresh water to make up for that lost by evaporation in the driers. This amounts to about 75 tons per day. Such re-use of white water is made possible by the fact that no injurious chemicals are used in treating the pulp and consequently there is nothing to accumulate in the water and cause trouble.

China clay forms the base for the coating materials and the colors which are used in printing the designs on the paper. Clay is unloaded from cars on the siding directly to a storage room by means of portable belt conveyors. Another unusual feature is that in one end of the room is a regular Niagara beater in which the clay slip is formed. A charge of clay is transferred from the storage piles to the beater, the required amount of water and glue is added and a uniform slip is rapidly produced. Fig. 1 shows the conveyor in position for charging the beater, with clay storage piles in the background. This beater has replaced a whole battery of agitator tanks and is doing the work more rapidly, more satisfactorily and with less labor and attention. It will handle 5 tons of clay per hour.

For the production of the various colors, portions of aluminum hydrate base are treated in mixing tanks, Fig. 2, with suitable amounts of coal-tar dyes to produce the desired lake or shade. The lake is then filtered through a continuous filter, Fig. 3, and the pulp color is mixed in a kneading and mixing machine with the adhesive vehicle which will hold the color on the paper. Glue, various gums and starch preparations are used in making these pastes. As the pulp colors must often remain in contact with the moist pastes for some time, care must be exercised in choosing dyes and pigments which will not be affected under these conditions. Direct and acid dyes are largely used, although for certain colors inorganic pigments are employed. Some of the special inks do not contain any pulp colors, being composed of paste and such materials as bronze powders or finely ground mica. About 3½ tons of pulp color is produced per day in this department.

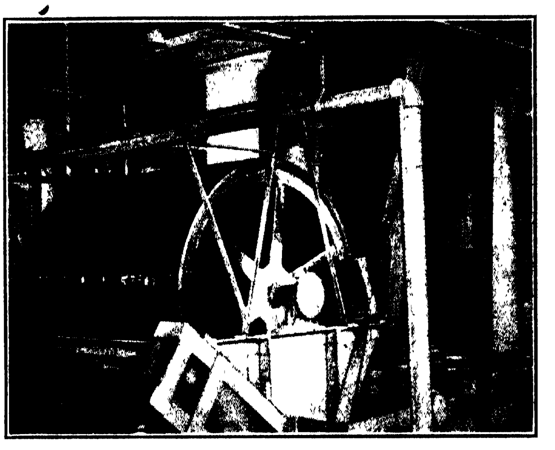

FIG. 3—CONTINUOUS FILTER FOR PULP COLORS

Since the hanging paper does not have the color or texture necessary for the background of the printed design, a coating operation precedes the printing process proper. Coating machines apply a plain ground color to the entire surface of the paper. In some cases the color is simply china clay, or the clay may be made still whiter by precipitating barium sulphate upon it, while in other cases tinted clays are used. These operations are carried out in the tanks shown in Fig. 4. From these the clay is pumped to agitator tanks, which keep the coating in suspension until it is used on the

FIG. 2—COLORED LAKES FORMED IN THESE MIXING TANKS

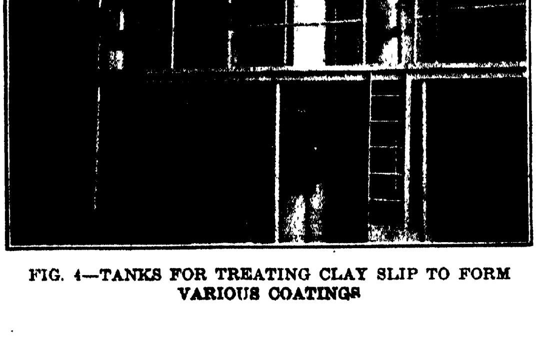

FIG. 4—TANKS FOR TREATING CLAY SLIP TO FORM VARIOUS COATINGS

coating machines. In the latter the paper runs under a roller fed with coating material by an endless belt which dips in a trough containing the clay slip. Brushes working at right angles to the line of motion of the paper distribute the coating evenly. After drying, the paper is ready for the design. The festoon driers used are similar to those which will be described in connection with the printed paper.

In general appearance, the printing machines resemble those used in textile mills. There is a great difference, however, in the printing rolls. For wall paper, these consist of maple rolls with the designs outlined in strips of sheet brass. From the original design prepared by the artist, a series of transfer patterns is made—one for each color. These are then transferred to the wooden rolls and skilled workmen proceed to cut lengths of sheet brass strips, bend them to conform with the curves of the design and then hammer them firmly into the surface of the roll. The brass strips extend about ⅜ in. beyond the surface of the roll. Where solid masses of color are required, the spaces between the strips are filled in with specially prepared felt. When the design has been completed, the surface formed by the projecting strips is ground in a lathe until uniform so that it will print evenly.

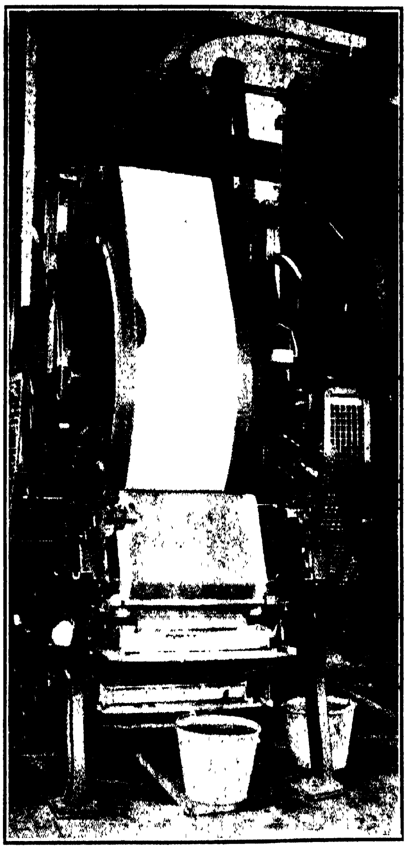

FIG. 5—PRINTING MACHINE

As may be well imagined from the brief outline just given, this work requires skill and unlimited patience. Imperfections in spacing are readily apparent in the finished print, so that the labor involved in the production of, say, a dotted honeycomb design is quite obvious.

All of the rolls required for a given design are mounted on the printing machine. At this mill there are two sets of machines, one for eight-color work, the other for twelve. Each printing roll is supplied with the appropriate color by means of a short felt band which picks up color from another roll revolving in a shallow reservoir or trough containing color. Above this roll is a blade which scrapes excess color from the felt so that just the right amount of color will be transferred to the printing roll. The paper is supported on a rubber blanket during printing in order to insure clear, perfect impressions. These details are evident in Fig. 5, and also in Fig. 6, which shows a battery of printing machines in operation.

FIG. 6—BATTERY OF PRINTING MACHINES IN OPERATION

Paper is fed to the machines from a reel just in front of which is a short belt conveyor. Several yards of paper are carried on this in the form of loose folds, giving sufficient leeway to permit change of rolls without stopping the machine. Passing through the printer, each printing roll contributes its particular color. As the paper emerges bearing the complete design, it is picked up by a series of moving spaced bars and carried in short festoons underneath a duct from which warm dry air issues. With this arrangement the annoyance of spots due to condensation in the hood is entirely eliminated. Fig. 7 is a view along one set of driers, although the individual festoons are not apparent, as they were in motion while the picture was being taken. The lower drier carries paper from the coating machine, while the printed paper is handled on the upper one.

After traveling about 85 ft. the wall paper is thoroughly dry and with some patterns this completes the manufacturing process. In others, however, subdued effects are produced by overprinting the whole design with a sort of screen, usually in white. This is done on a supplementary printing machine followed by another festoon drier. Embossed effects may also be obtained by running the paper through an embossing machine having properly surfaced rollers.

FIG. 7—VIEW ALONG FESTOON DRIERS

Special papers include the oatmeals and varnished tile. The surface of the former consists of colored or tinted stock containing comparatively fine particles of sawdust. In the latter, the design is printed from engraved rollers and the entire surface is coated with a transparent spirit varnish.

Ingenious automatic machines reel up the paper in measured 16-yard lengths, at the same time perforating the selvage edge so that it can be removed easily after the paste has been applied. This feature is fully protected by United States patent and is used only on Sears, Roebuck paper. These double rolls, as 16-yard rolls are known in the trade, are wrapped up in a very neat manner and placed in stock or shipped to the stores at Chicago, Philadelphia, Dallas and Seattle. For delivery, the rolls are packed in paper cartons. As noted previously, the mill has a capacity of about 30,000,000 rolls of wall paper per year.

In spite of the large amount of glue used, the characteristic odor so common in many mills is entirely absent. This is only one indication of the careful chemical control which is maintained by the laboratory to make certain that the proper care is exercised in the handling and treatment of all materials. Similar attention to a multitude of other details has resulted in spotless cleanliness throughout the mill. The paper machine is painted white and no rubbish is allowed to accumulate anywhere. An efficient ventilating system insures comfortable working conditions at all times. Indeed, at every point indications of efficient and understanding management are in evidence.

Bureau of Mines Works on Explosives

Much experimental work on explosives is at present under way at the experimental station of the Bureau of Mines, at Pittsburgh, Pa. One of the most important researches is for the determination of fundamental data on the solubility, hygroscopicity, melting point and decomposition temperatures of compounds used in explosives. This information leads to the development of methods of purification and separation of materials and thereby makes the handling of explosives less hazardous. The solubility of TNT in eleven solvents has been determined and the data are ready for publication.

Small-scale tests of ammonium nitrate are being made to determine its explosibility by means of boosters only. The tests will be made at normal temperature with the ammonium nitrate at normal density and with such a degree of confinement as is found suitable from preliminary tests. The compression of small lead blocks will be used as the criterion of explosibility. The use of the following explosives as boosters is contemplated: Picric acid, tetryl, TNT, TNA, amatol 80/20, high-grade ammonium dynamite, blasting gelatine and 40 per cent ammonia dynamite. This work is being done in co-operation with the National Research Council, which will direct further work on the problem.

One of the important problems in metal mining, tunneling or quarrying is the most economical method of bringing down the ore or rock. The two factors having great influence in determining this are drilling and blasting costs. In considering the efficiency of the explosive used, the diameter of cartridge has always been supposed to play an important part. However, the attention of the Bureau of Mines has been called to the lack of definite data on the effect of cartridge diameter on the strength and sensitiveness of high explosives. This information is especially valuable to the user of explosives, as it assists him to determine what diameter of borehole is most economical. Accordingly the bureau, in co-operation with the Institute of Makers of Explosives, has conducted a series of tests to show the effect of cartridge diameter on the strength and sensitiveness of certain high explosives. The results of these tests are given in Serial 2436, by Spencer P. Howell, explosives engineer, and J. E. Crawshaw, explosives testing engineer, which may be obtained from the Bureau of Mines, Washington, D. C.

Information regarding additions, removals and changes in the permissible list of explosives from March 15 to Dec. 31, 1922, is given in Serial 2430, by S. P. Howell, explosives engineer, which has just been issued by the Bureau of Mines. The list supplements that contained in Technical Paper 307, issued in March, 1922.

Increase in Newsprint Production in Canada

In a study made by the Canadian Pacific Railway, figures have been compiled which permit a comparison of the newsprint situation in Canada in 1922 with previous years. During the first 10 months of last year production reached 896,840 tons, an increase of 237,249 tons over the same period for 1921. As the American market depends upon Canada for approximately one-third its annual consumption, the bulk of the dominion's output comes to the United States. More than 900,000 tons was exported last year, but it has been estimated that Canada and the United States will together use 13 per cent more newsprint this year than in 1920.

Increased advertising on this continent will also result in a greater consumption of newsprint and if the demand from Oriental and European markets continues, the coming year will in all probability show the largest newsprint production in the history of the industry in Canada. A comparison of figures for a 10-year period indicates the extraordinary development of the Canadian newsprint mills. The total output in 1913 amounted to 350,000 tons. In 1921 it had advanced to 805,114 tons, an increase of 130 per cent. During the 10-year period, 1912-22, it has been estimated, there was an increase of 300 per cent in the production of newsprint.

Sugar Refining in Bulgaria

Bulgaria has five large, well-equipped beet-sugar factories with a potential producing capacity of 50,000 metric tons of refined sugar annually, according to a recent report to the Commerce Department. National pre-war sugar consumption in Bulgaria, which ranged around 35,000 tons annually, has now declined to about 25,000 tons. Thousands of refugees have migrated into the country from Macedonia and east Thrace and the population has increased by about 500,000 over pre-war figures despite a loss of 8.5 per cent in territory. Were the factories operating at full capacity, the country would already be on an exporting basis. The director of a large sugar factory located at Sofia stated that his plant will not run at more than 20 per cent capacity this season. The beets cannot be obtained; farmers are holding out for higher prices for the raw beets and display a tendency to turn from beet raising to the culture of more remunerative crops such as tobacco. Sugar producers are of the opinion that Bulgarian domestic production during the present campaign will amount to about 15,000 tons of refined sugar; thus a surplus of 10,000 tons remains to be purchased abroad.

Stafford Wood-Carbonization Process

An Apparently Successful Attempt to Use Wood Scrap From Lumber Mills Outlined—All of the Valuable Byproduct Recovered

AFTER hundreds of unsuccessful attempts have been made to utilize small waste wood in the carbonization and wood-distillation industries, Prof. O. F. Stafford, a University of Oregon man, has perfected a process that is commercially successful. A superior grade of charcoal as well as the usual wood-distillation products can be obtained from mill waste under his process. So it is reported by *Science Service*.

Professor Stafford first demonstrated his process scientifically on the University of Oregon campus. He and the firm of engineers behind him have now succeeded, after several years' work, in demonstrating it as a practical commercial process. Two wood-distillation plants on the Atlantic coast, one of them controlled by a big corporation, placed every resource at Professor Stafford's disposal, and the success of the process was completely demonstrated.

By the new process a fine grade of charcoal can be obtained as well as the usual byproducts of carbonization, acetic acid, acetone and methanol, basic in the manufacture of such articles as dyes, paints, varnishes, celluloid, smokeless powder and artificial leather.

Economical Advantage of the Process

Cord and slab wood have been the accepted material used in making charcoal and its byproducts. As small waste wood is materially cheaper than either slab or cord wood, the desirability of utilizing it in carbonization operations has long been recognized. Eight hundred applications have been made at various times at the Patent Office by those who thought they had hit upon a process of carbonizating small waste wood on a commercial scale. The failure of these efforts, until the Stafford process was proved successful, has been due, in general, to heavy costs of installing and maintaining the complicated mechanical appliances required.

In 1920, after experimental demonstrations at Cambridge, Mass., work was continued in a plant of 200 cords daily capacity at Kingsport, Tenn., which had originally been erected by the National Research Council during the war for chemical experimentation.

The commonly accepted practice of carbonization is to place cord or slab wood in large oven retorts made of steel plate. Fires in the furnaces beneath are started. Vapor outlets from the oven are provided, these outlets leading to condensers for the recovery of the liquid products of the distillation. The charcoal is withdrawn after the wood has been carbonized.

The Stafford Carbonizing Chamber

The retort used in the Stafford method is a cylinder, 32 ft. high and 9 ft. in diameter. The cylinder is set vertically and the appliances are such that the wood to be carbonized is fed continuously into the top, while charcoal is withdrawn continuously from the bottom. A remarkable feature of the process is that no heat is applied to the cylinder after the process once is started, the carbonization of the wood being spontaneous under the conditions which the invention maintains.

In previous processes the principal difficulty encountered in the use of small waste wood has been that of transmitting heat to the interior of a mass of finely divided woody material in the retort. Such a mass is a poor conductor of heat. Only the portions of it in contact with the hot walls of the retort can in any reasonable time reach a carbonizing temperature. The numerous attempts to handle such material have had to do principally with overcoming this difficulty.

Formerly the wood used in carbonization work has always contained moisture. But Professor Stafford experimented with perfectly dry wood. He found that when the dry wood is heated under his process to the temperature at which the charring begins the carbonization went along to completion without further application of heat from outside sources. In other words, the process is exothermic.

Cost of Installation and Upkeep Low

The cost of installing a plant under the new plan is considerably less than that of building an oven retort plant of equivalent capacity. It has other advantages, among which are low depreciation and low labor and fuel costs as compared with other systems.

It has not yet been demonstrated whether the charcoal made under the Stafford process can be used in the iron industry. The charcoal produced from small waste wood would have to be briquetted for direct use in a blast surface.

In the working out of the Stafford process in the Pacific Northwest, Douglas fir would be the most available species of wood. It occupies an intermediate position between the hardwoods and the soft or resinous wood, such as the Southern long leaf pine. Hardwoods give a high yield of wood alcohol and acetic acid, while the Southern pine gives low yields of alcohol and acid but a high yield of turpentine oils and resins.

Magnesia as Polishing Agent

In a paper entitled "Polishing Aluminum and its Alloys for Metallographic Study," by E. H. Dix, Jr., appearing in *Chem. & Met.* for Dec. 20, 1922 (p. 1217) and presented before the February meeting of the Institute of Metals division of the A.I.M.E., it was recommended that magnesia be used as the final polishing medium. Dr. Walter Rosenhain, who originated its use, says that it is necessary for the magnesia to be kept clean and perfectly dry. It is best to try some "heavy magnesia" from several makers, rather than buying through a broker, and then place repeat orders direct with the source of a sample which will satisfactorily polish copper, gold or any soft metal. It is possible for the individual to calcine the carbonate, but not necessary to go to this trouble. Likewise, it is impossible to levigate the product after its formation.

Polishing disks must be kept vigorously clean. Each day they must be scrubbed with a hand brush and a copious amount of freshly distilled water, continuing the process for some time after the cloth appears quite clean. If the disk is not used constantly, it should be flooded with distilled water daily, and kept constantly wet.

The great advantage of magnesia as a final polisher is that a trace of it does not produce complicating reactions in the etching medium. The disadvantage is the ease with which it transforms into gritty particles of carbonate.

Second Institute of Metals Lecture

A Digest of Walter Rosenhain's Address Upon Atomic Arrangement in Solid Solutions, and How This Will Affect Such Phenomena as Melting Range, Hardness, Diffusion and Intermetallic Compounds

HAVING been asked to give an address on some theoretical aspect of metallurgy, Dr. Rosenhain chose to propose a new theory on the nature of solid solutions. Even though there is no quantitative proof of each step of its development, there is a body of experimental evidence in support of the main theory, and logical conclusions drawn from it are in striking accord with well-known facts. While solid solutions are by no means confined to alloys, they have been studied most extensively by metallurgists; consequently it appeared best to confine attention to intermetallic solid solutions.

Solidification of Solid Solutions

The term "solid solution" is paradoxical to the uninitiated, involving a contradiction of terms. What it connotes is approximately "a crystalline body formed either from a liquid solution or from an intimate mixture of solids, or from both, which retains in the solid state an admixture of the two substances (solvent and solute) as intimate as that which exists in a liquid solution." Equilibrium diagrams of many binary alloy systems show areas where solid solutions are stable—theoretically it seems that complete insolubility is impossible. From typical diagrams, the lecturer reviewed the well-known facts shown on Fig. 1 that a liquid of composition x (e.g., 75 per cent A, 25 per cent B), upon cooling will commence solidifying when the temperature reaches c, but the solid separating is of a composition shown by d on the solidus curve. As the solid is rich in B, it impoverishes the liquid in that element, thus requiring a further cooling before more of it will freeze. If cooling be at a very slow rate, the demands of equilibrium will be met, and the solidified portion also gives up part of its excess of B to its surroundings as it cools. Thus at any temperature during the mushy range the composition of the liquid is represented by a point e on curve L and that of the solid by the corresponding point f on curve S. Finally the last trace of liquid (rich in A) solidifies, and its excess of A will diffuse into the solid, which finally cools as a homogeneous solution of composition g (75 per cent A, 25 per cent B). The same mechanism is followed during solidification of alloys of the type shown in Fig. 2, having only a limited mutual solubility in the solid.

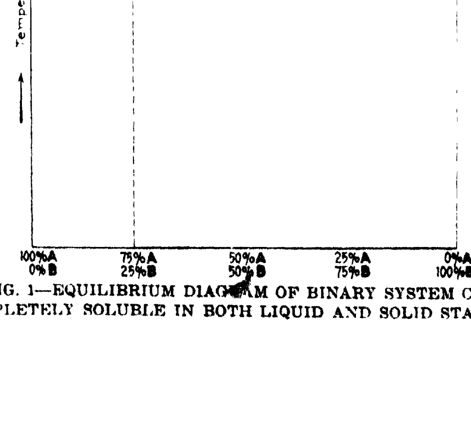

FIG. 1—EQUILIBRIUM DIAGRAM OF BINARY SYSTEM COMPLETELY SOLUBLE IN BOTH LIQUID AND SOLID STATE

Consideration of Fig. 2 indicates that the temperature of melting falls with increasing concentration of solute in the solid solution—that is to say, less energy needs be imparted to a solid alloy to disrupt the atoms sufficiently to transform them into the liquid state. If it be granted that this family of alloys requires a fixed total of energy to induce the mobility of the liquid state, it follows that a store of energy must be held in the crystals of solid solution—that is, the material is "self-strained" with potentially disruptive energy. The limit of solubility in the solid would therefore be determined by the maximum amount of such energy which could be stored in the internal structure of the crystal. The latter conclusion is also reached by elementary thermodynamical considerations even though it is demanded by this theory that a solid solution must occur because it constitutes an atomic arrangement which contains the least amount of stored energy. Solid solutions will continue to form with increasing amounts of solute, until a composition is reached where the energy content of the more highly saturated solid solution would be greater than that inherent to a duplex structure. This implies that increasing concentration of the solid solution brings with it an increasing storage of internal energy until the limit is reached.

Energy Stored in Strained Crystals

How can this energy be stored within the crystals? Here is where the X-ray diffraction patterns give the greatest help.

Readers of *Chem. & Met.* will remember the recent articles by Bain[1] and Jeffries and Archer[2] on this method of investigation. For the sake of continuity it need only be said that if a beam of monochromatic X-Rays be projected through an aggregate of fine crystals, it will be diffracted in a definite series of directions. The diffracted rays, falling on a photographic film, will develop a series of lines or bands whose mutual spacing will depend upon the geometry of the internal structure of the crystal and the distances of the atoms, each to each.

[1] "Studies of Crystal Structure With X-Rays," vol. 25, p. 657 (Oct. 5, 1921).

[2] "Crystalline Structure of Metals," vol. 24, p. 771 (May 4, 1921).

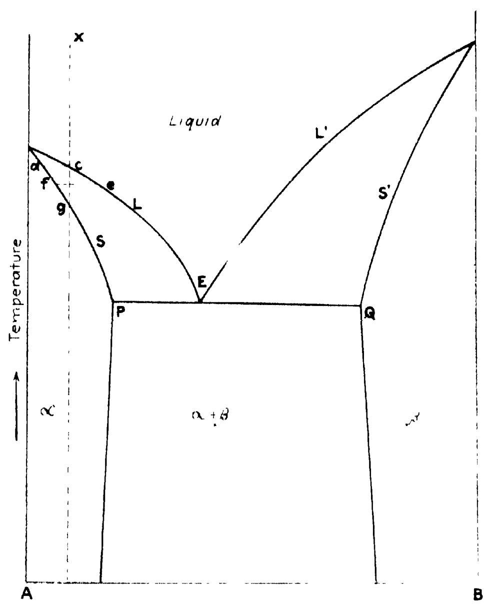

FIG. 2—EQUILIBRIUM DIAGRAM OF BINARY SYSTEM PARTIALLY SOLUBLE IN SOLID

Such studies have revealed the fact that most metals crystallize in relatively simple cubic lattices of varying dimensions. More complex lattices are possessed by brittle metals like zinc, bismuth and antimony, by the compound Fe_3C (cementite), and are to be anticipated in intermetallic compounds.

Essential Structure of Metallic Crystal

We must think, then, of a metallic crystal as built of atoms fixed upon an imaginary framework. The atoms move about their equilibrium position by thermal agitation, but the average distance atom to atom is definitely governed by the forces exerted by its surroundings and which hold it to its mean position in the space lattice. Heating the metal increases the thermal agitation and expands the lattice; when this expansion is carried beyond a certain limiting amount it seems to break the interatomic linkage, and the crystal melts. If the lattice is extended by mechanical means, the new phase formed is Beilby's amorphous metal.

It should furthermore be remembered that it is probable that the atom is a complex structure in itself consisting of a nucleus and an outer system of electrons. It occupies and dominates completely the space determined by the radius to the outer electron shell; and the dimensions of the space lattice are such that the atom volumes so defined almost or quite touch one another. (That is to say, there is no insterstitial space comparable in dimensions with the space occupied by any single atom.) Still the outer electrons or their orbits must be deflected not only by mutual interactions with their neighbors, but also by the application of external stress. Whatever, therefore, tends to change the space lattice also distorts the atoms or at least deranges their outer electrons.

Pure metals, we are assured, possess lattices of great regularity, but solid solutions must be more complex, since they contain many "stranger" atoms (solvent) among those of the host (solute). It is known that such solutions are still crystalline; for instance, alpha brass readily forms twins.[2] X-ray analysis of a solid solution shows also a well-defined space lattice, ordinarily differing only slightly in dimensions from that of the solvent metal.[3]

Do the stranger atoms replace their hosts in their regular positions, or do they find their way into voids? The latter possibility is unlikely, except in very special cases, because there is small room left in a close-packed lattice, and insertion of a stranger atom would distort the lattice beyond the limits of endurance, and second it would demand that solubility be inversely proportional to atomic volumes—a condition which experiment shows does not exist. The alternative supposition—which might be called a "substitution" theory—has been verified by X-ray work in Dr. Rosenhain's laboratory by Messrs. Owen and Preston [and in this country by Dr. Bain]. It also leads to a general view of the atomic structure of solids which explains a wide range of known facts, and should ultimately lead to quantitative verification and even predictions.

Stranger Atoms Substituted for Hosts

Substitution of a stranger atom for an atom of solvent in the space lattice must profoundly affect the entire lattice in that vicinity. Fig. 3 shows the simplest case of the arrangement of atoms along any principal plane in a cubic lattice. Now, replace the center atom with another, Fig. 4. Suppose further that the natural space lattice of the latter, when pure, is larger in

[3] "Nature of Solid Solutions," by Edgar C. Bain, *Chem. & Met.*, vol. 28, p. 21 (Jan. 3, 1923). "Cored Crystals and Metallic Compounds," by Edgar C. Bain, *Chem. & Met.*, vol. 28, p. 63 (Jan. 10, 1923).

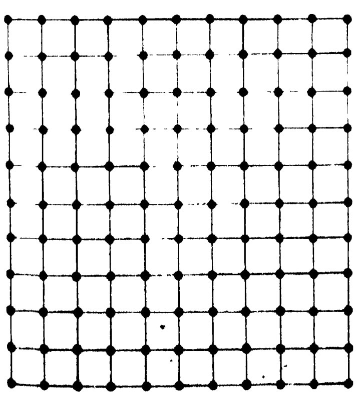

Fig. 3—Spacing of atoms on principal plane of cubic lattice

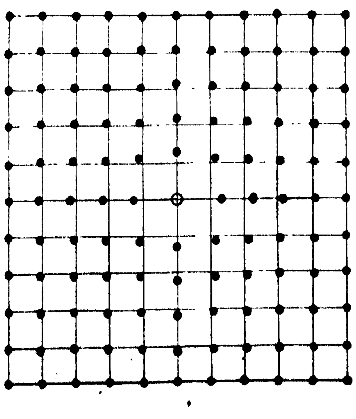

Fig. 4—Distortion in ductile lattice due to large stranger atom

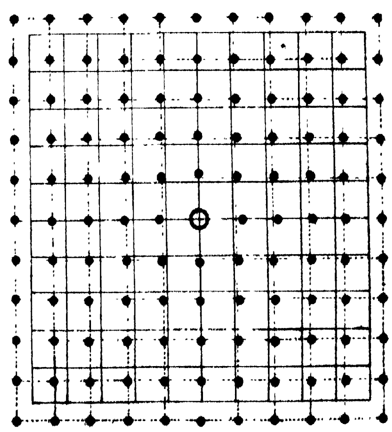

Fig. 5—Distortion in stiff lattice due to large stranger atom

dimension. This would probably mean that the forces between solute atom and the surroundings would be less than those between solvent atoms themselves, and several layers of the latter would shift outward an ever-decreasing amount to balance this lessened attraction. It is apparent that a considerable amount of material is affected. For instance, assume a cube corner to be the center of a disturbance reaching five atoms deep; then a concentration of only one atom in 8,000 would be sufficient to affect the entire mass, bringing about not only a series of local intense distortions but also a slight general expansion of the entire lattice. The relative amount of local and general distortion evidently depends upon the character of the solvent metal itself—a "stiff" lattice might act about as shown in Fig. 5. The first case might be likened to some peas scattered about between the layers of a pile of rubber sheets; the second, to pebbles between tin plates.

It might be argued that the same effect would be

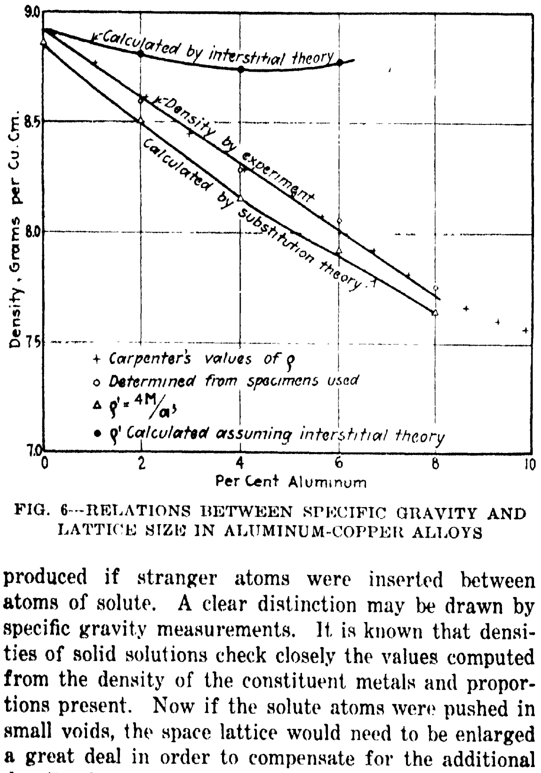

FIG. 6—RELATIONS BETWEEN SPECIFIC GRAVITY AND LATTICE SIZE IN ALUMINUM-COPPER ALLOYS

produced if stranger atoms were inserted between atoms of solute. A clear distinction may be drawn by specific gravity measurements. It is known that densities of solid solutions check closely the values computed from the density of the constituent metals and proportions present. Now if the solute atoms were pushed in small voids, the space lattice would need to be enlarged a great deal in order to compensate for the additional density due to the interpolated solute atoms. If the substitution theory is correct, however, the average dimension of the space lattice would remain practically unchanged. At Dr. Rosenhain's suggestion, Messrs. Owen and Preston studied the copper-aluminum system from this standpoint (Fig. 6) and found the space lattice to correspond very closely to that required by the substitution theory,[4] and widely at variance to that required by assuming the insertion of atoms.

Limit of Solubility

Many interesting inferences can now be drawn, bearing in mind this picture of the atomic arrangement.

First, as to the limit of solid solubility. Evidently, "similar" atoms will enter into each other's space lattice with the minimum of distortion, and the mutual solubility will be large before unstable conditions are reached. The difficulty is to establish a criterion of "similarity." Crystal form and atomic dimensions are naturally of great importance—a metal crystallizing in the cubic and another in the hexagonal system would not be expected to form a continuous series of solid solutions. On the other hand, copper and nickel both form face-centered cubic arrangements with dimensions 3.60 and 3.54 Angstrom units respectively. It is not surprising to find them build an equilibrium diagram like Fig. 1.

Hardening Effect

Second, hardness or the resistance to plastic deformation will be largely affected by the lattice distortion in solid solutions.[5] When a metallic crystal is loaded, it first deforms in an elastic manner until its limit is reached, after which slip occurs and layers of the crystal slide over one another. Such sliding will be easiest in a perfectly regular lattice; the layers of atoms lying on the two sides of such a slip plane may be regarded as two smooth surfaces sliding over each other. Any distortion of the lattice will act as a roughening of this surface, will interfere with slip, and thus harden the metal.[6]

Here are two measurable properties—viz., limit of solid solubility and hardening—which appear to depend upon disturbance of the lattice. Theoretically, the greater the range of solid solutions formed the less should be the hardening effect of the added metal per atom added. What are the actual relationships observed?

To quote only the well-known solutions of copper, the specific hardening effect ranks in the following manner, from least to greatest: Ni, Mn, Zn, Al, Sn. The limit of solid solubility for the respective alloys is 100 per cent, 100, 36, 14, 6.7.

Mechanism of Melting Over a Range

Other even more typical properties of solid solutions may be explained from the standpoint of a distorted space lattice—namely, the occurrences during solidification (or their reverse during melting) summarized in Figs. 1 or 2.

First, consider a crystal of pure metal as it is heated. Increasing thermal agitation of the atoms merely expands the lattice. Thus, Westgren has measured the lattices of iron at various temperatures, and finds they agree with values calculated from the thermal expansion of a bar. As already argued, this expansion cannot exceed a certain value without the appearance of a new phase (an allotropic transformation occurs or the metal melts); and the important point is that all parts of the lattice reach this breakdown at the same temperature. Pure metal melts at one uniform temperature. (It is also significant that refractory metals have, in general, low coefficients of expansion.)

However, a solid solution such as α of Fig. 2 contains many regions where the lattice is locally distended. On heating such a crystal, the locally deformed regions around stranger atoms will reach the limit of lattice-extension first, and melting will begin there and at a temperature at which the bulk of the lattice is still stable. We have partial melting and a liquid appears whose content of solute is higher than the average of the whole crystal. As the temperature rises, further

[4] Bain in this country has verified this fact for several other series of solid solutions. See footnote 8.

[5] "Hardness of Solid Solutions," by W. Rosenhain; *Proc. Royal Soc. London*, A, vol. 99, p. 192; *Chem. & Met.*, vol. 25, p. 243 (Aug. 10, 1921).

[6] "Slip Interference Theory of Hardening," by Zay Jeffries and R. S. Archer, *Chem. & Met.*, vol. 24, p. 1057 (June 15, 1921).

regions of less distorted lattice will melt, diluting the liquid solution, and finally the mushy range is passed and the whole crystal has melted. This will occur at less than the temperature required by pure solvent because the entire lattice is deformed and reaches its limiting extension after a smaller amount of thermal expansion.

On the basis of the substitution theory, the solidus (line S of Figs. 1 and 2), or beginning of melting, depends upon the maximum local extension in the lattice caused by stranger atoms, while the liquidus (line L), or end of melting, depends essentially upon the general extension of the lattice. If local distortion is large and general extension small, the solidus should have a steeper slope than the liquidus, and will be steeper the lower the solid solubility of the stranger atoms. This is generally confirmed. Long ranges of solid solutions give narrow mushy ranges; low solubilities are associated with nearly vertical solidus lines. It may also be inferred that slight local distortions but the general extensions of Fig. 5 are more likely to occur in the rigid lattices of harder and stronger metals of high melting points. This connects strength, hardness, high melting point and ability to form long ranges of solid solutions (e.g., Fe, Ni, Co, Cr, Cu, Ag, Au). On the other hand, soft, low melting metals (Pb, Sn, Cd,) approach the wholly eutectiferous type of diagrams.

While the above argument has been based on expansions of the lattice by stranger atoms, it may be applied *mutatis mutandis* if the solvent lattice is compressed. Then the melting point of the alloy should be higher than that of pure metal (Fig. 1). For instance, alloying nickel (2.50 A.u.) to copper (2.54 A.u.) will compress the lattice of the latter and raise the melting point. The equilibrium diagram shows that even near the copper end of the series the portions first to solidify have a higher nickel content than the liquid from which they form. The silver-palladium system is another striking confirmation of the above facts.

Diffusion

Although the equilibrium diagrams (Figs. 1 and 2) show that the solidified alloys x should have a homogeneous structure, it always occurs that equalization between the first solidified parts and the last remaining mother liquor is never attained during cooling. A cast alloy always shows "cored" crystals. This apparent duplex structure may be obliterated, however, and replaced by the uniform appearance characteristic of pure metal by a suitable annealing far below the melting point.

Bearing in mind that this is done without anything like recrystallization of the alloy,[1] we may ask, By what mechanism does this redistribution of solute atoms occur? Since a space lattice is approximately filled by its constituent atoms, can it open up to allow passage for migrating atoms?

Dr. Rosenhain thinks this may be explained by the phenomenon of intercrystalline slip. As temperature rises, the force necessary to produce slip decreases rapidly. Furthermore, it requires less force to slip a single crystal than an aggregate, where each is supported on all sides by its neighbors. He believes, therefore, that intense local forces set up in the immediate neighborhood of stranger atoms will cause slight slips, probably of only a few atom-diameters distance, rather than the 2,000 or more caused by plastic deformation, and probably only a row or single line of atoms move, rather than a whole layer. If the distribution of the stranger atoms is not uniform, there will be a tendency to slip in a direction leading toward the region of low concentration. Slips of one step at a time, taking place at intervals in the various principal planes of the lattice, will be sufficient to account completely for diffusion—it is obviously possible by a suitable number of successive slips of this nature to carry a solute atom from any one position in the lattice to any other.

Under these conditions, what happens to the atom at the end of the row when slip occurs? It probably passes into the more or less non-crystalline or amorphous layer present at the boundary, while at the other end of the row room is made for the entry of an atom passing into the lattice from the intercrystalline layer. Other considerations lead us to suppose that an interchange of matter constantly occurs at high temperatures between crystals and their boundary layers.

Dr. Rosenhain observed that to test these assumptions about diffusion will be difficult. It would be expected that the atoms which distort the lattice most would cause the most of this extremely local slipping and diffuse fastest. However, we have no experimental data on rates of diffusion. In a qualitative way, however, the extremely sluggish diffusion in copper-nickel alloys has been noted, and in this we have seen that the lattice distortion is very slight. Carbon also diffuses in gamma-iron very rapidly, although its solubility is relatively low. On the other hand, phosphorus diffuses very slowly in iron, its solubility is low, and it has a pronounced hardening effect—i.e., distorts the lattice materially.

Intermetallic Compounds

It is only a step from solid solutions to intermetallic compounds. If the latter be defined as homogeneous crystalline alloys between two metals in such a ratio as to conform to the law of multiple proportions, it would be impossible to distinguish them from solid solutions. Intermetallic compounds, however, have definite characteristics, and are located on the equilibrium diagrams in special ways. Likewise, a definite X-ray spectrum has been found for the compound $CuAl_2$—it is very complex and quite different from either pure copper or aluminum. Doubtless in it, like in some salts which have been studied, the copper and aluminum each builds up its own special lattice, and the two interpenetrate in some way which results in low symmetry.

Since the "substitution" theory of the constitution of solid solutions calls for but a single lattice—that of the solvent metal—here at once is the distinguishing criterion between solutions and compounds. The complex lattice of intermetallic compounds reflects their most striking property—their hardness and brittleness—and explains it in no way in which a consideration of the properties of their ductile constituents would suggest.

Can such complex lattices as intermetallic compounds go into solid solution as such—i.e., in molecular association? It seems obvious that it is impossible. A molecule of $CuAl_2$ is altogether too large to find room upon the space lattice of aluminum. Furthermore, if it could, it would then exhibit its typical X-ray spectrum; and this has not been discovered even in a 96:4 Al:Cu alloy. It follows that the compound does not exist until

[1]Small boundary changes occur during first cooling of the alloy, and mark out areas ordinarily independent of the dendritic structure.

it comes into existence as a separate crystalline phase—it must dissociate to go into solution.

On the other hand, it appears possible for an intermetallic compound *AB* to dissolve metal *A*, by replacing certain of the atoms *B* on its lattice by new *A* atoms, or *vice versa*. Undoubtedly in such cases interatomic bonds play a great part, and it would not be well to speculate until more facts are at hand.

Hardening Theory

There remains one most important consideration—the variation of solid solubility with temperature. That such changes are of the greatest importance to the hardening phenomena has only been recently recognized.

Dr. Rosenhain thinks that the thermal expansion of the two metals concerned should be decisive. Assume a solvent *A* containing a solute *B*, a smaller atom but having a greater rate of expansion than *A*. Then the two should become increasingly similar and more soluble with increasing temperature. However, other factors undoubtedly have influence. It does not seem wholly justifiable to suppose that the thermal expansion of isolated atoms of *B* would be the same as a crystal of *B*. Again, increasing temperature probably changes the atom in other ways than in merely increasing its lattice spacing. Its interatomic bonds, its mobility, its volume may be appreciably changed. Certainly such changes occur in some metals abruptly and profoundly at allotropic transformations. A change in "stiffness" of the solvent lattice with changing temperature is also a factor, since it affects the energy content of the solid solution for a given concentration of solute. It is apparent, therefore, that here again is a matter which must be investigated from many angles before it can be reduced to a quantitative equation.

In conclusion, the lecturer pointed out that a study of atomic lattices and their distortions by stranger atoms would be the first step toward a quantitative metallurgy—where the hardness, limit of solid solubility, rate of diffusion, melting range and brittleness could be computed. In this way, the X-ray may draw a key map to what is now an unchartable wilderness of facts.

Wood Distillation Products in 1921 and 1922

In *Chem. & Met.* for Dec. 27, 1922, there was published a preliminary report of the Bureau of Census on the production of wood distillation products in 1921. In checking over these figures, the Secretary of the National Wood Chemical Association of Bradford, Pa., discovered that the Census Bureau had made an error in reporting the crude methanol production, which according to the estimate of the association was at least 3,000,000 gal. higher than it should be and entirely out of line with the production of acetate of lime. The other figures appear to have been reported more accurately.

The attention of the Census Bureau was called to this apparent discrepancy and that department immediately reviewed the report of the manufacturers of wood-distillation production and the detailed statistics of production for 1921. The revised figures are given in the following table for those products which were incorrectly reported in the previous article.

The Census Bureau's report points out that the output of acetate of lime was relatively small due to the fact that, as some of the manufacturers explained, there was no market for this product and it was found to be much cheaper to use the crude liquor rather than manufacture it in acetate of lime.

	1921	1919	1914
Products, total value	$9,258,500	*$32,625 300	*$10,529,800
Methanol:			
Crude, gal.	3,964,400	9,104,000	9 602,400
For sale—			
Gallons	3,289,300	6,980,700	7,197,000
Value	$1,110,600	$5,593,500	$1,605,900
Made and consumed, gal	675,100	2,123,300	2,405,400
Refined, gallons	2,831,700	7,391,000	6,465,000
For sale—			
Gallons	2,715,300	6,984,700	6,235,100
Value	$1,924,400	$8,381,900	$2,709,400
Made and consumed, gal	116,400	406,300	229,900

For sale—			
Pounds	55,448,900	153,910,000	163,522,000
Value	$737,000	$2,682,200	$2,138,900
Made and consumed, lb.	5,867,400	15,046,000	2,563,000

* Includes byproducts from other industries to the amount of $79,991

1922 Output Doubles

According to a more recent report of the Bureau of the Census, the production of acetate of lime and methanol almost doubled in 1922 as compared with 1921. The total output of firms which produced over 97 per cent of the total acetate of lime in 1921 amounted to 119,911,000 lb., while the methanol production was reported to be 6,687,845 gal. in 1922. The following table shows the monthly production figures as reported by firms with a daily capacity of 4,500 cords (or pro-rated to that capacity in months where some reports were lacking). These were taken from the "Survey of Current Business," published by the Department of Commerce:

	Production	
Months, 1922—	Acetate of Lime, Lb.	Methanol, Gal
January	8,330,000	468,818
February	7,993,000	457,656
March	9,660,000	534,812
April	7,390,000	416,112
May	7,064,000	404,847
June	7,495,000	441,149
July	8,718,000	475,376
August	9,253,000	508,644
September	9,537,000	537,803
October	12,217,000	664,933
November	15,440,000	853,687
December	16,814,000	942,008
Total	119,911,000	6,687,845

Trend of World Production and Consumption of Sugar

Cuba's ability in 1922 to distribute both a record crop and a record carryover can be attributed mainly to a record consumption in the United States and to a European crop that fell far short of the consumption needs of that continent. Cuba exported more than 4,000,000 tons to the United States, approximately 850,000 tons of which (in terms of raw sugar) went to Europe after refining. Altogether, Europe was supplied with 1,700,000 tons toward her deficit of 2,300,000 tons, most of the remainder coming from Java. Approximately 3,000,000 tons of Cuban sugar remained in this country and, combined with the production of the United States and its possessions, supplied the record American consumption of nearly 5,500,000 tons (raw sugar).

Another 4,000,000-ton crop from Cuba is predicted for 1923. Encouraging reports also come from Java and a greatly increased production in Europe is expected. It is estimated, however, that various decreases elsewhere, in the United States in particular, will result in a crop only 125,000 tons greater than last year, which must supply the world consumption of sugar, calculated as 350,000 tons more than in 1922 and 725,000 tons larger than the total production.

An Untrodden Field in Lime Research

An Introduction to the Work Which Must Be Done on the Relation of Lime to Its Limestone Source

BY OLIVER BOWLES
Mineral Technologist, U. S. Bureau of Mines

WIDE research has been conducted in factory and laboratory to determine the physical and chemical properties of lime in their relation to utilization for various purposes. It is now generally recognized that limes differ greatly in their physical properties and chemical activities, such as plasticity, rate of slaking, or rate of settling as milk of lime; but it is not so generally known that these variations often bear no relation to the chemical composition of the original limestone. Limestones of identical composition may, under the same burning conditions, give limes that vary greatly in character. A definite relationship undoubtedly exists between the character of the lime and the physical properties of the parent limestone, but little serious effort has yet been made to correlate them.

THE PIONEER WOMAN

In attributing honor where honor is due it is a noteworthy fact that to a woman must be given credit for the only important practical work that has yet been accomplished in this line of investigation. Miss Mary E. Squire, president of the Allwood Lime Co., Manitowoc, Wis., spent 4 years of investigational work, and finally identified and isolated a particular limestone bed from which is manufactured a lime that commands a price as high as $200 a ton, because it fulfills the most stringent requirements of lime for processes of extreme refinement. Possibly other work of a like nature has been done, but if so it has received little publicity.

The importance of the problem has been brought to the attention of the Bureau of Mines from two other sources, one a lime producer and one a consumer. A prominent lime manufacturer is sufficiently aroused to the significance of the relation between finished lime and the physical properties of limestone that he has expressed a willingness to engage the services of a geological chemist to make a detailed microscopic study of the various formations in his quarry, together with a study of the limes produced. A specialist employed by one of the largest consumers of lime in the United States has written to the Bureau of Mines requesting information on this same subject. Such faint glimmerings betoken the approaching dawn of an active inquiry.

What are the controlling factors—the nature of the original organisms that provided the shells from which the stone was formed; the origin, whether chemically precipitated or fragmental; the degree of cementation or recrystallization; the grain size, grain shape or some other characteristic?

The problem undoubtedly has a direct bearing on quarry processes and on lime utilization, fields in which the Bureau of Mines is enlarging its activities; but so much remains to be done that pioneer work of varying character could be profitably undertaken by several agencies. The field is open; who will supplement our present meager information?

Published by permission of the Director of the Bureau of Mines.

Refined Tar for Coating Cast-Iron Pipe and Fittings*

Discussion of Properties of Tar and Methods of Application to Obtain Satisfactory Coatings of Foundry Products

BY S. R. CHURCH
Technical Adviser, The Barrett Co., New York City

TEN years ago I first gave some attention to the question whether or not there ought to be a specification for a refined tar product for coating cast-iron pipe and fittings. I found that at practically all the foundries crude coal tar was being used. The method of coating varied somewhat, but was usually developed by experience and not marked by close control. I came to the conclusion that the coating could probably be improved by: (1) Closer temerature control of both castings and bath; (2) adoption of some method for testing the consistency of the coating from time to time and keeping it uniform; (3) specifications for the coating that would insure reasonably uniform consistency and freedom from excess water. It did not seem to me at that time that the last-named requirement was of greater importance than the two others.

The tars first used for coating pipe were horizontal gas-works coal tars. In the early days of gas making fireclay retorts were used and the first important change in the character of coal tar occurred when fireclay was replaced by silica retorts. With the latter, higher heats were employed and tar was produced of very high viscosity and high free carbon content.

WATER-GAS TARS LESS DESIRABLE

The newer types of tar—coke-oven, vertical-retort and water-gas—are thinner and of lower free carbon content than the horizontal gas-works tars. Undoubtedly the best coating is not obtained when very thin tar is used. Crude water-gas tar or crude vertical-retort tar makes a very poor coating, lacking body. To obtain a coating having the consistency and covering power of a medium gas-works coal tar, most of the tars now available must be modified by distillation, or reduced to the proper consistency. Either coal-tar or water-gas tar may be reduced to any desired consistency, but it is doubtful whether water-gas tar should be used for pipe coating, as its resistance to chemical attack and its life under conditions of service have not been well established.

What happens when a hot casting is dipped in tar? The object of the process is to obtain a thin but complete coating that will dry in a short time, adhere strongly to the pipe, be resistant to abrasion and finally protect the metal from corrosion. If crude tar is used, the heat is sufficient to drive off enough of the more volatile oils so that the remaining film or coating is pitch. If pitch is used to start with, either higher temperatures must be employed or a thicker coating will result. I do not believe there is any merit in a thicker coating *per se*; on the other hand, a very thin tar may produce a coating so thin as to be non-protective and unduly brittle. I am inclined to the opinion that what is needed is a refined—distilled—tar with reasonable limits as to viscosity and free carbon. The viscosity limits should be specified at an elevated temperature, say 100 deg. C., approaching that of the bath.

Evaporation by Compression

Description of the Process Now in Operation in Several Important Industrial Plants in Europe, Where It Has Proved a Valuable Factor in Heat Economy—Also a Close Study of the Heat Consumption Usually Calculated in the Sugar Industry

BY PROF. DR. WILHELM GENSECKE

By the courtesy of Dr. Frank Mueller, who was associated with Dr. Gensecke in the operation of the experimental plant described.

A GREAT DEAL has recently been written concerning the possibilities of applying steam compression in evaporation, so the principles of the process are undoubtedly known in technical circles. It is important to note that the purpose and function of the compressor are not to generate the heat required for the evaporation, but to raise a sufficient quantity of heat to a higher temperature level; therefore, it is aptly called the "heat pump."

The operation of multiple-effect evaporators is an example, familiar to everyone, of how a quantity of heat introduced into the process can be re-utilized.

A comparison of the thermal economy of multiple-effect evaporation and evaporation by compression must be based on the assumption that the energy necessary for the evaporation by compression has to be generated by steam power, every horsepower involving a definite steam consumption depending on the thermal efficiency of the power plant. On this basis the multiple arrangement is theoretically the better one. The exchange of a certain amount of heat in a surface apparatus presupposes (given a known coefficient of heat and a known heating surface) a certain drop of temperature, which theoretically is the same, regardless of the evaporation process used. Assuming the selected apparatus to be "heat tight," and ignoring any losses by radiation; assuming further that the required heat transfer demands a temperature drop of, say, 10 deg. C., it is not difficult to calculate what amount of evaporation 1 kg. of steam can produce. Only the total temperature drop available for the process need be known. This temperature drop is determined on the one hand by the temperature of the saturated steam of the boiler, and on the other hand by the temperature of condensation, which in its turn is determined by the cooling water of the condenser connected with the last evaporator. If the boiler pressure is 16 atmospheres absolute and the temperature of the saturated steam at that pressure is 200 deg. C., the vacuum of the condenser 92.5 per cent and the temperature of condensation at this vacuum 40 deg. C., the whole available temperature drop is 160 deg. C. and a sixteen-fold evaporation is obtained with 10 deg. C. temperature drop in each evaporator; that is to say, 16 kg. of water can be evaporated in the evaporation plant by means of 1 kg. steam. The plant works with a sixteen-fold effect, and consequently has sixteen evaporator stages.

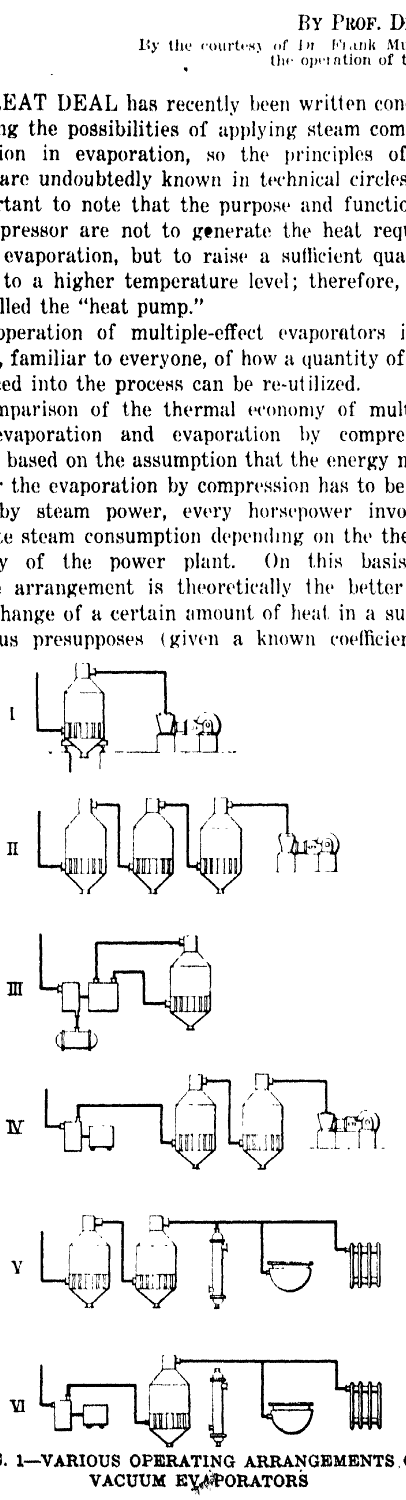

FIG. 1—VARIOUS OPERATING ARRANGEMENTS OF VACUUM EVAPORATORS

The relation thus obtained is a good approximation. In a more accurate examination of this relationship, one must take into account the dependence of the heat content on the temperature.

OPERATION OF COMPRESSION PLANT

How does a compression evaporation plant function under the same conditions? The heating surfaces of all sixteen stages function at the same temperature. They may be imagined as being united in one large heating body. The temperature drop of 10 deg. C. is created by the heat pump, and the amount of energy required is then the same as that required for the running of the compressor. If the compressor and also the driving engine could be run without any losses, 1 kg. of steam in the driving engine would transmit 1 kg. of steam to the compressor, provided a temperature drop of 10 deg. C. (the same as is available for the compressor) were available for the steam of the driving engine. Actually, however, the same drop is available for the driving engine as that which is available for the multiple-effect evaporator—viz., 160 deg. C. Consequently, the result would be the same as with the multiple-effect evaporator—that is, a sixteen-fold evaporation. This relation also is an approximation, as the energy produced by the adiabatic expansion over a certain temperature drop is not exactly equal to the energy requirement of adiabatic compression at the same temperature drop.

As is well known, saturated steam becomes wet when

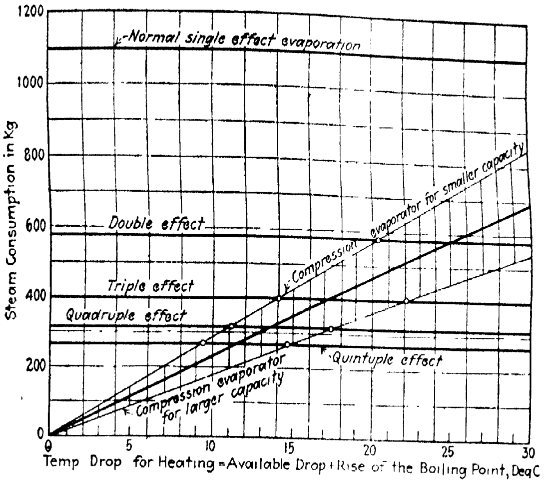

FIG. 2—THERMAL EFFICIENCY OF VARIOUS VACUUM EVAPORATORS

expanded, and superheated when compressed. Consequently, the energy gained during expansion is somewhat less than the energy required for compression, assuming the steam to be saturated at the beginning in both cases.

These are conditions which would govern systems operating without loss. Under actual conditions, it must be remembered that compressors suitable for evaporation operate with an efficiency of 65 per cent, and the same is the case with the driving engine. By multiplying the efficiencies, a resulting efficiency of 0.42 is obtained—that is to say, the compression evaporation plant allows an efficiency of 42 per cent of that of a multiple-effect evaporator. The objection could be raised that in the case of compression evaporation, the heat value of the compressor losses becomes available for the evaporation process. This, however, is inconsiderable in practice, as this work loss of the machine is covered by a thermal efficiency which in most cases is less than 20 per cent.

As far as is known, multiple-effect evaporators with sixteen stages have never been constructed. However, seven or eight stages are sufficient to equalize compression evaporation with multiple-effect evaporators as far as thermal efficiency is concerned. At the same time it must be remembered that evaporation is assumed to be accomplished by a temperature drop of 10 deg. C., and this brings us into fields of operation which seem perfectly feasible. It may be mentioned at this point that evaporators of six stages have often been constructed for the sugar industry.

The number of stages in multiple-effect evaporation is limited by practical considerations. The first stages would have to be operated under heavy pressure. This would make the plant much more expensive and more difficult to operate. In practice, therefore, the number of stages seldom exceeds three.

The considerations mentioned above hold true only for an evaporation process which is independent of other operations.

Usual Operating Arrangements

If one should limit oneself to the above considerations alone, he would arrive at an unfair conclusion, because in modern heat practice a new basis for calculation is created by the coupling of thermal processes. Such a coupling is usually made possible in one of the following ways:

a. Combination of energy-producing system and evaporation process. The back pressure of the engine is used for heating the evaporation plant.

b. Combination of evaporation process and heating process. The vapors of the last evaporating unit are used for boiling and heating purposes, etc.

c. Simultaneous application of methods *a* and *b*. The boiler steam flows successively through the engine, the evaporator, and heating and boiling plant.

The possibilities of these methods of operation are shown in Fig. 1. Plans I to III refer to independent evaporation processes; plan I shows the normal single-effect evaporator; II is an example of a multiple-effect evaporator; III is a compression evaporator with a steam-driven compressor. Plan IV shows a scheme for the utilization of exhaust steam from the engine for evaporation purposes. Plan V shows the utilization of the vapors for heating purposes. Plan VI illustrates the most perfect case of the utilization of heat, thermal coupling of engine, evaporator and heating plant.

In comparing independent evaporation processes, Fig. 2 may be referred to, the calculations from which it is obtained being based on average operating conditions. The high steam consumption of the single- and multiple-effect systems is noticeable. If a comparison is to be made with the compression evaporator, it must be borne in mind that the quantity of steam needed for the compression evaporator is very nearly proportional to the temperature drop that the compressor has to overcome. The manner of calculating the quantity of steam necessary is shown in Table I. The figures in the table obtain for a temperature rise in the compressor of 19.6 deg. C. The steam consumption varies within rather wide limits according to the efficiency of compressor and driving turbine.

Table I shows that the drop in temperature is of decisive importance when judging the economy of the heating process. This varies within very wide limits in the event that increased concentration causes a considerable rise in the boiling point. This point will be considered later.

TABLE I—CONSUMPTION OF ENERGY AND STEAM FOR COMPRESSION EVAPORATOR*

	Larger Plant	Smallet Plan
Efficiency of steam turbine, per cent	0 65	0 45

Consequently, live steam consumption for the evaporation plant, kg. per hr.	**495**	**262**	**182**
Equivalent quantity of low-pressure steam, kg. per hr.	**565**	**300**	**206**

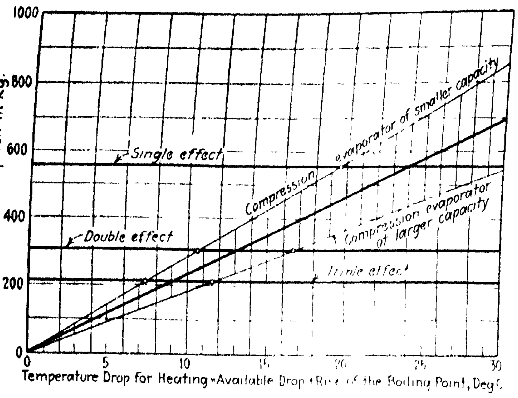

FIG. 3—COMPARISON OF VACUUM AND COMPRESSION EVAPORATORS

If it is possible to operate with a small drop in temperature, evaporation by compression may be far superior in heat efficiency to the five-stage multiple-effect evaporator; on the other hand, a rise of 20 to 30 deg. C. in the boiling point puts the efficiency on a parity with that obtained by double-effect evaporation.

As mentioned above, the evaporator plant is often heated with the exhaust steam of the engine. Thus, a new basis on which to consider the heat economy is created, and the following question is thereby raised: How can the steam consumption for the generation of energy and the heat required for the evaporation be separated in this case? This can be ascertained by subtracting from the total steam consumption of the combined plant that amount of steam consumption corresponding to the capacity of the condensing turbine. The remainder represents the steam consumption of the evaporator. An example is shown in Table II. It must be remembered in this case that the heat content of superheated live steam is not identical with that of saturated steam of low pressure. If, in spite of this, the two quantities that constitute the total required steam are equalized, the heat equivalent of the generated energy as well as the loss of heat due to radiation are fully covered. The conclusion to be derived from this example is that for the given steam conditions the heat required for the evaporation is reduced to one-half of that required with a system operating independently, provided the number of stages are the same. Fig. 3 shows the application of this deduction as a basis of comparison with compression evaporation. If, for instance, a temperature drop of 24 deg. C. is necessary, the compression evaporator equals the single-effect evaporator in efficiency, and furthermore it can be seen that even under more favorable conditions—i.e., the necessary temperature drop—favorable efficiency of compression evaporation can be maintained by arranging two or three evaporators in a series.

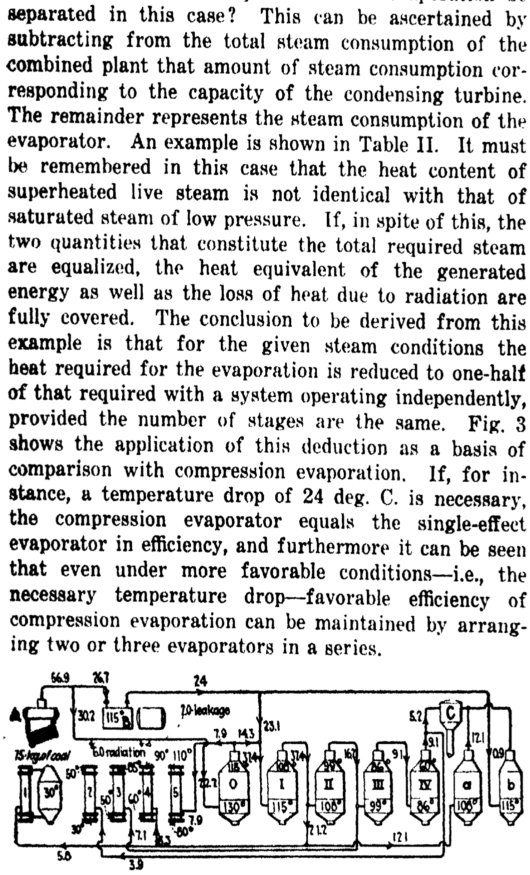

FIG 4—HEAT DISTRIBUTION IN PLANT FOR EVAPORATION OF BEET SUGAR SOLUTION

A—Boiler. B—Engine. 1—Calorizators for diffusion. C—Condenser. 2-5—Heaters for thin liquor. I-IV—Evaporators. a, b—Secondary evaporators. O—Preliminary evaporator.

Considering now the conditions of evaporation where the exhaust steam of the evaporator is used for heating purposes, one must start from the viewpoint that the steam necessary for heating purposes is independent of the construction of the evaporation and power plants. If all the vapors of the evaporators can be used, an improvement of economy is inconceivable. No saving of heat can be obtained by compression evaporation. As an example of an installation where, by a double-thermal coupling, a perfect heat economy is attained, the manufacture of raw sugar may be mentioned, and it may be of interest to analyze such an installation in respect to heat economy, using as a basis figures obtained in practical operation.

Heat Economy in the Sugar Industry

We may assume that the principles of the manufacture of raw sugar are known and therefore need mention only those points which are of importance to heat economy.

The total heat consumption is divided into three separate parts. The first part is required for the production of the thin sugar liquor as well as for the preparation of the same for evaporation. The second part is necessary for the evaporation of the thin liquor, in which operation large quantities of water must be evaporated and in which large quantities of heat are consequently necessary. The last part is essential to generate the mechanical energy in the engines necessary for the manufacturing process.

For the production and preparation of the thin liquor, the beet shavings must first be leached. The juice must then be heated and brought to the saturation point, and finally to the boiling point, the same temperature that prevails in the evaporator. It is customary in the sugar industry to express the necessary quantity of heat in terms of the kilograms of steam necessary for 100 kg. of beets. The figures given in Table III have been established by practical experience, and show the heat consumption for the entire operation.

TABLE III—STEAM CONSUMPTION FOR THE TOTAL PRE-HEATING FIGURED ON 100 KG. BEETS

	Kg.
Leaching of the beets	5.6
Pre-heating of the raw beet juice	11.0
Saturation of the thin liquor and heating up to boiling point	11.2

The evaporation process is divided into two stages: A primary evaporation whereby the greatest part of the water in the thin liquor is removed in multiple-effect evaporators, and a secondary step which is effected with a greater temperature drop in a single-effect evaporator under vacuum. The quantity of water that must be evaporated in this case is not very large. However, the quantity of steam necessary for its evaporation is considerable because, for practical reasons, single-effect evaporators must be chosen.

The steam consumption for the generation of mechanical energy can be calculated if the quantity of energy necessary is known. The latter is given as between 1.2 and 1.5 hp. per hour for 100 kg. of beet shavings. The generation of energy was formerly decentralized to quite an extent. Nowadays a fairly effective centralization is sought for and obtained by using electrical transfer of energy. To make a comparative analysis, losses by radiation and leakage must be considered.

The various heat-absorbing plants are coupled to-

gether thermally in a practical way. The mechanical energy is thereby generated throughout in engines using back pressure, and the total exhaust steam is introduced into the evaporators. By this method the heat consumption necessary for the generation of energy is reduced to a very small quantity. This quantity represents the heat equivalent of the energy generated, so that, not taking into consideration the radiation losses of the engines and the leakage losses, the generation of energy is produced with an efficiency of 100 per cent.

By coupling the evaporator and the diffusion and warming plants, an additional advantage is obtained—viz., that for the primary heating plant only that heat quantity need be considered which is lost in the condenser of the last evaporator. The heat distribution in a modern plant can be seen from Fig. 4, which shows that of the 56.9 kg. of steam which is necessary for 100 kg. of beet shavings, only 2.7 kg. is absorbed for the generation of energy and only 5.2 kg. for the primary evaporator, in which the greatest exchange of heat takes place. Of the remainder, 13 kg. is used for the secondary evaporator and 28 kg. is necessary for diffusion and heating purposes. Radiation and leakage losses require 8 kg. of steam. These figures were established in the operation of an Austrian sugar factory. Corresponding figures of a German factory, which are shown in Table IV, confirm the reliability and correctness of these figures.

Considerations Affecting Steam Consumption

When endeavoring to ascertain whether and to what extent a reduction of the steam consumption is possible and practicable, the following considerations must be a guide. The heat requirement for diffusion and preliminary heating, neglecting the theoretical possibility of utilizing the hot distillate from the evaporator, must be considered as unavoidable, as well as the heat necessary for covering the losses caused by radiation and leakage. If for technical reasons boiling under vacuum in a single effect system is resorted to, it is necessary to generate this additional heat quantity in the boiler, as the heat of the vapors is consumed in the condenser. It is true, however, that the heat necessary for preheater No. 2 could be covered by its heat of evaporation, so that the quantity of steam could be reduced from 13 to 13 — 3.9 = 9.1 kg. Correspondingly, the exhaust heat of the vapors would naturally be increased from 5.2 to 5.2 + 3.9 = 9.1 kg.

The lower level of the obtainable steam consumption, taking into account the above assumptions, would be attained when this loss of the exhaust heat of 9.1 kg. is eliminated. The steam consumption for 100 kg. of beets would be 47.8 kg. The elimination of the heat loss of the condenser can be effected by two methods:

a. Increase in the number of the preliminary boilers arranged in series. In practice, never more than two preliminary boilers have been used.

b. Reduction of the steam consumption for the generation of mechanical energy, which should be tried by centralization and application of higher pressures and temperatures, whereby a larger amount of steam is made available for the preliminary boilers.

By the total elimination of the condenser losses of the evaporation plant, which is a practical possibility, the most favorable operation is obtained. A proposal to operate the evaporation plant with vapor compression would be of no advantage when the generation of mechanical energy is brought about by means of steam power. In case electrical energy can be generated by means of water power, a reduction of the operating costs would be possible only when the price of heat from electrical energy is less than that of coal, multiplied by the efficiency of the boiler. However, there is probably no locality where this is the case, even with very favorable rates for electricity. Even if such were possible, the advantages would be only slight.

Drying Beet Shavings

If, therefore, it is desired to give further consideration to the utilization of vapor compression, the possibility of covering the unavoidable heat consumption of diffusion, preheating and boiling by heat sources which are independent of the manufacture of sugar must be investigated. Such a possibility arises if a plant for the drying of the shavings is run in conjunction with the sugar factory. As such a drying plant is to be found in most modern factories, its possibilities are worthy of consideration.

The value of the dried shavings is so great that devices for the drying of the shavings taken from the diffusion batteries have been quite generally installed, although the heat necessary for the drying is considerable, as the following figures show.

Seven kilograms of dried shavings is obtained from 100 kg. of beets. The solid and water contents are as follows: Dried shavings, 85 per cent of solids, 15 per cent of water; pressed wet shavings, 12 per cent of solids, 88 per cent of water. The quantity of water to be evaporated from 7 kg. of shavings can be calculated as follows: 7.0 kg. dried shavings contains 5.94 kg. solids and 1.06 kg. water; 51.75 kg. wet shavings contains 5.94 kg. solids and 43.5 kg. water. The production of 7 kg. of dried shavings requires accordingly the evaporation of 43.5 — 1.1 = 42.4 kg. of water.

The shavings are dried by means of a direct utilization of combustion gases, obtained by burning coal on a specially constructed grate. On the basis of tests which have been obtained in practice, we can figure on a coal consumption of 0.6 kg. coal for 1 kg. of dried shavings, so that for 7 kg. of dried shavings, corresponding to a quantity of 100 kg. of beets, a coal consumption of 4.2 kg. is necessary. Comparing this coal consumption with that necessary for the total manufacture of raw sugar, which, according to the normal conditions shown in Table IV is 7.5 kg., it follows that the consumption necessary for drying is 5.6 per cent of the total.

The 42-kg. steam obtained by the drying of the shavings has the abnormally high evaporation figure of 10, which can be accounted for by the fact that the loss of

TABLE V—DETERMINATION OF DEW POINT

Theoretical air consumption for the combustion of 1 kg. of coal					9.7 kg. air
Combustion water + water content of the air per 1 kg. of coal					0.5 kg. H_2O
Evaporation of water per 1 kg. of coal = 42 4÷4 2					10.0 kg. H_2O
Total quantity of steam per 1 kg. of coal, 10 + 0.5					10.5 kg. H_2O
Air surplus	1.0	1.2	1.4	1.6	1.8
Air consumption per 1 kg. coal	9.7	11.7	13.6	15.5	17.5
Weight of combustion gases	10.7	12.7	14.6	16.5	18.5
Weight of steam			10.5

Dew-point, deg. C	86	85	83	82	80.5

the exhaust heat is very small, on account of the low exhaust temperature— about 100 deg. C.— of the mixture of the vapors and the combustion gases.

The heat of condensation of the 42 kg. of steam present in the exhaust gases is more than sufficient to supply the heat necessary for the diffusion, preheating of the juice, etc., if the two following assumptions are considered:

a. That the temperature at which the heat can be made available is high enough.

b. That the required percentage of steam can be separated from the mixture of steam and gas.

The dew-point of the mixture of steam and gas is important for the consideration of these two points, as is shown in Table V. The table shows that in practice a dew-point of 83 to 85 must be figured, which means that at this temperature the condensation of steam begins. The percentage of steam condensing is greater the lower the point at which the mixture of steam and gas is cooled. Further calculations show that the heat of about 70 per cent of the steam content can be obtained by condensing the same, if the temperature is lowered 15 deg. below the dew-point— that is, down to about 70 deg. C. This temperature, however, is sufficient for only a small part of the heat consumption of the sugar factory, and it is therefore necessary to raise the temperature by means of a heat pump.

Effect of Drying on Heat Economy

The following considerations show how the heat economy is influenced by the utilization of the exhaust heat from the drying of the shavings and also by the necessary rise in temperature difference.

It is assumed that the mechanical energy necessary for raising the temperature must be generated by means of steam power. A study of Fig. 5 shows that of the 42 kg. of steam contained in the exhaust gases, about 16 kg. can be used in the sugar factory, which must be made available by cooling the mixture of steam and gas to from 75 to 77 deg. C. This corresponds to

Total consumption of electric energy—66 kw.

a steam pressure of only 0.4 atmosphere absolute, which must be raised to a pressure of 1.6 atmospheres absolute if the heating temperature is to be 108 deg. —that is, as high as the temperature of the vapors otherwise used for heating purposes. For this purpose, the driving turbine must produce an energy of 81.5 cal. for 1 kg. of generated steam, at a compressor efficiency of 65 per cent. If the turbine is driven with live steam (of 13 atmospheres absolute and 300 deg. C.) and gives up its exhaust steam to the exhaust steam distributor at a back pressure of 1.75 atmospheres absolute, corresponding to a saturation temperature of 115 deg. C., then at 55 per cent efficiency 55.2 cal. per kg. of live steam is transformed into mechanical energy, and accordingly 0.677 kg. of vapor can be generated by means of 1 kg. of steam.

The operating conditions of the vapor compressor are shown in Fig. 5. It may be seen that a small part of the exhaust heat of the drying plant corresponding to 4 kg. of steam can be made available without a preliminary rise of temperature.

The final result of a program carried out according to Fig. 5 is a steam consumption of 53 kg. of steam per 100 kg. of beets. In contrast to the plan of Fig. 4, this means a saving of steam of 3.9 kg.—that is, 7 per cent. This saving seems to be very small, but is explained by the fact that in order to obtain the highest possible capacity of the driving engine of the heat pump, no attention has been paid to the installation of the preliminary boiler of Fig. 4. When it is considered that even without the use of the exhaust heat of the drying plant a lower level of steam consumption—viz., 48—can be reached by increasing the number of the preliminary boilers arranged in series, the conclusion may be justified that, basing the operation on steam economy alone, the use of the exhaust heat from the drying of the shavings produces no economical result.

More favorable results are obtained by providing the primary and secondary evaporation systems with a vapor compressor. In this case a much larger part of the exhaust heat of the drying plant can be used and the boiler would have to generate only a part of the steam necessary for covering the losses. Such a working plan is shown in Fig. 6, according to which 49 kg. of steam besides 6.6 kw.-hr. per 100 kg. of beets is necessary. If the electrical energy must be generated

by means of steam power in a condensing turbine, the entire steam consumption amounts to 49 kg., which is as great as when no vapor compression is used.

However, with hydro-electric energy, conditions may be entirely different, and the relation between energy and coal consumption, which is based upon the efficiency of the power engine, is eliminated. In that case it is possible to reduce the operating costs by one-half or more of the costs required with steam operation exclusively.

Fields of Application of Evaporation by Compression

Summing up the conclusions derived from a consideration of the points outlined above, the prospects for a successful application of evaporation by compression do not appear especially favorable, if judged only from the viewpoint of heat economy. In practice, however, conditions are frequently not such as to make the evaporation a secondary operation utilizing exhaust steam. Often the problem arises how to operate the evaporation process independent of other operations in a most economical way. However, despite the fact that from a thermal standpoint nothing would hinder the multiple-effect evaporator from being operated in a manner as economically favorable as the compression evaporator, practical objections often arise against such an installation.

One principal objection to multiple-effect installations is the fact that the temperatures in the various stages are different. This results in objectionably high pressures in the first stages under certain conditions. Often multiple-effect evaporation cannot be used in any event, this being the case if, in consideration of the properties of the final product and of the physical and chemical conditions of the liquid to be evaporated, a certain evaporation temperature has to be chosen, which temperature can be raised only within small limits. In such cases the compression system has in many instances great advantage from the standpoint of heat

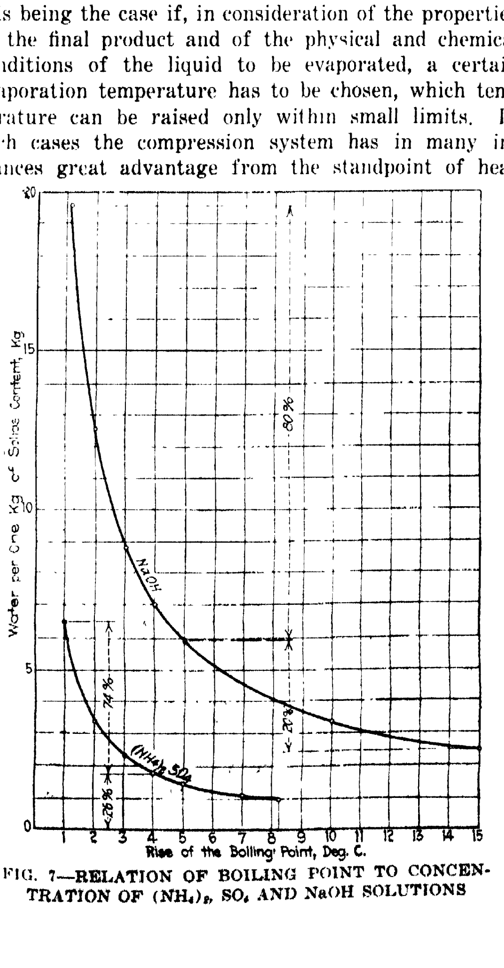

FIG. 7—RELATION OF BOILING POINT TO CONCENTRATION OF $(NH_4)_2SO_4$ AND NaOH SOLUTIONS

economy. As an example, the evaporation of milk, fruit juices and tanning materials may be chosen. In inorganic chemistry, there are also many such examples.

The economy of compression evaporation can be questioned if we have to deal with a considerable rise of the boiling point. But even in such cases, larger installations can be favorably operated if we take into consideration that the rise in the boiling point is a function of the concentration. In order to explain this relation, let us turn to Fig. 7. A distinction must be made between the two principal cases. In the first, only the concentration must be raised by evaporating without a separation of the dissolved substance; in the other, the problem is to separate the dissolved substance in a solid form. In the latter case the boiling point

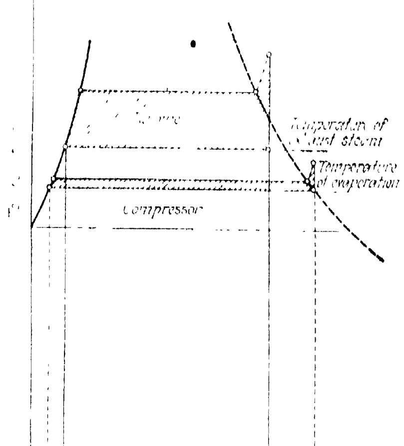

FIG. 8—ENTROPY DIAGRAM

rises to a maximum, at which point the separation of the salt begins and then remains constant. The curves, which represent the dependence of boiling point on concentration, always have a certain resemblance in character, and there are universal laws which determine this function. The figure shows the boiling conditions of caustic soda and ammonium sulphate solutions. The first case involves a concentration of the solution and the second a separation of salt. The curve shows that the rise in the boiling point, corresponding to the concentration at the start, is usually low, and that a considerable percentage of water can be evaporated with only a small rise in the boiling point of 4 or 5 deg. The practical conclusion that must be drawn from this is that the evaporation process should be done in two separate stages: A preliminary concentration in which the greater part of the water is evaporated in the compression evaporator under a slight rise of the boiling point, and a secondary evaporation with a greater temperature drop in a single- or multiple-effect evaporator heated in the usual manner.

The conditions are especially favorable for the compression evaporator, when evaporation must be done at low temperatures and when, at the same time, steam must be supplied to a heating plant. It is not possible to use the exhaust heat of the evaporator directly, because the temperature would be too low. On the other hand, in the case of compression evaporation, the exhaust steam of the driving turbine can be fully utilized at any desirable pressure—that is, at any desirable temperature. A plan of operation is shown

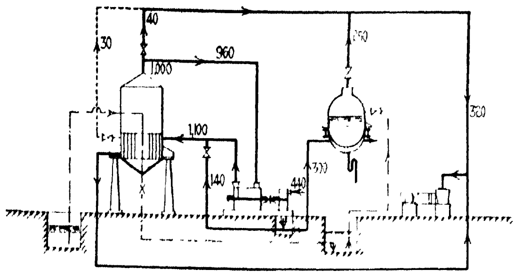

FIG 9—SYSTEM UTILIZING EXHAUST STEAM FROM TURBINE

in Fig. 8, where, in the temperature entropy diagram, the operation of the compression and the driving engine is shown, and where the temperatures and relation of heat economy can also be seen.

An example of this basic arrangement which has been put into successful operation in practice is shown in Fig. 9.

Evaporating Fruit Juice

A fruit juice of a very important foodstuff industry must be concentrated to a sixth part of its original weight. The final product is of such a thick consistency as to make it impossible to evaporate the last portion of water in a tube evaporator. For this purpose a steam-jacketed bowl heated with a sufficiently great drop in temperature seems to be better adapted. The evaporation temperature must be about 60 deg. C.

The evaporation is done as follows: The preliminary concentration of 1:3 is done in the compression evaporator, then the final concentration of 1:2 in a bowl. Eighty per cent of the water is evaporated in the compression evaporator; 20 per cent in the secondary evaporator. Both evaporators are operated under the same vacuum. The exhaust steam of the driving turbine of the compressor is exhausted at a pressure of 5 or 10 lb. gage and to a large extent serves to heat the secondary evaporator. The remainder serves to cover the loss by radiation.

The installation shown in Fig. 9 evaporates altogether 1,000 + 250 = 1,250 kg. of water per hour. Formerly, when using a single-effect evaporator, 1,500 kg. of steam per hour was necessary. The new operation reduces the consumption to 440 kg. per hour, which means a saving of 70 per cent of the former steam consumption. Fig. 10 is a photograph of an installation which operates according to the plan shown in Fig. 9, but which has a much larger evaporation capacity. Fig. 11 shows an installation in Switzerland for the vacuum evaporation of milk. This plant is electrically operated, on account of the comparatively high cost of coal. Table VI shows results of operations over long periods. The specific figures on the evaporation capacities are therefore correct for normal operations.

TABLE VI—RESULTS OF A MILK EVAPORATION PLANT

Concentration	1:5
Height of the barometer, mm	735
Vacuum evaporator, mm	585
Vacuum heating chamber, mm	545
Estimated temperature of vapors, deg. C	60.3
Measured temperature of vapors, deg. C	59
Temperature of heating steam, estimated, deg. C	65.3
Temperature of heating steam, measured, deg. C	65
Duration of the evaporation	6 hr., 25 min
Average evaporation per hr., kg	1,680
Voltage	245
Intensity of current, amp	92
Energy consumption, kw	31.4
Water evaporation for 1 kw.-hr., kg	53.5
Water evaporation for 1 hp.-hr., kg	45.0

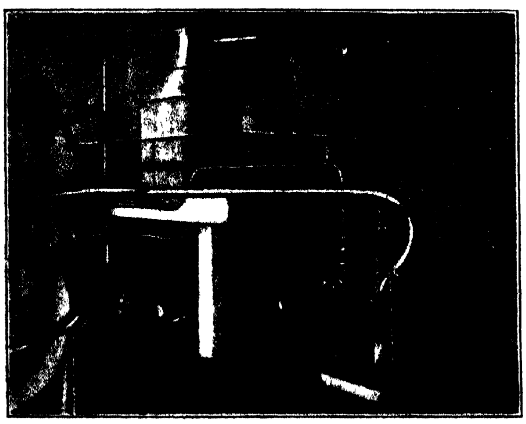

FIG 10—INSTALLATION OPERATING ON ARRANGEMENT SHOWN IN FIG. 9

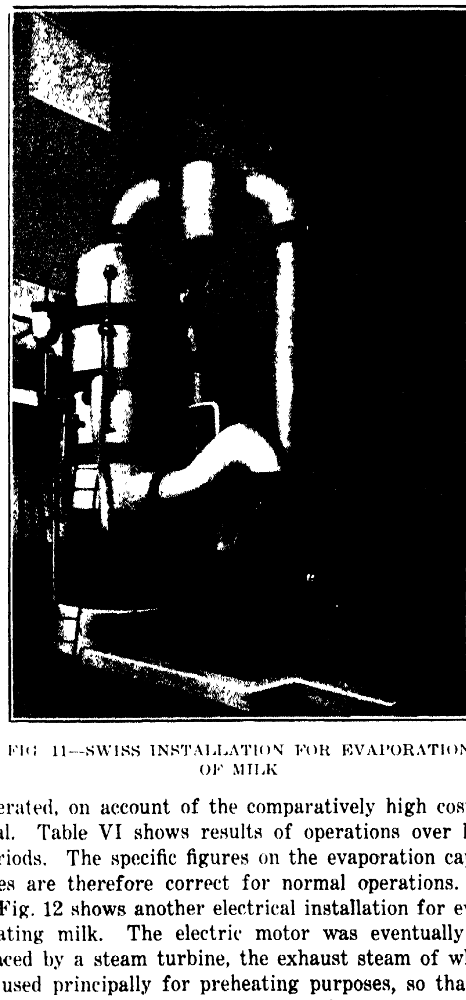

FIG 11—SWISS INSTALLATION FOR EVAPORATION OF MILK

Fig. 12 shows another electrical installation for evaporating milk. The electric motor was eventually replaced by a steam turbine, the exhaust steam of which is used principally for preheating purposes, so that in this case the operation by means of steam proved to be much superior to the electrically operated plant.

Résumé

The field of operation for the compression evaporator is limited. Compression evaporation may possess very considerable advantages if operated in its proper field. Examples on conditions which justify its use are:

Where the evaporation has to be done at a certain temperature because of the properties of the liquid, which means that it has to be done in a single-effect evaporator.

Where the direct use of the vapors of the evaporator is not possible on account of special conditions mentioned above—the temperature is too low, or because

the vapors carry over volatile acids and therefore it would not be possible to use them.

The characteristic of the compression evaporator which should be emphasized in connection with the use of exhaust steam is *that the temperature at which the exhaust steam is used can be made entirely independent of the temperature of evaporation in the evaporator.*

Economy of the Compression

The capacity of the evaporator in respect to the evaporation of water depends primarily upon the extent of heating surface, the viscosity of the liquid to be evaporated, and the construction of the evaporator, especially with regard to good circulation.

On the other hand, in the case of vapor compression, the efficiencies of the compressors must be considered, and this, as previously mentioned, has a great bearing on the heat economy. Three special types of compressors have to be considered.

a. Piston compressor (including rotary blowers).

b. Turbo-compressors with steam-driven turbine (the electrical drive not to be considered).

c. Injector-compressors.

As a rule, the turbo-compressor is considered the most advantageous for the compression of vapors. This view is true in many cases, but not in all. The turbo-compressor allows a slight rise of temperature with good efficiencies of 60 to 65 per cent. As the rise in heat is effected by arranging separate stages in series, the efficiency can be kept at the same level independent of conditions of compression. There is no limit to the increase of the transmitted vapors as far as practical considerations go, especially when considering the possibility of arranging several units in parallel. On the other hand, the capacity of the compressor is limited. In case of small quantities of vapors, the turbo-compressor can either not be operated at all, or only at a high cost and low efficiency.

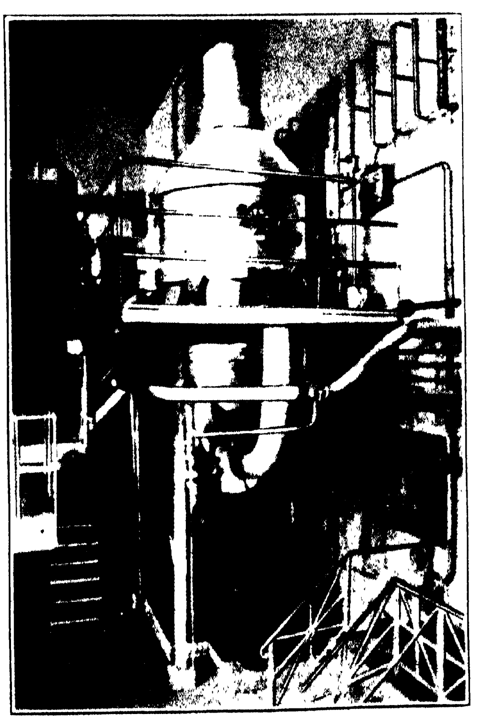

FIG. 12—ELECTRICALLY OPERATED INSTALLATION FOR EVAPORATION OF MILK

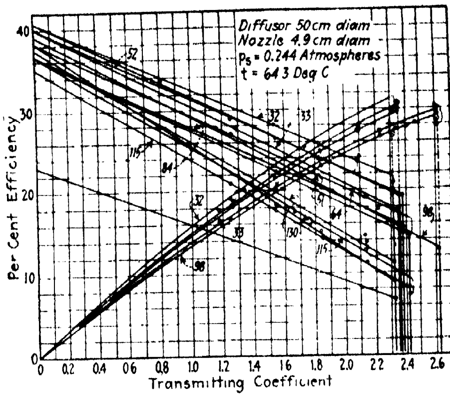

FIG. 13—THERMODYNAMIC EFFICIENCY OF INJECTOR-COMPRESSOR

The piston compressor can be built for very small quantities as well as for larger quantities of vapor. The dimensions of the piston compressor would be too great in practice for very large quantities of vapor. In that case the engine would also be too expensive in comparison to the turbo-compressor. If it is desired to evaporate under small temperature drops (and that is generally the case) then the efficiency of the piston compressor is low because the mechanical friction is great, compared to its usefulness.

The injector-compressor is of some importance. This from a thermodynamic viewpoint represents a simplification of the energy transfer of the turbo-compressor with steam-driven turbine. The transfer of energy of the turbine is characterized by the following phases: Potential energy, kinetic, mechanical, kinetic, potential. With the injector-compressor, the third stage mentioned above is eliminated and the kinetic energy is transformed directly into energy of velocity, and the latter, after being mixed with the vapors, is immediately changed back into kinetic energy. The evaporation, in the case of the injector-compressor, is in no way limited. It would be of interest to compare the three possible methods of compression in respect to their suitability for compression evaporation. This can best be done by considering the function which, bearing in mind the above question, must be chosen as the relation between capacity and that difference of saturation temperatures depending on the difference in pressure. The characteristics and efficiencies of turbo- and reciprocating compressors are known. This is not so true in the case of the injector-compressor, concerning which accurate and complete figures are not known or have not been published. This can be understood when it is remembered that correct dimensioning of the injector-compressor is of much greater importance than technical experience and practice. A consideration of the injector-compressor at this point, therefore, is made possible only by the fact that the transfer of energy has been thoroughly studied in previous theoretical and experimental investigations. It is impossible to say at this time whether the maximum conditions which have been determined can be considered as final, as the experiments have not been fully completed.

Fig. 13 shows the characteristics and efficiencies which were obtained when the dimensions of the mixture and compression apparatus were systematically changed; as abscissa, that quantity of steam was chosen which is transmitted by 1 kg. live steam; as

ordinate, the temperature rise (always based on saturation)—i.e., the thermodynamic efficiency. Characteristic of all curves is the fact that with increasing temperature the transmitting coefficient remains constant until a maximum is reached, and that then there is a sharp break in the curve and the delivery coefficient approximately decreases linearly with rising temperature. The efficiency reaches a maximum of about 32 per cent.

Comparing the characteristics of the different forms of compression, in Fig. 14, it is observed that, in the case of the turbo-compressor, there is an appreciable increase of the quantity of steam transmitted when the rise in temperature may be smaller than under normal conditions of operation. If, with increasing concentration the heat transfer, and therefore the evaporation, becomes smaller, a partial compensating effect takes place until the maximum of the increase in temperature is reached. Then, however, further decrease of the evaporation efficiency brings us into a field where the compressor "pumps" and the operation is more or less at a standstill. The pumping can be avoided by leading back a part of the vapor from the pressure side to the suction side, but this can be done only at a sacrifice of the efficiency. Attempts to avoid pumping

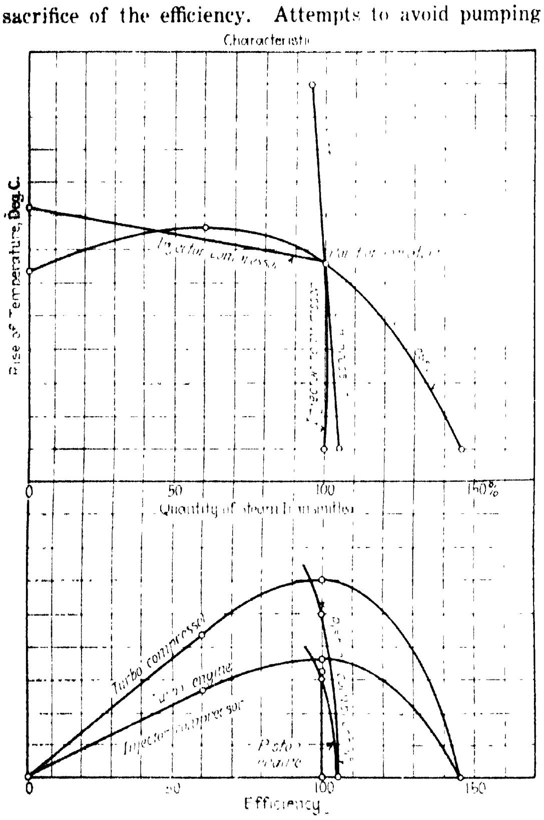

FIG. 14—COMPARATIVE CHARACTERISTICS OF DIFFERENT FORMS OF COMPRESSION

by changing the number of stages of the compression complicates the operation. If the evaporator is so dimensioned that pumping does not occur, the turbo-compressor has various characteristics favorable to its practical operation.

The piston compressor is characterized by an approximately constant transmission of steam at variable temperatures. The slight decrease in transmission at increasing temperatures is explained by the fact that with increased compression the volumetric efficiency

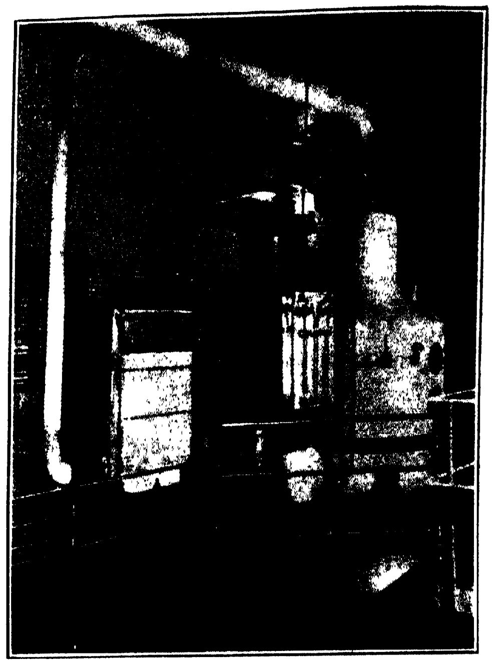

FIG. 15—VACUUM EVAPORATOR WITH INJECTOR-COMPRESSOR

decreases. The approximate constant of the steam transmission will last as long as the required capacity of the driving engine.

The injector-compressor shows a constant on the quantity of steam transmitted up to a certain rise in temperature; with a slightly increased temperature, the quantity of steam transmitted decreases. On considering the efficiencies, it may be seen that the injector-compressor under normal conditions of operation does not show up much more unfavorably than the turbo-compressor. For this reason the injector-compressor must be considered especially in the case of plants of smaller capacities in which a turbo-compressor cannot be used.

An injector-compressor cannot be used when the exhaust heat of the evaporator must be used at a temperature which is higher than the required temperature of evaporation and which is also higher than the temperature of the heating system. In that case a turbo-compressor with steam-driven turbine must be considered. Vacuum evaporating plants with injector compressor have been installed in many cases. Fig. 15 shows such a plant which evaporates 1,300 to 1,500 kg. of water per hour.

CONCLUSION

The above discussion touches on the principal points which are of importance for the consideration of an economical application of compression evaporation. It has been shown:

1. That often *general* conditions of heat economy existing in a plant are of greater importance for the choice of a system of evaporation than the economy of the evaporating system itself.

2. That for compression evaporation cases where the evaporation must take place at a certain temperature should be specially considered.

3. That for the compression of vapors, a choice must usually be made between a turbo-compressor and injector-compressor, and that piston compressors are of smaller importance.

Aims and Purposes of the American Institute of Chemistry

Establishment of Professional and Economic Community of Interest, Followed by Professional Recognition and Acknowledged Standing

BY F. D. CRANE
Newark Technical School, Newark, N. J.

THE existence, no less than the prosperity, of the British Institute of Chemistry has stood for years as a challenge to American chemists. A similar society has been talked of, reported on — and the reports pigeonholed. The New Jersey Chemical Society has been urged to try it as a state matter, but some of the most interested people have been widely scattered, and many were sure that only a national society with state chapters could live. There was a strong undercurrent of belief that chemists themselves were not quite competent to say who was a chemist—indeed, the unchallenged claim was made that no one knew what a chemist was.

And now, without in the least deciding *what* they are, some chemists are very certain that they are through with being the one learned profession in the land with no economic organization. They are fed up with "hanging separately"; it can be no worse and surely will be more companionable to "hang together." The chemists made temporary organization permanent on Feb. 5, 1923, and the American Institute of Chemistry is offering membership to all who consider themselves chemists.

Should it be supported? There are good reasons why it should, the main one, the main reason for its existence, being that it is, first and foremost, an economic organization.

WHAT THE INSTITUTE OFFERS

It takes a wholly unoccupied field in American chemistry, offering neither opposition to nor competition with any existing chemical society. It just says: "Are you a chemist? You are welcome to our fellowship; you will find other chemists and you can classify yourselves; we are united for our common good." That is something new in American chemistry; no other group has put being a chemist first. The Institute does this because the establishment and recognition of fellowship, of professional and economic community of interest, is its main purpose.

The next step, which must follow, is professional recognition and acknowledged standing. No other group, asking years of study and practice to attain proficiency and upon whose opinions life or property may depend, has ever rested so long without taking proper means to safeguard its members in the practice of their profession.

In some states a chemist may not get one hair legally abbreviated except at the hands of a licensed practitioner; in many his dead and empty arteries may not receive their due portion of the formaldehyde he, when living, may have made, except as it is administered by a state-licensed operator. In nearly all, perhaps by this time in all, states his accounts, whether he be alive or dead, will go smoothly before courts and tax collectors only if they are presented by a certified public accountant— that is, by a state-licensed bookkeeper. Meanwhile the chemists, "in dispersed phase," take what is handed them and are in economic competition with anyone who chooses to pass out cards printed "chemist" or who may have assumed a Doctorate on no firmer grounds than a marked foreign accent. "William's college degrees," so liberally bestowed in the early days of the Chemists' Club, when the dusky William "doctored" everybody, might stand today, to the man in the street, as well as any. How can anyone say whence they came when the holder bloweth as he listeth?

TO ESTABLISH CHEMISTRY AS A PROFESSION

Slowly, perhaps, but surely, the American Institute of Chemistry is going to put the practice of chemistry as a profession on as certain a foundation as any other, making that foundation broad enough to hold every honest practitioner. This is not a new duty; it is a neglected one. The profession which lacks the gumption to recognize itself deserves obscurity.

Now that chemistry has ceased to be a war baby, it again sells in a buyer's market. "The way to make money is to get hold of a creative enthusiast and keep him on wages" is a recipe for riches only as long as that kept fellow spends neither some of his time nor a little of those wages in finding out what his creation is really worth. Many chemists today are on as economically false and unsound a basis as the average farmer, and since there aren't enough of them (and their wives) to elect a chemists' bloc, it is unlikely that there will be any Chemists' Chemical Banks, with easy loans, set up for their supposed benefit. Supply and demand rule mobs but serve armies; an organized profession can foresee demands and prepare to fill them, and can locate deficits and surpluses and interchange them far better than individuals. Sellers of ideas and services too often get what is left after all else are well paid simply because they know of no better market than the one at hand. The American Institute of Chemistry proposes to study impartially the markets for substances, services and ideas, putting each tub on its own bottom and then seeing that it has a fair chance to stand. It will succeed in this, because as an economic fellowship of recognized ability it will enter a seller's market with offerings worth their price because guaranted as to quantity and quality.

Manufacture of Cane Sugar

Although the value of cane sugar has depreciated considerably, an increase in the quantity produced in the United States during 1921 is recorded in the reports of the Bureau of the Census. The total value of products for 1921 amounted to $23,153,000, as compared with $57,741,000 in 1919, representing a decrease of 59.9 per cent over a 2-year period. In compiling these statistics refineries making refined sugar from imported or domestic raw sugar have not been included, but only those manufacturing sugar, sirup and molasses directly from the cane.

The decrease in value of cane sugar has resulted in a decrease in the number of persons employed. Many of the smaller factories in operation in 1919 were reported in 1921 as idle or out of business. The decrease in number of those employed, therefore, cannot be attributed entirely to the fact that the manufacture of cane sugar is a seasonal industry, for in December, the month of maximum employment, there were 14,034 wage earners and in February and March, the period of minimum employment, approximately 1,866 — the minimum representing 13.3 per cent of the maximum.

Legal Notes

By Wellington Gustin
Of the Chicago Bar

Goods in Bankruptcy

Return of Merchandise Stored Not a Preference in Favor of Creditor

Some interesting propositions are involved in the bankruptcy case of Rosenbloom Leather Co. on petition of the Consolidated Rubber Co. The case came up on a petition to review an order of the referee denying the Rubber company the right to reclaim certain rubber products in the hands of the trustee in bankruptcy which were in the physical possession of the bankrupt at the time of the filing of the involuntary petition. 280 Federal 139.

No Absolute Sale Involved

The bankrupt was engaged in business in Michigan and apparently had contract for the sale of the Rubber company's products in the state. The Rubber company is an Ohio corporation and was not authorized to do business in Michigan. The bankrupt was to sell the Ohio corporation's products in Michigan at a price fixed by the latter, collect the money and remit the price less his compensation, which was fixed as a commission of 12½ per cent. These provisions were strictly carried out, and the court found that the facts did not constitute an absolute sale to the bankrupt.

The referee held that the transactions between the parties was a conditional sale to the bankrupt, for resale by him, and therefore void as regards the reservation, because not filed for public record as required by Michigan law; and he further held that if such agreement would thereby create an agency in the bankrupt to sell such property for the Consolidated Rubber Co., the latter would be barred from recovery by reason of its failure to obtain a license to do business in Michigan as required by statute of that state, invalidating the contracts of foreign corporation violating such statute in this respect.

Goods in Question Only Stored for Rubber Company

Now further facts disclosed showed that within 4 months prior to bankruptcy the bankrupt ceased selling the Rubber company's product and it was agreed between them that the goods which then remained with the bankrupt should be stored on the premises for the Rubber company. These were the goods involved in this suit.

The U. S. District Court held that the effect of this settlement was to release both the Rubber company and the bankrupt from their respective obligations under their earlier agreement, and to restore them to the positions occupied by them before its making. After this settlement the court held the title to this merchandise was vested in the Rubber company, if not before. This disposed of the question under the original contract between the parties as to whether the agreement was one of absolute sale with an attempted retention of title, operating as a chattel mortgage lien, in the Rubber company, a contract of conditional sale, with title remaining in the Rubber company until resale by the bankrupt, or an arrangement of pure agency.

This settlement did not effect a voidable preference in favor of a creditor. The court says on the point: "The contract under which the goods were delivered to the bankrupt having been made prior to the statutory 4 months' period before bankruptcy, for a present consideration, and the rights of the parties with respect thereto bring valid and enforceable as between them, the surrender of possession of this property was merely a delivery thereof to its owner, to which the latter was entitled, and was not a transfer by the bankrupt of his property to one of his creditors and hence such transfer did not constitute a preference." 25 Sup. Ct. 306.

Failure to Obtain License Does Not Prevent Recovery of Property

Again, the court said the referee was in error in holding that, if the relation between the parties should be treated as that of principal and agent, and not of vendor and vendee, the Rubber company would be deprived of the right to recover by its failure, as a foreign corporation, to comply with the statute of Michigan requiring such corporation to obtain a license to do business in the state and making void all contracts entered into by any such corporation in default. It is the settled rule of the Michigan Supreme Court, by which the federal court in that district is bound, that a foreign corporation which has not obtained the necessary license to do business in Michigan does not thereby lose the right to protect and recover its property from loss or injury, where such right does not depend upon a contract made in violation of this statute, but arises irrespective and regardless of any contractual rights, and that under such circumstances it does not forfeit such property but may recover possession thereof, if otherwise entitled to it, in a proper tort action, such as replevin.

There being no fraud shown or claimed in making of either the original agreement or subsequent settlement, the court said the order of the referee must be set aside.

Perkins Glue Patent Not Infringed

Application of Second Step of Process to Natural Base Permissible Under the Law

Further litigation, with a most recent decision, over the Perkins reissue patent No. 13,436 (original No. 1,020,655) comes from the United States Circuit Court of Appeals, Second Circuit. Suit was begun in the District Court by the Perkins Glue Co. against the Standard Furniture Co., of Herkimer, N. Y., and there resulted in a decree for the plaintiff. This decree has now been reversed on appeal, and the cause remanded with directions to dismiss.

In the case at bar the court points out the results reached on this patent in the Circuit Court of Appeals in the case of Solva, etc., Co., vs. Perkins, etc., Co., 251 Fed. Rep. 64.[1] These results were that the process disclosed by Perkins consisted of two parts or steps, and that each of the steps considered by itself was old, but the product was new and patentable. Without agreement or disagreement with this result the court here accepted it for purposes of present decision.

After the decision in the Solva case the mandated court ruled that only these claims remained valid

[1]See also *Chem. & Met.*, vol. 28, p. 124, Jan. 17, 1923.

"which included the two steps [of the process] and only when their use results in Perkins glue, together with such additional claims as count on such glue as a product of the two steps and no others." Subsequently to this Perkins disclaimed *inter alia* from claims 13 and 38 of the reissue patent "any process of making glue excepting where the starch or starchy product of carbohydrate subjected to the process is degenerated to the extent described in" the reissue. 280 Federal 729.

In the present case it was claimed that defendant procured starch so degenerated as to be in a condition equivalent to starch treated by Perkins' first process, and then gave to that substance Perkins' second process and so obtained Perkins' product.

Natural Product Has Properties of Degenerated Starch

Perkins' expert witness defined degeneration as "a certain proportioning of resulting viscosity, cohesiveness and adhesiveness." But defendant's evidence showed that the starchy substance or carbohydrates, called viscamite, which it used as a base for its alleged infringing glue, is a natural product, and that it received no chemical treatment whatever. The court said the fact was that the earth had been found to produce a starch which plaintiff admitted is the exact equivalent of what Perkins made by his first process.

This product of nature cannot *per se* be covered by any patent, and it certainly is not the result of any process devised by Perkins, says the court. Therefore, accepting the decision in the Solva case referred to above as interpreted and apparently acquiesced in by plaintiff, there could be no infringement, because the defendant is not using a glue which is the result of both steps of Perkins' patent.

But going further than this and examining the process used by defendant in making its glue, the court found that "starting with the natural starch base, a mixture is made ultimately containing about two and one-third parts of water to one part of starch base by weight and about 3 per cent of caustic soda based on the weight of the starch."

The court found that some accident of nature or the skill of agriculturists has produced and put on the market a cassava starch of that degree of viscosity, etc., which Perkins achieved by his degenerative process.

Applying Second Step of Process to Natural Base Does Not Infringe

With such starch the defendant by using methods as old as the Belgian patent to Gerard of June, 1874, has produced a substance which plaintiff says is Perkins glue. Perhaps it is in result, says the court, but it cannot be the same thing in a patentable sense because nature has supplied the base and Gerard the process. The only reason that justified prior courts holding Perkins' product patentably new was by finding it the peculiar result of a combination of two processes severally old. There was no such foundation for a finding in this case. Nature or the farmer (so to speak) has superseded the first half of Perkins method, and the second half was not new; the product of a natural base treated by an old process cannot be an infringement under any view of the law.

"Plaintiff has defined its product as a 'new vegetable glue as good as animal glue for veneering.' We think that this definition is not advanced by embodying it in a laudatory phrase descriptive of intended result.

"We may agree that Perkins disclosed a 'new vegetable glue'—i.e., a manufactured product. There are some manufactured products so broadly new that the same thing, however produced, may be within the invention's broad range of equivalents. This is a question of fact, but on the prior art and the evidence herein as to modern cassava starch, Perkins vegetable glue is not such a product. We think, therefore, that the lower court fell into error in substantially paying no attention to the nature of defendant's starch base, and it is directed that the decree be reversed . . . with directions to dismiss the bill . . . on the ground of non-infringement.

The Sulphur Industry of the World

For some years Italy has been the greatest exporter of sulphur. During the past 3 years, however, the United States has become the chief source of supply, owing to the exceptionally low cost of production. Japan now ranks third in importance as an exporter of this commodity. Although free or native sulphur is devoted to many different uses, it has been estimated that more than half the consumption is in the manufacture of sulphuric acid. Large quantities are also used in the sulphite process of digesting wood pulp for paper manufacture, as a fungicide for grape vines and hops and as a fertilizer, insecticide, fumigant and sheep dip. Moreover, the vulcanization of rubber, the manufacture of matches, explosives, dyes and cements, as well as photography and medicine, all draw heavily upon the sulphur supply.

During the war Japan, which next to the United States and Italy is the chief producer and exporter of sulphur, greatly increased its output. A record of 116,000 tons was reached in 1917, as compared with an average of 49,000 tons in previous years. Practically all the sulphur produced in Japan was exported previous to 1917, as there is normally very little demand for it in the home market. Since the war, however, both production and exports have decreased in large measure.

Of the total Japanese sulphur exports, 45 per cent went to the United States, the largest consumer, prior to the war. For the most part, these shipments were used in the paper-making industry of the Northwest. The difference in freight charges in shipments across the Pacific, in comparison with those from Louisiana and Texas, is the cause of the large amount still imported from Japan. The opening of the Panama Canal, however, has made the Gulf ports easily accessible to the Pacific Coast and in future the American producing regions can doubtless satisfy the home market. Australia had also relied upon Japan previous to the war for sulphur supplies, as she imported 35 per cent of the total Japanese output. However, in 1920, the last year for which figures are available, Japan exported the larger part of her reduced output to India, replacing almost entirely the Sicilian product.

American sulphur has recently been exported in large quantities. Previous to 1917, an average of 60,000 tons was shipped annually to foreign markets. Of this amount, 88 per cent went to three countries alone—45 per cent to France, 31 per cent to Canada and 12 per cent to Germany. In the first 9 months of 1922, statistics show that sulphur exports from the United States amounted to more than 400,000 tons and although each country imported a smaller quantity than previously, the export market has expanded so that these three countries used only 55 per cent of the total amount.

Synopsis of Recent Chemical & Metallurgical Literature

Byproducts Oven Heat Balance

D. S. Chamberlain and E. W. McGovern, of Bethlehem, Pa., published in *Gas Age-Record* for Feb. 17, 1923, a complete heat balance for a battery of byproduct coke ovens which gives a good check on current figures for the heat loss of endothermic reactions in the change of coal to coke.

The data used in this heat balance were obtained from a battery of Koppers ovens, which are in this case unique in that they have 106 ovens per battery. As this is the largest number of ovens per battery known to us, this operation is conspicuous in that the control is so perfect and the results so uniform. The results obtained from the following data indicate the rapid development in the construction of regenerative byproduct coke ovens.

(Basis: One gross ton of coal, dry.)

Heat Available Input	B.t.u.	Per Cent. Input
(1) Latent heat in coal	30,369,920	86.71
(2) Sensible heat in coal	3 517	0.01
(3) Latent heat in fuel gas	3,011,840	8.53
(4) Sensible heat in fuel gas	3,065	0.01
(5) Sensible heat in preheated air	1,638,575	4.74
Total input	35,026,917	100.00
Heat Distribution Output		
(1) Latent heat in coke	21,571,175	61.61
(2) Sensible heat in coke	1,240,144	3.55
(3) Latent heat in foul gas	6,760,000	19.33
(4) Sensible heat in foul gas	435,108	1.26
(5) Total heat going out stack	1,102,690	3.16
(6) Latent heat in tar	1,347,200	3.85
(7) Sensible heat in tar	19,198	0.05
(8) Heat absorbed in tar formation	45,168	0.13
(9) Radiation and convection losses	399,840	1.14
(10) Latent heat in light oil in foul gas	300,037	0.86
Total output	33,223 860	
Unaccounted for	1,803,057	5.16
	35,026,917	100.00

1,803,057 ÷ 2,240 = 804.9 B.t.u. per lb. of dry coal, the heat required to coke one pound of coal.

The difference between the heat input and the heat output, as developed from the preceding data, amounts to 804.9 B.t.u. per pound of coal. On a percentage basis of 5.16, this figure comes within the range of results as determined by Constam and Kolbe. As the endothermic reactions, taking place in the coking operation, vary with the type of coal, the indication is that the heat required to coke such mixtures as used in the byproduct coke ovens in the United States is greater than that required for English coals. The B.t.u. value of 804.9 was practically checked by a heat balance run on a battery of Semet-Solvay ovens in the early part of 1922, at which time a B.t.u. value of 788.0 was obtained, amounting to a heat loss of 5.06 per cent.

In conclusion, the advance in the development of the byproduct coke oven, in so far as a heat balance is concerned, will be made evident by a decided reduction in the latent heat in the fuel gas. This will be brought about by an oven construction that will reduce the total heat going out the stack as well as reduce the radiation and convection losses. In other words, the total gas used as fuel gas for heating the battery will eventually be reduced to a percentage of 35.0 or less.

Important Articles In Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

American and English Ball Clays

The Bureau of Standards has recently completed a study of the twenty-one varieties of ball clay that are used in the largest quantities in the manufacture of china, semi-porcelain, electrical porcelain, tile and sanitary ware. The results of this study have been made the subject of a recent publication by the bureau.

Determinations were made of the following data: Water of plasticity, amount passing through a 120-mesh sieve, shrinkage when dried, rate of flow of slips, cohesion when plastic, dry transverse strength when mixed with an equal amount of flint, time required to oxidize carbonaceous content at 750 deg. C., burning behavior, porosity and volume changes from Orton Seger cone 01 to cone 12 and coloring effect in a standard body.

The American clays were found to be much cleaner than the English clays and contained less coarse mineral matter and dirt which would be removed in lawning the body after blunging. The Kentucky clays were almost free from such material, and the Tennessee clays contained only a small amount, while the English clays were less desirable in this respect.

No great differences were noted in water of plasticity, the range of variation falling within a few per cent. The Dorset clay exhibited the highest shrinkage. All the clays studied warped in drying, but none of them developed cracks.

The transverse strength of equal mixtures of the clays with commercial potters flint was determined to give a better indication of the comparative bonding power of the clays in a body than would be indicated by the modulus of rupture of the clay alone. The average modulus of rupture of the Tennessee clays tested was 366 lb. per square inch, the Kentucky clays averaged 282 lb. per square inch, the clays from Dorset, England, 405 lb. per square inch, the Devonshire clays 443 lb. per square inch, and English clays, whose exact source was not known, 419 lb. per square inch. In general the English clays were stronger than the domestic, but two of the American clays compared favorably with the average English clay.

From the results obtained the rate of flow of slips from the efflux viscosimeter did not appear to be a valuable criterion of the inherent plastic qualities for use in comparing ball clays.

STRENGTH AND BURNING BEHAVIOR

The cohesive strengths of the plastic clays were determined at different water contents and are shown graphically. These results showed no distinctions which compared with the value of the clays for jiggering, as judged by practical potters.

Some of the English clays are very high in carbonaceous matter, 11 hours being required in two cases to remove completely the black core from specimens 1¼x1¼x2 in. The clays from Devonshire as a class required the longest time for oxidation. The Dorset clays and those from Tennessee contained a moderate amount of carbonaceous matter, while the Kentucky clays contained but little. It was noticed that there was a relationship between the amount of carbonaceous matter and the strength when dry, the more carbonaceous clays usually being stronger.

The burning behavior of the American and English clays was radically different. The English clays vitrified at a low temperature and remained almost constant in porosity and volume up to cone 12. No evidence of over-

burning was noticed at that temperature. There was some variation in the burning behavior of the clays from Devonshire, but the Dorset clays underwent practically the same changes in firing. The American clays showed a gradual reduction in porosity from cone 01 to cone 12. Tennessee ball clay No. 5 was the only domestic clay which vitrified at cone 8. Tennessee No. 3 matured at cone 10, and Tennessee No. 11 and Kentucky No. 4 at cone 12. The other two Kentucky clays studied were not vitrified at cone 12. Throughout the firing range studied the American clays were constantly changing in volume.

General Results

In the standard body the Tennessee clays as a class showed the best color. The Kentucky and Devon clays were fair in this regard, while the Dorset clays were comparatively poor in coloring effect.

Although the English clays have a more desirable firing behavior and greater strength when dry, the American clays contain less material to be removed in body preparation, contain less carbonaceous matter which may lead to trouble in firing, and burn to a better color in the body. Because of their better color they may be used in larger quantities, thereby overcoming in a measure their lower strength. With a slight adjustment in flux content of the body they may be successfully used to replace the English clays.

All of the results are given in tabular form and graphically when feasible. A detailed description of each individual clay is given, and a classification of ball clays based on their properties has been drawn from the results of the work.

(Paper 227, by H. H. Shotwell. The complete paper may be purchased from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 10 cents).

Distilling Coal Tar in Europe

In the Feb. 10, 1923, issue of *Gas Age-Record*, R. Furness discusses in some detail the current tendencies in coal-tar distillation practice in Europe, with particular attention to the situation in England. A special point is made of the increased profit which may be realized by the tar producer if he carries on at least partial distillation in his own plant and does not sell the crude product.

Mr. Furness' article may be summed up as follows: The increased tendency toward decentralization of the tar distillation industry is a marked feature of European practice today, and is one which could advantageously be adopted in America. Special stills, which combine ease and cheapness in running, are available, and a broad fractionation into light oils, creosote oils, anthracene oils and pitch is effected with the greatest simplicity.

It has been shown that there are well-marked applications for these products of broad fractionation, and that the prices ruling are well maintained and represent several times the value of the crude tar, such as is sold to a central distillation plant.

If the producer of tar considers it economically justifiable to proceed some distance further and win from the above-noted broad fractions such derivatives as naphthalene, carbolic and cresylic acids, anthracene paste, etc., he is always sure of a ready market. New applications of all these products are constantly appearing. Even if hydrogenation of naphthalene and of phenol fail to come to maturity in the United States, the tar acids will find ready markets in the production of the millions of pounds of phenol-formaldehyde condensation products made here annually, and in the manufacture of synthetic tannins and other products of the dye and fine-chemical industries.

Finally, in many instances, a central distillation plant cannot absorb the output of tar from certain districts, and in other cases transport charges render the disposal of crude tar almost unprofitable. In these cases, distillation by the producer provides a happy alternative and one which is far more remunerative than that of disposing of the crude tar for fuel purposes.

Recent Chemical & Metallurgical Patents

Manufacture of Phosphorus—In the following patent assigned to the Ferro Chemicals, Inc., of Washington, R. Franchot and K. P. McElroy, of Washington, claim that phosphate rock may be reduced to produce phosphorus if it is heated in the presence of carbon and silica. The high temperature necessary to produce this change, which is carried out in a shaft furnace, is achieved with producer gas. The high temperature is esential to insure the fluidity of the calcium silicate slags. The effluent gases contain both

American Patents Issued Feb. 20, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem & Met* readers. They will be studied later by *Chem & Met*'s staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,445,621—Process for Vulcanizing Rubber and Products Obtained Thereby. Sidney M. Cadwell, Leonia, N. J., assignor to the Naugatuck Chemical Co., Connecticut.

1,445,637—Converting Aromatic Halogen Substitution Products Into Amines. Isador Miller, New York City, assignor to William M. Grosvenor, New York City.

1,445,644—Material for the Production of Carbide. James H Reid, Pittsburgh, Pa., assignor to International Nitrogen Co., Cleveland, Ohio.

1,445,645—Process of and Material for the Production of Metal Hydrates and for the Production of Gas. James Henry Reid, Readsboro, Vt, assignor to Thomas Q. Hogan, Boston, Mass.

1,445,660—Process for the Extraction of Vanadium and Radium From Carnotite Ores. Warren F. Bleecker, Boulder, Colo, assignor to the Tungsten Products Co., Boulder, Colo.

1,445,685—Organic Arsenic Compound. Johann Huismann and Jürgen Callsen, Leverkusen, near Cologne, and Wilhelm Grüttefien, Elberfeld, Germany, assignors to Farben-Fabriken vorm. Friedr. Bayer & Co., Leverkusen, Germany.

1,445,735—Method of Producing Coke. James G. West, Pittsburgh, Pa.

1,445,919—Treatment of Aluminum-Hydrate Sludge. Charles W Souder, East St. Louis, Ill. assignor to Aluminum Co. of America, Pittsburgh, Pa.

1,445,935—Agitator. Arthur C. Daman, Denver, Colo., and Thomas J. Pennington, Naugatuck, Conn.

1,445,943—Method of Treating Metallurgical Products. William A. Harty, Buffalo, N. Y., and Frank W. Moore, Thorold, Ont.

1,445,954—Production of Smokeless Fuels and Coke. Stewart Roy Illingworth, Brynfedwen, Radyr, Wales.

1,445,973—Oxygenated Blast for Metallurgical Furnaces. Montague H. Roberts, Jersey City, N. J., and Claude C. Van Nuys, New York, N. Y., assignors to Air Reduction Co., Inc., New York.

1,445,989—Concentration of Minerals. Walter O Borcherdt, Austinville, Va., assignor to the New Jersey Zinc Co., New York.

1,446,012—Process of Preparing Oxalic Acid. George Kolsky, Mamaroneck, N. Y.

1,446,160—Soluble Arsenic Compound and Process of Making the Same. Joseph F. Cullen, Midvale, Utah, assignor to United States Smelting, Refining & Mining Co.

1,446,163—Manufacture of Oxy Derivatives of Anthraquinone. Arthur Hugh Davies, Carlisle, England, assignor to Scottish Dyes, Limited, Carlisle, Cumberland, England.

1,446,185—Process for the Production of Potassium Sulphate. Camille Horst, Wittelsheim, France.

1,446,216—Diamino-Dioxyarsenobenzene-Silver Oxide Compound and Process of Making Same. Alfred E. Sherndal, New York, assignor to Herman A. Metz, New York.

1,446,301—Manufacture of Threads, Filaments and the Like of Cellulose. Horace James Hegan, Coventry, England, assignor to Courtauldo, Ltd., London, England.

1,446,307—Process for the Recovery of Sulphur, Metallic Sulphides and the Like From a Condition of Emulsion Without Filtration on Evaporation. Bertram Hunt, London, England.

1,446,375—Concentration of Oxidized Ores Walter O Borcherdt, Austinville, Va., assignor to the New Jersey Zinc Co., New York.

1,446,377—Treatment of Concentrates. Walter O. Borcherdt, Austinville, Va., assignor to the New Jersey Zinc Co., New York.

1,446,378—Filtration of Ore Pulps. Walter O. Borcherdt, of Austinville, Va., assignor to the New Jersey Zinc Co., New York.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

phosphorus and potassium, and the potassium compounds separate out first, after which the gases are still further cooled so that the phosphorus precipitates. The final effluent is filtered through charcoal to remove the last traces of phosphorus, after which the coke or charcoal containing these traces of phosphorus is returned to the furnace. (1,441,573. Jan. 9, 1923.)

Artificial Silk From Nitrocellulose—Emile Bindschedler, of Switzerland, and George Juer, of Hopewell, Va., have assigned the following process to the Tubize Artificial Silk Co. of America. It consists essentially in treating nitrocellulose with ethyl alcohol in order to remove the water from the nitrocellulose. The dried product is then treated with acetone or one of its homologs. The resulting acetone collodion is spun into filaments by forcing it through spinnerets, and the resulting product is dried by passing warm partly dried air over it. This process, by using dry nitrocellulose and dry acetone, avoids the detrimental effect noted in other cases, and produces a lustrous silk. The acetone is recovered from the air and from the drier by means of benzene and petroleum and certain acids. (1,441,203, 1,441,204 and 1,441,205. Jan. 9, 1923.)

Recovery of Nitrogen-Oxide Vapors—P. A. Guye of Switzerland and Albert Schmidt of France have assigned the following patent to L'Azote Francais of Paris. Apparently aluminum oxide if perfectly anhydrous has an affinity for nitrous vapors. This affinity increases as the temperature at which alumina is dehydrated decreases. The patent is, however, applicable to dry gases only and must be carried out at low temperatures in order to obtain the highest absorption efficiency. (1,443,220. Jan. 23, 1923.)

Process for Treating Air—Arthur B. Lamb, of Washington, D. C., has developed a method of treating air in order to free it from suspended matter of all kinds, such as dust, smoke, pollens, bacteria, etc., and in addition to remove minute particles of such materials as saliva, respiratory excreta and other germ-laden and disease-producing particles. The general principle of the machine is that of an electric precipitator, and the particles are removed by being subjected to a strong electric potential during passage of air through the apparatus. Sterile air can thus be produced for therapeutic purposes, as, for example, in hospitals, etc. (1,442,619. Jan. 16, 1923.)

Non-Corrosive Refrigerating Solution—N. A. Dubois, of Needham, Mass., has discovered a remedy for the extremely corrosive action of refrigerating solutions such as calcium chloride on refrigerating pipes, automobile radiators and other metallic substances. Calcium chloride is often used because of its high solubility in water, even at very low temperatures, but even cast-iron pipes are corroded to a very great extent. The addition of one-tenth of 1 per cent of the weight of the solution of a difficultly soluble chromate, such as zinc chromate, apparently prevents any corrosive action on the part of the solution. This is a rather surprising result, but seems to have been confirmed in a parallel laboratory experiment. (1,442,330. Jan. 16, 1923.)

Preparation of Dry Granular Calcium Acid Phosphate—C. T. Whittier, of Jersey City, has assigned the following patent to the Royal Baking Powder Co., of New York. It deals with new methods of preparing calcium acid phosphate in any desired size of particle. The present method has consisted of grinding the material as it was produced. The new method automatically produces grains of the size desired. Calcium phosphate is treated with sulphuric acid, and the calcium sulphate impurity is filtered off. This leaves a solution of monocalcium phosphate in a more or less free phosphoric acid in solution. Previously this solution was evaporated until the mass on cooling was semi-solid. Then the free phosphoric acid was neutralized in a suitable kneading apparatus. The present system neutralizes the solution of monocalcium phosphate and sprays the dilute solution into a chamber containing hot air or heated water gas. By controlling the density of the solution and the speed of spraying, particles of almost any size can be obtained as desired. (1,442,318. Jan. 16, 1923.)

Saline Solutions Free From Colloidal Silica—G. A. Blanc, of Rome, Italy, has patented a process for obtaining clear saline solutions free from colloidal silica. When many minerals, silicates and silica-containing minerals are treated with acid in order to obtain part of their constituents as soluble salt, one great difficulty lies in the fact that colloidal silica is formed and comes through into the solution, making this distinctly cloudy. The process of avoiding this consists in pouring the acid solution through a layer of the silicate rock from which the soluble materials are to be extracted in such a way as to produce no stirring whatever in the bed. The colloidal silica then replaces the soluble materials of the rock and will not clog up the granular bed in any way unless there is a mechanical disturbance. The solution may then be returned to extract further soluble material. If the layer of colloidal silica which attaches itself to the granular particles is disturbed in any way, the filter bed becomes so dense that no further filtration can be effected. (1,443,674. Jan. 30, 1923.)

Rubber Composition—Philip Schidrowitz, of London, has developed a process for producing a solution of vulcanized rubber. Previously solutions have been prepared from rubber which has been coagulated, dried and masticated. This rubber may be dissolved in naphtha, benzine or like solvents, and may be then vulcanized by heating the solution in the presence of sulphur. This process possesses the advantage of providing vulcanized rubber solution, which could not otherwise be obtained, as vulcanized rubber is relatively insoluble. On the other hand, it is a difficult operation to carry out, and the solvents used are expensive. The present process uses uncoagulated or rubber latex, properly preserved by means of ammonia or other preservatives. The ingredients and fillers may be added and vulcanization takes place in solutions. In this way a very much cheaper solution of vulcanized rubber can be obtained and may be used for impregnating cloth, muslin and other materials. (1,443,149. Jan. 23, 1923.)

The Recovery of Solids From White Water "in Paper Manufacturing"—L. M. Booth, of Plainfield, N. J., has developed a process of coagulating the solid materials in the so-called "white waters" which pass through the screen of the paper machine and settle so slowly that a great percentage of them is lost. The combination of coagulants which has been used up to the present time is sulphate of aluminum and sodium carbonate, in a ratio substantially 2 to 1. These materials are added as a white powder and coagulate the solid particles to such an extent that they may be collected for re-use in paper work. (1,443,454. Jan. 30, 1923.)

Method of Producing Carbonates of the Alkaline Earth Metals—J. H. MacMahon, of Saltville, Va., has assigned to the Mathieson Alkali Works, Inc., of Virginia, a patent whereby sulphides of alkaline earth metals may be transformed into carbonates and the byproducts satisfactorily utilized. For example, black ash from barium converters is leached in the usual manner and the clear solution of barium sulphide is treated with ammonium carbonate preferably obtained by heating the liquor coming from the bicarbonate filters of the ammonia soda process. Barium carbonate and ammonium sulphide result from this reaction, barium carbonate being filtered and washed on appropriate presses or suction filters. Ammonium sulphide in the filtrate is then treated with caustic alkalis sufficient to form the alkali sulphides and free ammonia is obtained, which is then utilized in the ammonia soda process or in some other way. (1,444,623. Feb. 6, 1923.)

Permanent Colloidal Solutions L. Lilienfeld, of Podhajce, Poland, has patented the use of alkyl and aralkylethers of cellulose, starches, dextrin and the like as protective colloids. Other colloid protectors used in salve and ointment are somewhat faulty because of a property described as brittleness which they impart to the resulting ointment. This new class of bodies seem to have no such properties and the ointments are protected from bacteria infections as well. (1,444,257. Feb. 6, 1923.)

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Purifying Graphite—Natural graphite is purified from deleterious admixtures such as silica, alumina, pyrites, mica, etc., by mixing intimately with pulverized coal, charcoal or coke, and heating electrically in a retort to 2,200 deg. C. or over. The proportion of coal required is calculated on that of the impurities present so that the coal will be sufficient to unite with all the oxygen and metallic ingredients. Aluminum, iron, silicon and sulphur are in turn volatilized and may be collected in the form of their oxides in separate receptacles opened for the purpose. The silica is useful as a filtering substance, a polishing powder, etc., the sulphur dioxide for the manufacture of sulphuric acid and the metallic oxides for metallurgical purposes. (Br. Pat. 187,080. M. Langheinrich, Munich. Dec. 6, 1922.)

Lead Salts—Ores containing lead, preferably containing or with addition of oxidizable sulphur, are treated in the presence of dissolved chlorides with chlorine or hypochlorates at a low temperature until the lead is converted into tetrachloride and dissolved. Silver chloride remains with the residue and may be extracted with thiosulphate. The solution is separated and the surplus chlorine is blown out or reduced by reducing agents to obtain lead chloride or sulphate, or the solution is neutralized or rendered alkaline to obtain the lead as peroxide. After the separation of the lead the copper may be removed by cementation or electrolytically and the zinc electrolytically or by precipitation as hydroxide with lime. Arsenic may be precipitated previous to the separation of the copper, by oxidizing (if the solution has been reduced) to convert the iron into the ferric state and neutralizing—for instance, with a carbonate such as limestone or roasted copper pyrites or both. Carbonate ores may also be leached with the acid liquor to neutralize the liquor and extract ingredients from the ores. The reducing agents mentioned are wastes containing zinc or iron, oxidizable salts such as ferrous salts, sulphurous acid or its salts, sulphuretted hydrogen, sulphides, thiosulphates, or organic reducing agents such as sulphite cellulose waste liquor. When sulphurous acid is used the lead is precipitated as sulphate. (Br. Pat. 187,195; not yet accepted. A. Nathansohn, Berlin. Dec. 6, 1922.)

Casein Glue—A composition suitable for use as a glue, paint vehicle, binding agent for asbestos cement sheet, lagging compositions, paper pulp, fiber, etc., consists of casein, sodium silicate, sodium tungstate and camphor solution with or without calcium hydrate. The camphor solution is made by digesting 1 lb. of camphor in 10 lb. of spirits of wine and diluting with ether. This solution is sprayed over the casein and the solvent evaporated. The sodium tungstate is mixed with the casein, sodium silicate is added and the whole is rolled and kneaded until a powder results. This is dried and ground more finely, and the calcium hydrate added, and packed in air-tight containers. Water is added, preferably seven hours before use. Suitable proportions are casein 70 per cent, sodium silicate 27.7 per cent, camphor 0.1 per cent, sodium tungstate 0.25 per cent, and calcium hydrate about 2 per cent. (Br. Pat. 187,200. New Zealand Co-operative Dairy Co., Ltd., Auckland, New Zealand. Dec. 6, 1922.)

Lead Sulphate—The invention is related to the process described in specification 5299/15, wherein sulphate, sulphite and oxide of lead are obtained directly from the native sulphide by volatilizing the latter in an electric furnace. The present invention aims at the production of a product free from sulphite, oxide or unchanged sulphide. Figs. 1 and 2 show, in plan and elevation respectively, the apparatus employed. The finely crushed ore, which may have been previously concentrated, falls in regulated quantities from a

FIG. 1.

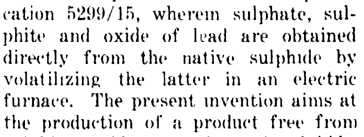

FIG. 2.

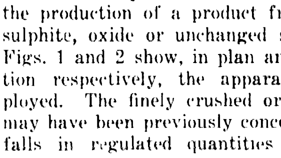


feeding apparatus through the guide tubes 7 on to the electrodes of the furnace. There are arranged in pairs 1, 1, 2, 2, etc., as shown, and are placed about 9 in. above the floor of the furnace 5. About 5 ft. above the arcs is an atmospheric intake 11 communicating through a bifurcated flue 12 with a chamber 13. A fan 14 induces a current of air over the furnace shaft 5, and the fan chambers 13 deliver into spray boxes 14″ wherein the fumes are subjected to the action of water sprays delivered from the perforated pipe 15. A chimney 16 assists the flow of air and fumes through the apparatus. The water containing the reaction products passes through launders 17 into vats 18, where it may be warmed and agitated by steam pipes 20 placed on the floor of each vat. The finely crushed sulphide falls onto the arcs and is at once volatilized. The vapors rise up the furnace shaft into the current of air passing through the top of the furnace and are there oxidized. The reaction products, having been delivered into the vats 18, are agitated, and free acid may be added, if necessary, to convert any sulphites or oxides present into sulphates. The agitation serves to float any sulphide that may have escaped volatilization. This is skimmed off, dried and re-treated. The remaining liquor is neutalized with lime water, and the sulphates finally allowed to settle, decanted and dried for use as a pigment. (Br. Pat. 189,160. J. Gitsham and H. R. Evershed, Launceston, Tasmania. Jan. 17, 1923.)

Water Softening—A reagent for softening feedwater and preventing and removing incrustation in boilers is obtained by saturating a solution of sodium carbonate at a temperature of 5 to 10 deg. C. with aluminate and hydrate of barium and adding extract of tannin. (Br. Pat. 187,647. L. F. C. M. van Weddingen, Gand, Belgium. Dec. 20, 1922.)

Inks and Paints—In a process for making ink, watercolor paints and like compositions, an insoluble base is subjected to high-speed intensive mechanical disintegration with water to form a colloidal solution, to which is added, during disintegration or not, a relatively small quantity of organic dye. The base used may be clay or zirconia, which, being opaque and in colloid form, absorbs the dye to form a product of high coloring power. The base is treated with water in a colloid mill such as described in specification 155,836 and then, after settling, is again treated in the mill with a soluble organic dye in the presence of a protective colloid—for example, gum arabic—to counteract the precipitating action of electrolytes in the water, and, if copying ink is being prepared, glycol, glycerine or the like may be added. A small quantity of disinfectant may be added to prevent decomposition of the protective colloids. After standing for a time, the ink is bottled. Instead of a colorless base, colored insoluble substances such as ultramarine or lakes may be used in the colloidal state with a correspondingly less amount of dye. For india ink or watercolor paints, colloids such as cherrytree gum may be added, and colloidal clay or colloidal carbon used as the mineral base. If tannate or gallate of iron is used as the soluble ink base, an aniline dye is added to give the desired color until the iron salt is oxidized. (Br. Pat. 187,732. Plauson's, Ltd., London. Dec. 20, 1922.)

Motor Fuel—A homogeneous mixture of alcohol and benzol, petrol or other usual liquid hydrocarbon fuel is obtained by dehydrating the alcohol before or after mixing—for example, by the addition of calcium, calcium carbide or other substance that reacts with water and forms an insoluble product, or of an absorbent such as anhydrous lime, ferrous sulphate or potassium carbonate, or by passing alcohol vapor through a column of dehydrating material as when the alcohol is manufactured. (Br. Pat. 188,336; not yet accepted. P. Loriette, Paris. Dec. 29, 1922.)

Sodium Salts—Sodium bicarbonate associated with a small quantity of other soluble salts is extracted from bicarbonated mineral waters by a three-stage process consisting in heating to at least 80 deg. C. in order to remove carbon dioxide and separating the calcium

carbonate precipitated, concentrating, and finally precipitating sodium bicarbonate by passing carbon dioxide, preferably under pressure. The mother liquor adhering to the crystals after their removal contains soluble salts other than the bicarbonate. The carbon dioxide evolved in the first operation may be utilized in the subsequent step of carbonating the liquor. (Br. Pat. 188,335; not yet accepted. Appareils et Evaporateurs Kestner, Lille. Dec. 29, 1922.)

Book Reviews

CHEMISCH - TECHNISCHE UNTERSUCHUNGS METHODEN Vol. I, 7th edition, 1099 pp illustrated Julius Springer, Berlin, 1921

Eleven years have elapsed since the appearance of the sixth edition of this work, which is still issued under the names Lunge-Berl, although the former had no part in the production of this edition. This lapse of time has necessitated a complete rewriting of the work, in which, however, the old principles have been adhered to, in that where the subject matter concerns a given industry, first the raw materials, then the intermediate products and the process control methods, and finally the finished products are taken up and their methods of testing described.

The arrangement of the book is much the same as in earlier editions, including a general section, where such operations as sampling; preparation of samples; weighing, precipitation, drying, etc.; gravimetric analysis; volumetric analysis in all its branches; gas analysis; areometry; manometry and anemometry; measurement of heat by thermometer and pyrometer; colorimetry, and calculation of analytical results are taken up in great detail. A special section includes chapters on technical gas analysis, microchemical methods, electroanalysis, analysis of solid and liquid fuels, boiler water and technical water analysis, drinking water analysis, waste water analysis and air and its testing for various traces of impurities. Further chapters in this special section take up the manufacture of the following products with the analytical methods used therein: sulphur dioxide; nitric acid from Chilean nitrate, from the air by direct synthesis and by oxidation of ammonia; sulphuric acid by the chamber and contact processes; chlorsulphonic acid; mixed and waste acids; hydrofluoric acid; sulphate and hydrochloric acid; soda, including electrolytic caustic soda; chlorine; compressed and liquefied gases; potash salts, including bromine. In this list the following subjects are new, never having been treated in the earlier editions: electroanalysis; microchemical methods; liquid fuels and brown coal tar.

The various sections have been written by experts in their respective lines, many well-known names appearing among the contributors. To some extent this has resulted in overlapping and in a few cases in contradictory statements, though the careful editing, whose earmarks appear throughout the book, has done much to prevent this.

The typographical work and the proofreading are flawless. The profuse illustrations (291), for the most part clean line drawings, make clear the descriptions of apparatus the construction of which it might otherwise be difficult to duplicate. The paper is excellent, being of the old grade which characterized the better German books before the war.

Important tables likely to be used frequently for reference in analytical work have been reprinted on only one side of sheets which accompany the book. These can be mounted and used in the laboratory.

The book is excellent in every particular and is one no research laboratory can afford to be without. If it were available in English it would be an exceedingly valuable adjunct in works laboratories as well. It is to be hoped that a translation is in preparation.

F. C. ZEISBERG.

STANDARD METHODS OF CHEMICAL ANALYSIS A Manual of Analytical Methods and General Reference for the Analytical Chemist and for the Advanced Student. Edited by *Wilfred W. Scott* M.A., in collaboration with thirty-six well-known analytical chemists. Third Edition. Two volumes. D. Van Nostrand Co., 8 Warren St., New York, 1922. Price $10 net.

The division of this edition into two volumes was made advisable by the addition of chapters on asphalts, sampling, soap, selenium and tellurium, sanitary water, molybdenum and tungsten, conversion tables, radium, rubber, solubility of substances and exposives.

Vol. I consists of three parts. Part 1 contains forty-five chapters on the analytical methods for the elements from aluminum to zirconium. Under each element, as in previous editions, the material is grouped under the headings: Physical Properties, Detection, Estimation, Preparation and Solution of the Samples, Separations, and Methods. The attempt is made to present the subjects with sufficient detail to enable one with an elementary knowledge of analytical processes to follow the directions; while long expositions, theoretical discussions and experimental data are purposely avoided. On the whole, the authors have succeeded in this attempt. In places they have been perhaps a little too brief. The analyst whose previous experience did not include considerable work on this determination would certainly have plenty of trouble following the directions for the determination of carbon in organic substances as given on page 119.

While there are naturally omissions of certain methods which one examining the book might want to see included, on the other hand much material is given here that is not readily available elsewhere. When everything is considered, this part is very well done.

Part 2 consists of six pages of qualitative tests given in tabular form and useful only in refreshing one's memory.

Part 3 presents tables and useful data and includes the usual specific gravity and conversion factor tables. In addition, on pages 710-12 there are given a great many weight, volume and energy conversion factors, which heretofore have been either wanting or scattered in various reference books.

Vol. II deals mainly with the analysis of special materials. It includes acidimetry and alkalimetry, alloys, oils, soaps, paints, cement, coal, gas, asphalts, rubber, explosives, water, standard methods of sampling and the determination of solubility. These topics are treated by men who are specialists and in general the treatments are excellent.

There are a few minor criticisms. On page 1007 we are told that "25 cc. of N/1 H_2SO_4 should contain 1.226075 grams" but the error of the burette in which it is measured is probably not less than 1 in 1,000. On page 1089, under Manganese Bronze, no method for aluminum is given, although manganese bronze often contains this element instead of manganese. Under specific gravity of oil on page 1111 the method which uses a plummet with an analytical balance might well have been included. Under coal sampling, on page 1216, the taking of a gross sample of 200 lb. for deliveries up to 100 tons is questionable practice even for small-size anthracite and certainly could not be defended for large sizes of coal. On page 1435, in the soap hardness table, the hardness for 3.5 cc. of soap solution should be 39.0 instead of 38.0. This is an error which should be obvious, but which has been carried from the original A.P.H.A. methods to several other texts.

In regard to the work as a whole, when one considers the labor of assembling and editing the mass of material here presented, he can only wonder that it has been done so well. The paper and print are good and the numerous illustrations are both well drawn and clearly described. This edition is an improvement on its popular predecessors and a valuable addition to any chemist's library.

JEROME J. MORGAN.

LOW-TEMPERATURE CARBONIZATION. Report of the Fuel Research Board for years 1920 and 1921 of the British Department of Scientific and Industrial Research. Available from His Majesty's Stationery Office, Imperial House, Kingsway, London, W. C. 2 for 2s. 3d., postpaid.

This report is a résumé of the low-temperature carbonization situation in England and a report on some extended experimental research which has been in progress for several years under the Fuel Research Board. Any investigator working in this field will find the discussion and the data presented very profitable reading.

As all of the cost data are based upon English conditions, this type of information is not readily convertible to American conditions, but the data regarding yields and the observations on the effect of retort conditions upon coke structure are of great value.

R. S. MCBRIDE.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

No Action on Reparation Dyes as Congress Quits

Adjourns Without Clearing Up Tangle—Textile Alliance Will Soon Be Liquidated—Proceeds to Go to Education

CONGRESS has adjourned without having taken action in the matter of reparation dyes. Apparently the State Department was not prepared to recommend the form the legislation should take. The profits of the Textile Alliance are understood to have been about $1,500,000. Under the agreement with the State Department, three-fourths of that sum is to be converted into the Treasury of the United States The State Department agreed to recommend to Congress that the money be appropriated for educational and scientific work of interest to the textile and chemical industries. The remaining one-fourth is to be expended by the Textile Alliance itself for similar purposes, but in the manner it shall dictate.

When the affairs of the Textile Alliance are wound up, it is expected that approximately $1,000,000 will be turned over to the United States Treasury. At that time the State Department is expected to make its recommendation for the disposal of the money. The National Research Council has recommended that this fund be placed at the disposal of an organization to be known as the American Textile Institute, to be formed to conduct research work in behalf of the textile industry as a whole.

Ruhr Affects Situation

The entry of France into the Ruhr and the refusal of Germany to pay reparations in kind befogged the situation to such an extent that the State Department apparently did not regard the time opportune for legislation intended to prescribe a definite policy for the handling of reparation dyes and for their disposal in this country.

In that connection it may be pointed out that the German statement that delivery of dyes on reparation account would be withheld from France and Belgium cannot be taken seriously, since Germany does not handle the distribution of reparation dyes. She is required to deliver 25 per cent of her daily production to the Reparation Commission, which is charged with their allotment.

A significant feature of the situation is the resignation of Frederick S. Dickson as the advisor of the State Department on the subject of reparation dyes. Previously Mr. Dickson, as chief of the War Trade Board section of the Department of State and prior to that as the officer in charge of the dye and chemical control section of the Treasury Department, administered the import control over dyes and chemicals until that control was superseded by the new tariff act, which went into effect Sept. 22. Mr. Dickson expects to enter private employment, but is not yet ready to discuss the connection he probably will make.

Calendar

The following important technical meetings are scheduled for the immediate future

AMERICAN CHEMICAL SOCIETY
New Haven, Conn., April 3-7

AMERICAN FOUNDRYMEN'S ASSOCIATION
Cleveland, O., April 28-May 1

AMERICAN OIL CHEMISTS' SOCIETY
Hot Springs, Ark., April 30-May 1

SOCIETY OF INDUSTRIAL ENGINEERS
Cincinnati, O., April 18-20

AMERICAN CHEMICAL SOCIETY
New York, Nichols Medal Award, March 9

SOCIETY OF CHEMICAL INDUSTRY
New York regular meeting, March 23

SOCIETY OF CHEMICAL INDUSTRY
New York, joint meeting with other societies, April 20

Double Duties Hamper Trade With Ruhr

With the establishment of strict customs control around the Ruhr district by the occupying French and Belgian forces, shipments for American account in and out of this area are liable to fresh delays.

The French authorities have embargoed the principal products of the Ruhr to prevent their shipment into unoccupied territory. Upon goods leaving the country, not subject to this embargo, the French levy the regular export duties. The German Government, not recognizing the authority of the French to do this, also collects the regular tax. As a result, in addition to the difficulties of transportation to and from the Ruhr district, a new impediment is added to trade with occupied Germany.

U. S. Agriculturists Push Calcium Arsenate

Despite High Price Experts Urge Growers to Continue Use of Poison—Increased Supply Predicted

Cotton growers are justified in paying as much per pound for calcium arsenate as they receive for lint cotton. This view is held by many government specialists who are anxious that the use of calcium arsenate be continued despite the high prices. They contend it has been demonstrated that the use of this poison results in saving sufficiently great to permit its use even at higher prices than now prevail.

Arrangements have been made by the Department of Agriculture with the Air Service of the Army for the use of planes for further experiments in the application of calcium arsenate from the air. As this is written, it seems probable that Congress will approve an additional appropriation of $60,000 to be used specifically for these airplane experiments. One of the great advantages in this mode of application is that all cotton over a large area can be dusted with the poison.

Arsenate Doubles Cotton Yield

In an address on the floor of the House of Representatives, Representative Wilson of Louisiana cited concrete instances where the yield of cotton had been doubled by the use of calcium arsenate. He pointed out that the boll weevil has been responsible during recent years for an average loss of six million bales of cotton annually. When to the value of that cotton is added the losses occasioned to allied industries, the total is brought to staggering proportions, he declared.

In view of the world-wide increase in the demand for cotton, a special effort is being made by government specialists and by members of Congress from the cotton-growing states to encourage the wider use of calcium arsenate despite the high price. They recognize that the quickest way to bring production abreast with demand is to pay a price which will encourage output. At the same time the Federal Trade Commission and the Department of Justice are being relied upon to discover any effort to take advantage of the existing situation to manipulate prices.

These two government agencies are paying particular attention to the spread between the prices paid producers and those charged the ultimate consumer.

Final Dye Rules Issued by Treasury Department

Regulations for the Entry and Appraisement of Dyes Under Tariff of 1922 Officially Issued on March 2

THE regulations for the entry and appraisal of dyes and coal-tar products in accordance with paragraphs 27 and 28 of the 1922 tariff, have been officially issued by the Treasury Department under date of March 2, 1923. The rules follow:

Regulation 1. Taking Samples Prior to Entry.—An importer may be permitted under proper supervision to take samples from his own importations prior to entry of articles dutiable under paragraphs 27 and 28, and appraising officers may take samples of such articles prior to entry when deemed necessary by them.

Regulation 2. Information Required Prior to Entry.—When an importer seeks information from the appraising officer prior to entry or for the importer's convenience formal entry is withheld as herein after provided, in return therefor the importer shall furnish to the appraising officer such relevant information as he may request.

Regulation 3. Determination of Similar Competitive Articles.—(*a*) A domestic article shall be considered a similar competitive article if in the use or uses which require a major portion of the total consumption in the United States of the imported and the domestic article the imported article accomplishes results substantially equal to those accomplished by the domestic article when used in substantially the same manner.

(*b*) An imported article which is or may be used for the same purpose as a domestic article not freely offered for sale but used in the manufacture of another domestic article freely offered for sale shall be considered a similar competitive article.

Regulation 4. Lists of Competitive and Non-Competitive Article.—(*a*) The Appraiser at New York shall issue at once lists of articles which he believes to be competitive and non-competitive and shall from time to time add articles thereto or remove articles therefrom as investigation shall justify. Such lists shall be advisory only and at the top of each list shall appear the following statement:

> This list is advisory only and in no manner relieves appraising officers from the duty of independent appraisement required by law.

The appraiser shall furnish copies of such lists and amendments thereof to the Customs Information Exchange for circularization to other appraising officers and to the public upon request.

(*b*) In the case of an actual importation of a similar competitive article the appraising officer may furnish to the importer upon application in writing informaton of the American selling price, provided the appraising officer shall be satisfied that the importer after exercising due diligence has not himself been able to obtain such information and that he has submitted to the appraising officer all relevant information in his possession. All information furnished by the appraising officer shall be advisory only. In communicating such American selling price, however, the appraising officer shall not disclose the source of his information.

(*c*) In the case of non-competitive articles appraising officers shall not advise importers prior to entry concerning values.

Regulation 5. Entry of Articles on Neither the Competitive Nor the Non-Competitive List.—The Appraiser at New York upon application of an importer having an invoice of an article not named on either the competitive or the non-competitive list shall proceed immediately to ascertain to which list the article belongs, and upon such ascertainment shall add the article to such list, pending which the importer may withhold formal entry. The appraiser shall inform the importer of his action.

Regulation 6. Difference in Strength of Imported and Domestic Articles.—When an imported article is of different strength from a similar competitive article manufactured or produced in the United States, the value of the imported article shall be adjusted in relation to the selling price of the domestic article in the proportion which the strength of the imported article bears to that of the domestic.

Regulation 7. Determination of American Selling Price of Articles Not Freely Offered for Sale but Used in the Manufacture of Other Articles.—When an article is a similar competitive article as defined in Regulation 3(*b*), the value of the imported article shall be the American selling price of the domestic article freely offered for sale adjusted in the relation that it bears to the domestic article not freely offered for sale.

Regulation 8. Ascertainment of American Selling Price When an Article Is Offered for Sale at Arbitrary Prices.—When the appraising officer shall be satisfied after investigation that a similar competitive domestic article is offered for sale at an arbitrary and unreasonable price not intended to secure *bona fide* sales and which does not secure *bona fide* sales, such price shall not be considered as the American selling price, and such officer shall use all reasonable ways and means to ascertain the price that the manufacturer, producer or owner would have received, within the meaning of Section 402(*f*) of the tariff act of 1922.

Regulation 9. Where There Are Two or More Similar Competitive Domestic Articles.—Where two or more domestic articles are considered similar competitive articles compared with an imported article, the American selling price of the domestic article which accomplishes results most nearly equal to those of the imported article shall be taken as the basis for the assessment of the ad valorem rate.

Regulation 10. Articles Which Are Not Coal-Tar Products.—The words "similar competitive articles" in paragraphs 27 and 28 shall not be construed as relating exclusively to coal-tar products. An imported coal-tar product may be compared with a domestic non-coal-tar product, or an imported non-coal-tar product dutiable under paragraph 27 or 28 with a domestic coal-tar product, for the purpose of determining whether they are similar competitive articles. The rule provided in paragraphs 27 and 28 for the determination of similar competitive articles and the regulations herein provided shall be applied in such cases.

Regulation 11. Ascertainment of United States Value.—The following instructions for the ascertainment of United States value are reproduced from Treasury Decision No. 39297 of October 31, 1922.

(T. D. 39297)

United States Value of Imported Merchandise

Appraising officers instructed how to ascertain the United States value of imported merchandise as defined in Title IV, section 402, subdivision (*d*), tariff act of 1922.

Treasury Department,
Oct 31, 1922.

To Appraising Officers.

Attention is invited to the definition in Title IV, Section 402, subdivision (*d*), tariff act of 1922, of the term "the United States value of imported merchandise."

Certain questions having arisen in connection with the application of this definition to imports classifiable under paragraphs 27 and 28 of Title I of the act, the department offers the following concrete example as best illustrating its views on the procedure and computations necessary in arriving at the United States value of such merchandise:

Assume that certain dyes classifiable under paragraph 28 were exported from Germany on Sept. 15, 1922, and imported at New York on Oct. 1, 1922, and that the "such or similar imported merchandise" which subdivision (*d*), section 402, Title IV, contemplates shall be taken as the standard of comparison was selling at New York on Sept 15, 1922, in the usual wholesale quantities, etc., at $1.45 per lb. This price includes the various items for which subdivision (*d*) provides that allowance shall be made. Assume a maximum allowance of 8 per cent for profit; dividing $1.45 by 1.08 gives $1.34 and subtracting this from $1.45 leaves 11 cents as the amount of the profit included in the $1.45. Assume a maximum allowance of 8 per cent for general expenses, dividing $1.34 by 1.08 gives $1.24 and subtracting this from $1.34 leaves 10 cents as the amount of the general expenses, included in the $1.45. Assume that the cost of transportation, insurance and other, necessary expenses from the place of shipment in Germany to New York was 3 cents and deducting this from $1.24 leaves $1.21, which includes the dutiable value and the duty. Assume that such merchandise was an article which on Sept. 15 was dutiable under section 500 of the act of Sept. 8, 1916, at 30 per cent ad valorem. Dividing $1.21 by 1.30 gives $0.93 as the value upon which duty was assessed, and which is the United States value of the merchandise imported on Oct. 1, and subject to the 60 per cent ad valorem rate provided for in the proviso of paragraph 28. When the article is subject to both a specific and ad valorem rate, the specific duty will be deducted before making the division.

The amount to be deducted as duty in each case will be governed by the amount of duty actually paid on the article used as the basis for computation.

The foregoing applies to purchased goods. In the case of consigned goods the appraiser will ascertain the amount of commission paid or contracted to be paid and allow not to exceed 6 per cent of the gross selling price, in lieu of the 8 per cent profit and 8 per cent general expense. The transportation costs and duty will be ascertained in the same manner as on purchased goods.

Appraising officers will ascertain in the usual way through the special agency service or otherwise, as provided by law and regulations the facts necessary to be used in such computations.

EDWARD CLIFFORD,
Assistant Secretary.

Regulation 12. Tests.—Tests which are necessary in the appraisement of imported articles shall be made under conditions approximating as closely as practicable the conditions in which the articles will be actually used in trade or manufacture.

Regulation 13. Trade Papers as Sources of Information.—Appraising officers may consult the trade papers, but the weight to be given to the quotations and other information therein is for the determination of the officers themselves.

Regulation 14. Obtaining Information on Doubtful Questions.—Appraising officers at ports other than New York when in doubt on any question arising under paragraphs 27 and 28 shall take the question up direct with the Appraiser at New York, who shall give his advice as promptly as possible. If the appraising officer shall be dissatisfied with the advice of the Appraiser at New York, or the latter shall be in doubt on the inquiry, the question shall be submitted to the Department for an expression of its views.

EDWARD CLIFFORD,
Assistant Secretary.

Engineers to Have Museum

Mechanical Engineers Accept Smithsonian Offer for Central Unit in Washington—Others Planned

The joint committee recently appointed by the American Society of Mechanical Engineers has decided to accept the offer of the Smithsonian Institution to establish at Washington, D. C., a central historical museum of engineering, in connection with which local branches will be developed in other sections.

The museum will be a storehouse for records of American engineering achievements. It will afford opportunities for research and investigation. The plan has obtained the co-operation of the Federated American Engineering Societies, from which body the joint committee was selected by the A.S.M.E.

The Smithsonian Institution, in offering to act as custodian of collections, urged that the movement be broadened from an engineering society standpoint to that of a national museum. This idea was acceptable to the engineers and the museum will be founded on the broadest possible basis.

Stamford Chemists Hear Prof. Johnston

Points Out Errors in Existing Literature—Says Pressure Chemistry Is Normal Chemistry

At a meeting of the Stamford Chemical Society, Monday evening, Feb. 26, Prof. John Johnston of Yale University gave the principal address on "Some Effects at High Pressure." Dr. Johnston pointed out the unfortunate existence of a great many errors in the literature of the subject. This situation was, of course, not confined to data on high pressures, but was perhaps particularly noticeable there because the preliminary work had been very crude. Nearly 25 years ago it was felt in many quarters that inorganic chemistry had been completed. It was a finished subject. Then Ahbegg began his epoch-making compilations which have resulted in his Handbook on Inorganic Chemistry, now a standard reference work. This served to call attention to many of the gaps in inorganic chemistry. It began to be appreciated that the selection of an arbitrary temperature for inorganic reactions such as 25 deg. C. was somewhat ridiculous; and then a great many investigators began work at high temperatures and a few at high pressures, so that we are beginning to collect data on inorganic compounds with general relation to their critical constants.

Effects of Stress

The speaker further stated that an easy differentiation could be made between the effects of uniform and variable pressure, the latter producing stresses in the material, while the former does not. Stresses have a permanent effect on physical and chemical properties. Uniform pressure, however, causes no ultimate change. The effect of using, as a pressure medium, a substance which has a positive chemical reaction with the material compressed produces very large changes in the result. This is particularly true if calcium carbonate is measured under carbon dioxide pressure. Solubility increases seventy times within the experimental pressure range.

Dr. Johnston took particular pains to point out the fact that pressure chemistry was normal chemistry and that no abnormal effects could be traced to the influence of pressure. The statements in geological books that such and such a peculiar result was probably due to pressure must inevitably be revised, because it can be shown in the laboratory that pressure does not have any effect of that kind. Many costly industrial experiments have been attempted on the theory that pressure would have some unusual effect and many useless patents have been granted on that assumption. One of particular note was mentioned, an attempt to separate cadmium from zinc under pressure, when it could be shown from theoretical research that no such separation could possibly be effected.

New Financing Plan Adopted by A.E.S.C.

A new plan for financing the industrial standardization work of the United States, which provides for membership dues on the basis of one cent per $1,000 of gross receipts, has been formally approved by the executive committee of the American Engineering Standards Committee. And twenty of the most influential industrial executives of the country have accepted places on an advisory committee which will co-operate with the ways and means committee in the refinancing of the American Engineering Standards Committee.

In submitting the report of the ways and means committee, A. W. Whitney, chairman of that committee and of the A.E.S.C., declared that the economies which should accrue to the industries of America, through standardization, "are to be measured in billions of dollars, not millions."

New Class of Members

This report announces a new class of members in the A.E.S.C. to be known as "sustaining members," and provides a special service to "sustaining members," including information bulletins on developments in standardization work in this country and in every other country where industrial standardization is in progress.

The plan calls for the appointment of an engineer-translator who will provide translations of standards developed in foreign countries for the information service to sustaining members. The new information service will be an elaboration of the work which the A.E.S.C. has been carrying on in a small way, in calling to the attention of co-operating bodies and the technical press the important developments in standardization work, foreign as well as American.

Agriculture Department Plans Work for Color Laboratory

A committee of dye chemists has been appointed by the Secretary of Agriculture upon recommendation of W. G. Campbell, acting chief of the Bureau of Chemistry, to formulate plans of work for the Color Laboratory.

The committee consists of R. Norris Shreve, secretary of the Dye Division of the American Chemical Society; Willard H. Watkins of the National Aniline & Chemical Co., Buffalo; Louis A. Olney of Massachusetts, president of the American Association of Textile Chemists and Colorists; Dr. William J. Hale, of Michigan, chairman of the Dye Division of the American Chemical Society, and Dr. Clarence G. Derick, of Buffalo, N. Y.

The laboratory has in its past work felt the need of a more intimate knowledge of the problems of the industry as a whole throughout the country. The function, therefore, of the above-named committee will be to consult frequently with the bureau so that it may be conversant with the needs of various sections and schedule its work accordingly.

American Interests Protest British Rubber Restriction

Firestone Leads Conference Which Urges Repeal of British Law and Seeks U. S. Source of Supply

A campaign for the repeal of the British rubber restriction act and for the development of sources of crude rubber supply that will make America independent of other countries was inaugurated at a conference held last Wednesday in Washington between the automotive industries and government officials. H. S. Firestone, of the Firestone Manufacturing Co., was the leading spirit in the conference and acted as host to the visiting manufacturers. Philip H. Lockhart of the India Rubber Manufacturers' Association of Great Britain addressed the conference. He is vice-president of the Federation of British Industries, which includes 2,200 manufacturing firms and which is opposed to British restriction. He said, in speaking of the English manufacturers' attitude, that they do not like the restriction act in any shape or form. He said he felt sure the three representatives of the Rubber Growers' Association who came from England recently for a tour of the American rubber industries had returned to England with a much better comprehension of the wants of America than ever before.

Resolutions Adopted

Resolutions were passed which authorized Mr. Firestone to appoint a committee to carry on this work. This committee will be announced shortly and will immediately take vigorous steps to achieve the desired ends. Plans are now being worked out for a permanent organization. In speaking of the conference Mr. Firestone said:

> The conference clearly proved that exceptional interest had been aroused over the restrictive measure, and the enthusiasm shown by the manufacturers present indicated that they felt the time was ripe for concerted action looking to the abolition of the law.
>
> Our plans now provide for a permanent organization to carry to a successful conclusion the program designed to induce Great Britain to reconsider her unwise legislation pertaining to rubber, and to promote the development of rubber plantations in the Philippines and South America, as well as in continental United States, which latter field's possibilities were presented by Secretary of Agriculture Wallace
>
> We hope to formulate plans to give every assistance available to the Departments of Commerce and Agriculture in their respective surveys of potential rubber producing regions, realizing that the rubber industry and the general public will benefit in the end.

Ruhr Occupation Hurts East

The Far East is feeling the pinch resulting from the uncertainty as to the delivery of German chemicals more than any other section of the world, in the purview of the Department of Commerce. Prices have advanced sharply, somewhat out of proportion to advances in other countries. Whether this has been occasioned by the low state of stocks or is due to the readiness with which they have been cornered has not been determined.

Southern California A.C.S. Discusses Ceramics

F. B. Ortman Details Progress in Industry and Points Out Problems Needing Solution

At the regular monthly meeting of the Southern California Section of the American Chemical Society, held at Los Angeles on Feb. 15, F. B. Ortman, vice-president of Tropico Potteries, Inc., gave an interesting address on recent developments in the field of ceramics. Mr. Ortman classified the various clay groups to include pottery, faience, heavy clay and refractories. Glass was subdivided into building glass, pressed and blown glass, and optical glass. Enameled metal is an important development of the ceramic industries, accounting for a turnover of over $42,000,000 annually. Sanitary ware is being manufactured in rapidly increasing volume, and abrasives are assuming importance. Mr. Ortman discussed the blending of clays and the steps taken to prevent scumming and efflorescence. Details were given as to the general composition of white ware, and customery burning practice. American and European porcelain were compared.

Developments in Ceramics

An important development in the industry has occurred in connection with drying, known as the humidity method. The humidity principle involves the boxing of the shape in an atmosphere of low temperature and comparatively high humidity for a few hours until heated thoroughly and until a uniform vapor density has been attained. The temperature is then increased rapidly. The result is an absence of case hardening and a considerable economy in time. By the old method, the burning of terra cotta ware would take from 7 to 10 days. By the new method, the operation is completed, more efficiently, in 18 hours.

Mr. Ortman dealt at length with the subject of glazing, and discussed the troubles experienced, due to the difficulty of getting a glaze and body of uniform coefficient of expansion. Dealing with the subject of health regulation, the speaker discussed the use of lead in the ceramic industry. Mr. Ortman then paid a tribute to the leaders in the industry for the manner in which they disseminated information. The bars of secrecy that formerly characterized many operations in ceramics have been let down, and there are no trade secrets. Formulas are only of value in connection with the material and conditions at the factory in which they were developed. Technicians have nothing to lose and a great deal to gain by adopting a frank attitude toward their confrères.

Discussion Held

H. L. Payne, the chairman, at the conclusion of the address called for discussion, mentioning that a recent issue of *Chemical & Metallurgical Engineering*, to which he referred in complimentary terms, had an advertisement for Los Angeles refractories of exceptional qualities. T. S. Curtis, the president of the Vitrefrax Company, replied, and gave some interesting information about the products in question, and the progress being made in the erection of the company's new plant. The exact analysis of this refractory, it was learned, has baffled even the most experienced.

Mark Walker, the secretary of the section, announced that Dr. Franklin, the newly elected president of the society, who is also the president of the Southern California Section, would attend the next meeting, to be held on March 16, and deliver an address on the ammonia compounds, a subject on which he is the undisputed authority. This meeting will constitute the inauguration of a lecture tour which Dr. Franklin will undertake on his way to the Eastern States.

Bureau of Mines Car to Make a 6 Months' Trip

Contrary to the information recently published in these columns, the Bureau of Mines car "Holmes" has not been dismantled, but has started on a 6 months' trip, during which experiments will be conducted at various refractories plants. The experimental work which will be done at each of these plants is in co-operation with the Refractories Manufacturers' Association. The plants at which the experiments will be conducted follow: American Refractories Co., Baltimore; Brooklyn Fire Brick Works, Brooklyn; Lavino Refractories Co., Womelsdorf, Pa.; Kier Fire Brick Co., Salina, Pa.; Ashland Fire Brick Co., Hayward Station, Ky.; Charles Taylor Sons Co., Taylor, Ky.; Chicago Fire Clay & Retort Co., Ottowa, Ill.

Personnel for Trip

E. P. Ogden, a ceramic engineer attached to the Columbus Station of the Bureau of Mines, is immediately in charge of the technical work that will be done at these plants. The car is accompanied by Alfred Whitford, E. M. Rupp and A. H. Fessler, ceramic engineers; R. F. Lunger, fuel engineer; F. Wentzell, laboratory assistant, and W. E. Rice, the car foreman. G. A. Bole, the superintendent of the bureau's Ceramic Station, came to Washington to confer with bureau officials and the men on the car. While the car was in the railroad yards at Washington, it was inspected by a number of public officials.

South Starts Tire Making

A recent report from Birmingham, Ala., tells of the formation of the Murray Tire Co., to manufacture in that city various grades of automobile tires. The interests behind the new concern have long been engaged in marketing tires in the South, and because of the proximity of the source of such raw materials of tire making as cotton and corn they feel they can carry on manufacture there more cheaply than in any other section.

Federal Jury to Investigate Paint Makers

Attorney-General Orders Probe Into Alleged Sherman Law Violations of Paint Association

On instructions from Attorney-General Daugherty, who is investigating charges that the Paint Manufacturers' Association of the United States is violating the Sherman anti-trust law, the federal grand jury of Philadelphia began on Feb. 26 an investigation.

Accordingly Samuel R. Matlack and George B. Heckel, vice-president and secretary of the association, respectively, were called before the jury. Mr. Matlack, who is president of G. D. Wetherill & Co., Inc., denied emphatically the charges made. Mr. Heckel said he knew of no violations of the law by the association. He further stated that the association maintained a bureau in Washington to aid the government in preventing any possible abuses.

Texans Oppose Carbon Black Plants

The establishment and operation of carbon black plants in the Bethany natural gas region of Texas, permitted in a bill now before the Texas Legislature, are strongly opposed by chambers of commerce and other trade and civic organizations in the district. It is held that the operation of carbon black plants will jeopardize the natural gas supply seriously and curtail the chances for other industries to utilize the large deposits of clays, silica sands, ocher, iron ore and other raw materials in this district, as well as make similar curtailment in the supply of gas for domestic service. A carbon black plant, it is set forth, consumes more gas than a city of 25,000 persons each day, close to 100,000,000 cu.ft. of gas daily being utilized by the plants in the Monroe, La., field. It is also pointed out in the protest that such a plant furnishes employment for only a comparatively small number of persons, gives little revenue to the land owner, and is not desirable from a community and industrial viewpoint.

Olive Oil Foots Hearing Is Extended

An extension of time, in the hearing before the Treasury Department in which oil importers seek the imposition of a 10 per cent duty on olive oil foots under the new tariff act, has been granted by Assistant Secretary Clifford.

The tentative plan of the Treasury to assess this commodity has aroused much protest from soap makers. The soap interests, which asserted that the commodity is sulphured oil unfit for food, have presented their case to the department quite fully. The oil importers, who feel the free import of olive oil foots is discrimination against them, were late in presenting their side of the argument and for this reason the time has been extended.

Cotton Men Remove Hutchison

Since his election as president and managing director of the National Campaign for Boll Weevel Control, the American Cotton Association has revoked Dr. M. Reese Hutchison's appointment as managing director of research for that organization.

President J. S. Wannamaker of the American Cotton Association announces that the activities of that body are to be intensified. Plans are under way to form an independent scientific research commission which is to co-operate with state and federal agencies in studying control methods for the boll weevil menace.

Engineering Council Meets

The executive board of the American Engineering Council, which is the governing body of the Federated American Engineering Societies, will meet in Cincinnati March 23 and 24. Government reorganization and reforestration will be among the chief questions to be discussed by the engineers, who will represent thirty national and local engineering societies.

Charles H. MacDowell of Chicago is chairman of the engineering committee which is arranging the plans. Other members are S. H. McCrory, chief of the Division of Agricultural Engineering, U. S. Department of Agriculture; W. H. Hoyt of Duluth, Minn.; and J. C. Ralston of Spokane, Wash.

Assistant Patent Examiners Wanted

The United States Civil Service Commission announces an open competitive examination for assistant examiner, Patent Office, to take place on April 4, 5 and 6, 1923, at various post offices and custom houses throughout the country. Vacancies in the Patent Office at an entrance salary of $1,500 and $20 per month bonus will be filled from the results of this examination.

Those desiring to take the examination should apply immediately to the United States Civil Service Commission, Washington, D. C., for full information, stating the name of the examination which they desire to take and applying for form 1312.

Government Seeks Chemists

The United States Civil Service Commission announces open competitive examinations for the positions of chemist ($3,000 to $5,000 per year), associate chemist ($2,000 to $3,000 per year) and assistant chemist ($1,600 to $2,000 per year). The vacancies to be filled are in the Chemical Warfare Service, Edgewood Arsenal, Md. There are also some positions of similar qualifications.

Applicants can secure full information by writing to the Civil Service Commission at Washington, D. C. Application blanks, Forms 2118 and 2376, can be secured from the following places: Civil Service Commission, Washington, D. C.; the Secretary of the United States Civil Service Board, Custom House, Boston, Mass., New York, N. Y., New Orleans, La., Honolulu, Hawaii; Post Office, Philadelphia, Pa., Atlanta, Ga., Cincinnati, Ohio, Chicago, Ill., St. Paul, Minn., Seattle, Wash., San Francisco, Calif., Denver, Colo.; Old Custom House, St. Louis, Mo.; Administration Building, Balboa Heights, Canal Zone; or the Chairman of the Porto Rican Civil Service Commission, San Juan, P. I.

Applications must be filed with the Civil Service Commission, Washington, D. C., with the material required, prior to closing March 27, 1923.

Chemistry Institute Meets

At the regular meeting of the Council of the American Institute of Chemistry on Feb. 26, new applicants were elected to membership and plans completed for the circularization of American chemists on the desirability of affiliation with this strictly economic society of chemists.

Dr. Frederick D. Crane was appointed chairman of the classification committee, L. R. Seidell of the employment committee and H. G. Byers of the ethics committee. Reports were read announcing the early establishment of chapters and of the growth of interest in the plans of the Institute throughout the country. Chemists interested in the efforts of this organization to establish the professional status of chemists on an economic as distinguished from a scientific basis are urged to send their suggestions to the Council, 381 Fourth Ave., New York.

Imports Statistical Service to Expand

The Department of Commerce is planning to expand its statistical service on chemical imports. This will include the entire synthetic organic group. At present an accurate picture of the volume of many imports cannot be had, due to the lack of subdivision. For the import statistics to be of greatest value, it is necessary in many instances to describe the individual commodities or qualities of a commodity. The House Committee on Appropriations has allowed a deficiency appropriation of $150,000 with which to expand the imports statistical service.

Gas Association Convention Fixed

The American Gas Association will hold its 1923 convention at Atlantic City during the week of Oct. 15. This decision has been reached after a canvass of the entire membership of the association, which resulted in 71 per cent of the votes for Atlantic City. The convention there will be supplemented by an extended exhibition probably on the Steel Pier. In reaching this decision the committee has tentatively recommended that the 1924 convention be held in Chicago.

New Law Establishes Naval Stores Standards

The Senate Committee on Agriculture and Forestry favorably reported a bill to establish standard grades of naval stores, under direction of the Secretary of Agriculture, which was passed in the closing hours of Congress and signed by the President.

The bill as passed is a complete substitute for previous measures on this subject which have been pending before the committee. It embodies the fundamentals agreed upon between the Department of Agriculture and a committee representing producers and large consumers of naval stores.

Three standard grades of turpentine are established, "gum spirits of turpentine," made from gum from a living tree; "steam-distilled wood turpentine," which shall be wood turpentine distilled with steam from the oleoresin within or extracted from the wood; and "destructively distilled wood turpentine," which shall be wood turpentine obtained in the destructive distillation of the wood. Two classes of rosin are established, "gum rosin" and "wood rosin," with thirteen grades.

The Secretary of Agriculture is authorized to change grades or to create new grades after 6 months' notice to the trade. Sale of naval stores not within the standards, or false gradings, would be made punishable by a fine not to exceed $5,000 or imprisonment of not more than a year, or both.

Baby Element Was Expected

Chemists at the Bureau of Mines are inclined to accept the accuracy of the observations resulting in the announcement that a new element had been discovered. This element has been called hafnium, as has already been announced in our columns. Work at the Bureau of Mines has indicated the probability that an element exists which belonged to that point. The element having an atomic number of 72 was missing from the series, and on the periodic table it will come between lutecium, which has an atomic weight of 175, and tantalum, which has an atomic weight of 181.

Paper Exposition Announces Speakers

The Paper Industries Exposition, which is to be held at Grand Central Palace, New York, the week of April 9, has secured as speakers for Printers, Publishers and Advertisers day, Friday, April 13, Don C. Seitz of the New York *World* and Dr. R. E. Rindfusz, secretary American Writing Paper Co.

Mr. Seitz, who is business head of the *World*, will discuss the newsprint situation from the point of view of both manufacturer and consumer, for the *World* owns its own paper mills. Dr. Rindfusz will speak on the "Standardization of Bond and Ledger Papers," a task on which his organization, in co-operation with numerous consumers, has long been working.

Increased Paper Output In Newfoundland

An agreement which will increase the output of the paper mills of the Anglo-Newfoundland Development Co. at Grand Falls, N. F., by 100 tons per day has been arrived at between Lord Rothermere and Sir Richard Squires, representing the Government of Newfoundland. Premier Squires, in announcing the arrangement, said that no concessions were involved and that the deal was a straight business proposition. Work will be commenced on the concessions as soon as possible and, in conjunction with the Sir W. G. Armstrong Whitworth development at Humbermouth, will provide for a total increase in the dominion's paper output of 500 tons per day. When these two developments are completed Newfoundland will manufacture approximately 2,500,000 tons per annum.

Personal

R. V. AGETON, of the Bureau of Mines staff, has gone to Pitcher, Okla., to work with Dr. F. Flynn of the Public Health Service on a study being made of the dust conditions in zinc and lead mines at that point.

Dr. EDGAR C. BAIN has gone to Dunkirk, N. Y., with the Atlas Steel Corporation as research metallurgist. He still maintains contact with the National Lamp Works of the General Electric Co. through the Cleveland Wire Division, in a consulting capacity.

CHARLES A. BLOOMFIELD, head of the Bloomfield Clay Co., Metuchen, N. J., was honored on his seventy-fourth birthday, Feb. 25, by having a large framed portrait hung in the new ceramics building, Rutgers College, New Brunswick, N. J., in recognition of his accomplishments in founding the ceramics department at the institution.

A. E. BUCHANAN, JR., has resigned as assistant editor of *Chem. & Met.* to become assistant secretary of the Alumni Association, Lehigh University, Bethlehem, Pa., which is a newly created position. He was married to Miss Lois Pease on Feb. 22 and expects to assume his new duties early in March, after returning from Bermuda.

JOSEPH R. CARPENTER, a scientific assistant, has been appointed to a position in the Color Laboratory of the Bureau of Chemistry, Washington, D. C., by transfer from the Fixed Nitrogen Research Laboratory of the Department of Agriculture.

NORRIS GOODWIN is now general manager of the International Chemical Products Co., Glendale, Calif.

H. A. GREAVES and H. ETCHELLS have been awarded jointly the certificate of merit of the Franklin Institute, Philadelphia, Pa., for notable and oirginal inventions for their electric steel melting furnaces, known as the "Greaves-Etchells" type furnace.

O. S. KEENER, junior chemist, has been transferred from the Carbohydrate Laboratory, Bureau of Chemistry, Washington, to the St. Louis station. J. L. SULLIVAN, food and drug inspector, has been transferred from St. Louis to Chicago, and Inspector WILLIAM B. TIEDT has been transferred from Chicago to St. Louis.

THOMAS MIDGLEY, JR., will be presented the Nichols Medal on March 9, for his work in the development of the anti-knock compounds for internal combustion engines.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, spoke at Princeton University March 1, on radium.

J. S. NEGRU has left the editorial staff of *Chem. & Met.* to take up engineering practice with special reference to mining engineering. He will also handle industrial diamonds for diamond drilling.

W. O'NEILL, vice-president and general manager of the General Tire & Rubber Co., Akron, Ohio, gave an interesting and instructive address before the members of the Down Town Association at Hotel St. Francis, San Francisco, Calif., on Feb. 15 on the subject "What About the Rubber Industry?"

HAROLD J. PAYNE, a '22 graduate of M.I.T., who has been with the General Electric Co. at Pittsfield, Mass., since his graduation, is now an editorial assistant on the staff of *Chem. & Met.*

ALFRED I. PHILIPPS, formerly associate gas engineer, National Bureau of Standards, and lately service engineer of the American Gas Association, is now gas engineer with Arthur D. Little, Inc., Cambridge, Mass.

T. T. READ, chief of the Information Service of the Bureau of Mines, has returned from a visit to a number of South American countries.

Dr. WALTER ROSENHAIN, the English scientist, gave two brilliant lectures at Carnegie Institute of Technology, Pittsburgh, on Feb. 12 and 13. The subject of his first address was "Metallurgical Research at the National Physical Laboratory, Teddington, England," and the other was on "Strain, and Its Relation to Fractures of Metals."

GEORGE P. SHINGLER, JR., has been appointed as an associate chemist in the Leather and Paper Laboratory of the Bureau of Chemistry, Washington, D. C., by transfer from the Chemical Warfare Service.

F. C. WEBER, chemist in charge of the Animal Physiological Laboratory of the Bureau of Chemistry, resigned at the end of January, to accept a position with the Fleischmann Laboratories, New York City.

Obituary

DAVID AUGUSTUS DECROW, manager of the waterworks department of the Worthington Pump & Machinery Corporation, New York, died in East Orange on Thursday, Feb. 15, and was buried in Lockport, N. Y., Sunday, Feb. 18. He was born in Bangor, Me., and was graduated from Maine State College of Mechanic Arts of the University of Maine at Orono, in the class of 1879.

After his graduation from college, Mr. Decrow taught school for a year or more in a lumber camp in Maine. He went from Maine to Lockport in the early '80s and became associated with the Holly Manufacturing Co. as a mechanical draftsman. In 1893 he was made designing engineer, in 1900 chief engineer and in 1903 secretary of the company. During his connection with that plant he became known as a waterworks engineer and continued his work as a specialist in that line to the time of his death. Some years ago the Holly Manufacturing Co. was combined with the Snow Steam Pump Works at Buffalo, N. Y., as part of the International Steam Pump Co. Mr. Decrow went to Buffalo at the time of this change and took charge of the pumping machinery manufactured by both companies.

The International Steam Pump Co. was succeeded by the Worthington Pump & Machinery Corporation in April, 1916. Soon thereafter Mr. Decrow was called to the head office in New York as manager of the waterworks department and continued in this position until his untimely death. He is survived by his wife and two sons.

JAMES T. HEAD, for many years in charge of the production of potassium cyanide and other products at the local plant of the H. V. Davis Chemical Works, New Bedford, Mass., died Feb. 8, of Bright's disease, at the age of 72.

CHARLES PHILIP MONTO, chemical engineer, died in Kotka, Finland, Feb. 17, 1923. He was connected with the National Carbon Co., Cleveland, Ohio, the Nungesser Carbon & Battery Co. of Cleveland, Ohio, and the Superior Carbon Products Co. of Poughkeepsie. He sailed for Finland in June, 1921, to engage in the manufacture of carbon electrodes and batteries, in which business he was engaged at the time of his death, which occurred from pneumonia. His body is being brought to this country for interment in Canandaigua, N. Y.

WADE A. TAYLOR, a prominent steel manufacturer and chairman of the board of the American Zinc Products Co., Greencastle, Ind., died at Pasadena, Calif., Feb. 17, of heart disease. He was head of the Deforest Sheet & Tin Plate Co., Niles, Ohio, until that company was acquired by the Republic Iron & Steel Co. He is survived by his wife and daughter.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Rising Prices and Production Costs Accompany Greater Industrial Activity

Increased Output of Basic Commodities and Better Business Conditions in Wholesale and Retail Trade Mark Progress Since First of Year—Labor and Transportation Difficulties Foreseen

THERE is abundant evidence that the business revival has continued to gain momentum since the first of the year. Capacity operations on the part of most manufacturing industries and the volume of wholesale trade limited only by transportation difficulties are encouraging developments of the past 30 days. As yet there is but little of the speculative bidding and duplication of orders that usually accompanies an artificial business boom, but nevertheless some apprehension is being felt because of the surging rise in prices and production costs. Further advances in raw material prices threaten to carry manufactured goods to still higher levels and thereby enhance the danger of a runaway market, speculation and paper profits. Rather it is to be hoped that before long an equilibrium can be reached in industrial conditions so that production and consumption can proceed without the violent fluctuations noted during the past few months.

Many Industries Active

Cotton goods, pig iron, steel ingots, locomotives, zinc, bituminous coal, and wood chemicals are some of the industries showing the largest output since the boom of 1920. *The Survey of Current Business* on Feb. 26 makes the following comments on these industrial activities:

Cotton consumption by textile mills in January was the third largest in our history, totaling 610,375 bales. Wool receipts at Boston were very heavy in January, with foreign wool receipts the highest since April, 1921. Silk consumption increased to 31,680 bales, while stocks declined from the December high mark.

Pig-iron production at 3,229,604 tons was the largest since October, 1920, while steel-ingot production at 3,717,071 tons in January was not exceeded since March, 1920. Unfilled orders of the United States Steel Corporation increased after 2 months of declines and made a high record since February, 1921, at 6,910,776 tons. Merchant pig-iron shipments, unfilled orders and stocks increased, but sales declined.

Shipments of locomotives were the largest since January, 1921, and unfilled orders were the highest on record, at 1,788 locomotives.

Production of zinc rose to 92,634,000 lb., the highest since March, 1920, while stocks declined to 33,148,000 lb., the lowest since the armistice.

Production of bituminous coal in January amounted to 50,123,000 tons, the highest month with one exception since December, 1920.

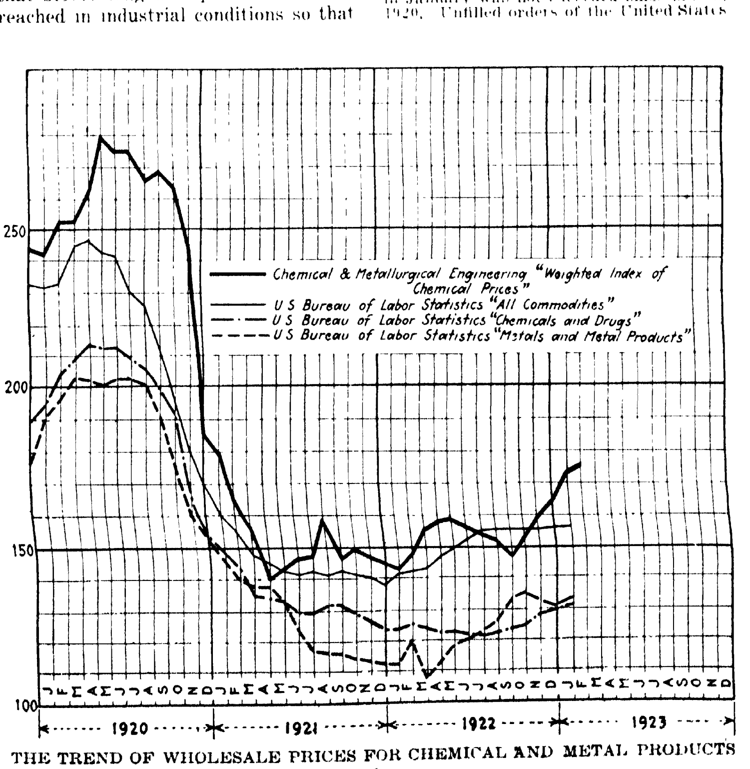
Figures on rubber tires, which have just become available, show a slightly increased consumption of rubber, but a falling off in production of tires. Shipments of tires increased and stocks were reduced.

Building contracts awarded in the 27 Northeastern States in January increased 1 per cent over December and 31 per cent over January, 1922.

Wood chemical plants produced about twice as much acetate of lime and wood alcohol in December as a year ago.

Receipts of turpentine and resin were higher than in January, 1922. Stocks of resin were larger than a year ago, but turpentine stocks were smaller.

Receipts and shipments of flaxseed were less than in December but greater than a year ago. Stocks declined to a total of only 82,000 bushels at Minneapolis and Duluth.



THE TREND OF WHOLESALE PRICES FOR CHEMICAL AND METAL PRODUCTS

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	176.71
Last week	176.38
March, 1922	156.00
March, 1921	157.00
March, 1920	252.00
April, 1918 (high)	286.00
April, 1921 (low)	140.00

The slight advance in this week's index number is due to fractional increases in the prices of caustic potash and linseed oil. Other prices were well maintained and no declines were reported.

Crude oil production continues at an altogether unprecedented rate. The American Petroleum Institute estimates that the daily average gross production for the week ended Feb. 24 was 1,784,700 bbl., as compared with 1,757,550 bbl. for the preceding week and 1,410,450 for the corresponding period in 1922.

Threatening Shortage of Labor

A factor which may act as an important check on further business expansion is the rather general shortage of labor. Many plants reported an inadequate labor supply in January, according to the United States Department of Labor. The monthly survey made by that department in 4,153 representative establishments in 43 manufacturing industries showed an increase of 1.4 per cent in the number of employees during January. The greatest increase was in the pottery industry

(36.9 per cent), due to resumption of production following a general strike. Fifty-two fertilizer plants reported an increase of 10.8 per cent. There were 3.3 per cent more workers in the 74 chemical plants that report to the department.

Chemical Prices Advance

For the past 3 or 4 months the average wholesale prices as recorded by the index numbers of the government and other agencies have been fairly constant. Closer study, however, reveals the fact that prices for certain basic commodities have stiffened considerably and this has been offset by declines in other prices. Since the first of the year the prices for the principal chemical and metal products have shown marked advances. These are indicated in the accompanying chart comparing this magazine's weighted index of chemical prices with the index numbers of the U. S. Bureau of Labor Statistics.

January Steel Production Breaks All Records

Steel production increased rather sharply in January, is increasing now, and promises to be higher still this month. January broke all records since the armistice, with the exception of March, 1920. March, 1923, is practically certain to beat that record and may possibly beat the highest record during the war. Both high points were reached on the eve of limiting influences developing. The high point in the war was in September, 1918, just before the influenza epidemic, with a rate of about 47,000,000 tons of ingots a year, while the high point since the armistice was in March, 1920, just before the "outlaw" railroad strikes began April 1, the rate being about 45,000,000 tons.

Ingot production ran at an average of about 34,500,000 tons a year for 6 months following the coal strike of April 1, 1922, then averaged 40,000,000 tons in the last 3 months of the year, and was at about 43,500,000 tons in January. Of late pig-iron production would have supported a slightly higher steel production rate than has obtained, the difference probably lying in mills replenishing pig-iron reserves, entirely depleted during the coal strike.

Business Failures Fall Off During February

Bradstreet's report on the total number of business failures during January, 1923, was 20 per cent less than the total for January a year ago, and the February total shows a decrease of 24 per cent from the like month of 1922. Measured in terms of liabilities, the January total fell 49 per cent from last year and that for February shows a decrease of 45 per cent.

These two months mark the recession from the high totals which have characterized these reports during the past 2 years.

Moderate Activity Again in Evidence in New York Chemical Market

Most Prices Well Maintained—Alkali Market Shows Improvement—Producers of Bicarbonate of Soda and Iodides Announce Advances

NEW YORK, March 5, 1923.

THE chemical market showed moderate activity during the past week, although trading was mostly for small quantities. Imported commodities continued to feature the market, due to the inability of German manufacturers to make any definite deliveries on old contracts. Permanganate of potash was very firm, and much higher prices were recorded among leading importers. Producers of bicarbonate of soda announced higher prices at the works, due to increased costs of production. The export inquiry for caustic soda showed a marked improvement and several large tonnage sales were reported to Japan and Europe. Soda ash has also shown a firmer tendency on spot. Arsenic continued along former levels, with buyers showing little disposition to purchase in round quantitties. Recent advances in copper sulphate were well maintained and the buyers showed additional interest in the general movement. Importers of glaubers salt reported a scarcity on spot and quoted \$1 per 100 lb. for shipment in bags. Manufacturers of iodides announced an increase of 15c. per lb. Importers of caustic potash were quite firm in their views and quoted much higher prices on limited stocks of spot material. Yellow prussiate of soda was somewhat weaker, due to the absence of any large buying interest.

Principal Price Changes

Alcohol—The tone of the market for methanol and denatured alcohol showed a marked improvement. Prices did not change, however, and denatured No. 1 continued at 38@40c. per gal. and methanol 97 per cent at \$1.25 per gal. in barrels.

Ammonium Sulphate—Spot goods remained in very scarce supply, due to the increased export demand. Producers reported a heavily sold up condition at the works. Resale material was quoted around \$3.85 per 100 lb., f.a.s., in double bags.

Arsenic—Spot goods ranged around 15½@15⅝c. per lb. Activity has slackened considerably and dealers were anxious to sell at fractionally lower figures.

Barium Carbonate—A better demand was reported for spot material and importers quoted \$72.50 per ton for spot goods. The general range was around \$72.50@\$75 per ton.

Bicarbonate of Soda—Leading producers advanced prices on all packages due to increased production costs. Barrels were quoted at 2c. per lb. f.o.b. works, with kegs at 2¼c. per lb.

Caustic Potash—Imported 88-92 per cent material on spot was in very scarce supply. Sales during the latter part of the week were recorded up to 8c. per lb. Shipments were quoted at 7⅝c. per lb. c.i.f. N. Y.

Caustic Soda—The export market showed material improvement, with several fair-sized sales reported to Japan and Italy at \$3.45@\$3.50 per 100 lb. The domestic market continued along firm lines, with quotations ranging around \$3.75 per 100 lb. ex-store. Contracts were quoted at \$2.50 per 100 lb., basis 60 per cent f.o.b. works.

Chlorate of Soda—A firm market was reported, with sales around 6½@6⅝c. per lb. f.o.b. works. Imported material held at the same level.

Copperas—Spot goods were quoted at 1⅜c. per lb. in barrels. Bulk material at the works held around \$16.50 per ton and \$19 in bags. The demand, however, was merely of a routine nature.

Fluoride of Soda—A quiet market was reported among importers, with quotations around 9c per lb. Domestic producers continued to quote 10c. per lb.

Iodides—Large producers announced advances on all iodides. Potassium iodide is quoted at \$3.75 per lb., with resublimed around \$4.55 per lb.

Permanganate of Potash—The market was in a very strong condition with importers quoting limited stocks on spot at 20c. per lb. Shipments were held at 18½c. per lb. duty paid. The new level represents an advance of 2c. per lb. during the past week.

Prussiate of Potash—Yellow prussiate was somewhat higher on spot, with quotations around 38@39c. per lb. The red variety remained at 80@85c. per lb. The demand showed considerable improvement.

Coal-Tar Products Active

Crude products continued very scarce on spot and producers reported a heavily sold up condition at the works. Buyers are experiencing extreme difficulties in locating appreciable quantities and the general tone of the market appeared quite strong. Naphthalene has shown material improvement and dealers have withdrawn former quotations on spot material. Phenol has also shown a marked improvement and quotations were advanced in most directions. Resale stocks have practically been taken off the market and available material now remains in first hands. Intermediates have continued in fair demand, with higher prices heard for alpha-naphthylamine, R salt and paratoluidine.

Cresylic Acid—Trading was rather quiet, due to the restricted offerings. A few odd lots on spot were quoted around \$1.50@\$1.65 per gal. Importers were said to be unable to market their material on account of the prevailing high duty.

Naphthalene—Prices were quoted at higher levels, due to the increased consuming demand. Sellers are quoting flakes at 6¾@7c. per lb. and balls at 7¾@8c. per lb.

Phenol—Cheap lots have been absorbed and higher prices were quoted by holders of spot goods. The U.S.P. prime crystals were quoted around 40@45c. per lb. The demand was quite active.

Satisfactory Business in the Chicago District

Actual Sales Not Large, but Prices Are Holding Firm—Imported Chemicals Scarce

CHICAGO, ILL., Mar. 1, 1923.

The chemical market in the Chicago district for the past 2 weeks was quiet with only a fair amount of business reported. Although no really large orders were consummated, all factors seemed satisfied with the volume they were doing. Prices held firm and as material was apparently in strong hands, there was little or no evidence of shading. Imported chemicals were all firm and in view of the conditions abroad a general advance would not be surprising.

Caustic soda was quiet and not much material moved on spot. The price was unchanged at $4.15 per 100 lb. for ground 76 per cent material and $3.50 for the solid. *Soda ash* was in routine demand and spot material was unchanged at $2.25 per 100 lb. *Caustic potash* was in good demand and the price was very firm at 8½@9c. per lb. for the imported 88-92 per cent. Importers of this material claim that the spot price is still below the replacement cost.

Alum in Better Demand

Potash alum was in better supply and the iron-free lump was available at 4½@5c. per lb. The powdered was still scarce and what was available was held at 8@8½c. per lb. *Sal ammoniac* was in good demand and the white granular of domestic manufacture was quoted at 8c. per lb. in small or moderate lots. *Ammonium carbonate* was quiet at 10@10½c. per lb. *Barium chloride* was offered in one direction at $95 per ton in ton lots. *Barium carbonate* was quiet and spot material could have been purchased at $80 per ton. Only one small lot of *white arsenic* could be located, and this was held at 17c. per lb. *Blue vitriol* was quite active, with a few outside lots still available at 6½c. per lb. *Carbon tetrachloride* was in plentiful supply and the general quotation was 9½@10c. per lb. *Carbon bisulphide* was unchanged in price and small or moderate lots were offered at 7@7½c. per lb. *Formaldehyde* was quiet, with a few outside lots quoted at 16c. per lb. *Glycerine* firmed up, but the spot price of 18½c. per lb. for c.p. material in drums was unchanged.

Due to fresh arrivals *phosphoric anhydride* was offered slightly lower at 35c. per lb. for 1-lb. tins in case lots. *Potassium bichromate* was in a firm position, with spot supplies held at 12½@13c. per lb. *Chlorate of potash* was scarce on spot, and only odd lots were available at 10@10½c. for the crystals and 9c. for the powdered. *Potassium cyanide* was unchanged at 55c. per lb. for single-case lots. *Permanganate of potash* was sharply advanced and 20@22c. per lb. was the range at which spot material was available. *Yellow prussiate of potash* was quoted at 40c. per lb. and was in fair supply. The *red prussiate* was still scarce, although slightly easier at 90c. per lb.

Linseed oil was in better demand during the past week, although the volume was far from large. Boiled oil was quoted at the close of today's market at $1.10 per gal. in single drums and similar quantities of raw at $1.08.

Turpentine continued to move slowly, but the price kept advancing. Today's market for single drums delivered to the buyers' store was $1.59 per gal.

Advances in Steel Prices Uniformly Accepted

Ingot Production Now at Record Rate of 45,000,000 Tons Per Year

PITTSBURGH, March 2, 1923.

Following advances in prices made by certain independent sheet manufacturers—other independents being out of the market—and reported a week ago, the American Sheet & Tin Plate Co. on Feb. 26 advanced its prices $3 a ton on blue annealed to 2.65c., $3 a ton on black to 3.50c., $5 a ton on galvanized to 4.60c. and $6 a ton on automobile sheets to 5c. These prices are somewhat below those of independents, which are 2.75@2.90c. on blue annealed, 3.60c. on black, 4.75c. on galvanized and 5.35c. on automobile sheets.

The leading interest was already practically sold up through June, while it had not opened order books for third quarter and will not do so for a month or two still. There was a double object in formally advancing prices at this time—to discourage customers from seeking to place additional tonnages, and to prepare the way for third quarter transactions.

At the same time the leading interest advanced its price on tin plate from $4.75 to $4.95 per base box, 100-lb. Late last week two large independent producers had formally announced advances in their prices to $5. Some independents had previously sold at $5 and even higher. Peculiar conditions exist in tin plate. Prices of steel and pig tin have advanced since order books were opened late last November for the current half year, when they were expected to decline, demand is proving remarkably heavy and shortage of labor and steel is likely to prevent full operation of the mills in the second quarter. Makers of packers' cans expect to be taken care of at a uniform price during a half year, on the ground that they sell their cans in advance, whereas tin plate mills are faced with a loss on any tin plate they may ship at $4.75, not covered by raw material bought at the former market. There is likely to be quite a range in selling prices in the next few months, according to the position and standing of the buyer.

Standard railroad spikes have been advanced, effective Feb. 27, from 2.90c. to 3.05c., for spikes $\frac{9}{16}$ in. and heavier.

No other important advances in steel products are recorded in the week, but all commodities show still more strength and there is more talk of premiums on small lots for early delivery, particularly in bars, shapes and plates.

Production at High Level

The rate of ingot production at the beginning of this month is probably well in excess of 45,000,000 tons a year. against a rate shown for January of about 48,500,000 tons. The average rate of production in 1920, a good year, and 1921, a poor year, in which there was consumption of steel and manufactures of steel previously made, was 30,000,000 tons a year—i.e., there was over 40,000 000 tons in 1920 and under 20,000,000 tons in 1921.

The very magnitude of the present demand for steel foreshadows a labor shortage in the spring, when outdoor work is to be resumed on a very large scale. The mills have a very fair labor supply now, but cannot meet competition of contractors, who simply bid whatever is necessary to get the men they must have to complete contracts. It is possible that there will be another general wage advance in the steel industry in the next month or two, even though another advance would be regarded as economically unsound.

Coke and Pig Iron

The buying movement in Connellsville furnace coke for second quarter, noted in last report as having just begun, has proceeded apace. According to the best estimate, more than 200,000 tons a month has now been placed under contract, all at $7 with the exception of one of the earliest contracts. This represents more than half the current supply, but production is going to increase, just as a number of furnaces, lately idle, are going to operate in second quarter. The market shows a strength which is remarkable and which was more or less unexpected. The coke market has taken its cue from the steel market rather than from the coal market, which has been declining and which promises prices during the remainder of the year at no more than a moderate margin above cost of production.

Pig iron is strengthening in practically all districts. In the local market bessemer has advanced 50c. in the week, and basic and foundry easily retain the advance of $1 recorded last week, at $27 and $28 respectively. Predictions are common that pig iron will soon reach $30, but such an advance is by no means assured, since consumers are already covered on very considerable tonnages for second quarter, and some idle furnaces are coming in.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 36 -	$0 38
Acetone, drums	lb	22 -	23
Acid, acetic, 28%, bbl	100 lb	3 15 -	3 40

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN—The Agricola Pipe Co., recently organized with a capital of $250,000 operating a plant at Anniston, Ala., for the manufacture of cast-iron pipe, has acquired the Campbell Co., with foundry on North 3rd St. The new owner will take possession of the property at once and purposes to make a number of improvements. It will be run for the production of cast-iron soil pipe. Otto Agricola is president, and Fred T. Agricola, secretary and treasurer.

ATMORE—The Cooper & Bannon Co., Oak Grove, Ala., has acquired a large tract of local property, heretofore held by the Pine Barren Mill Co., and plans for the establishment of a new plant for the production of turpentine.

California

SAN LUIS OBISPO—The United States Refractories Co. is planning for enlargements in its plant to cost about $60,000, including the construction of two new kilns. The company specializes in the manufacture of insulated brick, insulation powders, fire brick, etc. R. W. Hull, Sr., and J. H. Throop are heads.

GAVIOTA—Fire, Feb. 17, destroyed a large portion of the storage and distributing plant of the Associated Oil Co., with loss reported in excess of $750,000, including equipment. It is planned to rebuild. Headquarters of the company are in the Sharon Bldg., San Francisco.

MARYSVILLE—The Marysville Brick Co. has plans under way for additions to its plant to double approximately the present capacity, providing an annual output of close to 4,000,000 bricks. New electric-operated machinery will be installed. L. A. Williams is president.

LOS ANGELES—The Southwestern Shipbuilding Co., San Pedro, Los Angeles Harbor, has plans in progress for the construction of a new oil storage and distributing plant for company service, estimated to cost $300,000, with equipment.

OAKLAND—A porcelain and metal-enameling plant will be installed at the new local factory of the Koken Companies, Texas St., St. Louis, Mo., now in course of construction. The company manufactures barber chairs and kindred equipment. The new works are expected to be ready for service in about 60 days. Walter F. Koken is president.

Florida

HASTINGS—The Truman Fertilizer Co. has plans in progress for the erection of a new 1-story building at its plant.

Georgia

BUFORD—The Bona Allen Co., Inc., manufacturer of leather products, has work under way on extensions at its tanning plant for considerable increase in production, to include the installation of 200 new tanning vats and auxiliary equipment. Additions will also be made in the power department at the plant. Lockwood, Greene & Co., Atlanta, Ga., are engineers.

Illinois

CHICAGO—The Inland Steel Co., 38 South Dearborn St., has plans under consideration for enlargements in its works at Indiana Harbor, Ind., to include new open-hearth furnaces, finishing mills and other structures. It is purposed to increase the capacity about one-fourth, with heavier increase in the department devoted to the production of different grades of light steel. A preferred stock issue is being arranged to provide funds for the expansion.

CARLYLE—The Common Council has completed plans for the installation of a new filtration and purification plant at the municipal waterworks, and a call for bids on general contract has been issued. Dawson & Walraven, Springfield, Ill., are engineers.

CHICAGO—The Marquette Cement Co., 140 South Dearborn St., is taking bids on a general contract for the erection of a new 1-story building, 175x500 ft. at Elston and Redfield Aves., estimated to cost about $250,000. L. E. Ritter, Room 1707, 140 South Dearborn St., is engineer.

Indiana

JEFFERSONVILLE—The Interstate Public Service Co. will make extensions in its local artificial gas plant to increase the capacity about 300,000 cu.ft. per day. A new water-gas set and auxiliary equipment will be installed. It is purposed to have the work completed early in June.

Kansas

EUREKA—The Kansas City Refining Co., 1st Ave., Kansas City, Mo., is considering tentative plans for the construction of a new oil-refining plant in the vicinity of Eureka, estimated to cost close to $200,000. The project will be held in temporary abeyance until full field development for crude petroleum has been attained. E. W. Goebel is in charge.

Kentucky

CARTER—The Ashland Limestone Co. has perfected arrangements for the installation of a new crushing plant, with auxiliary operating departments, to develop a capacity of 3,000 tons per day. The plant will be located at Rock Crusher, near Carter. M. E. S. Posey is general manager.

Louisiana

BOGALUSA—The Great Southern Lumber Co., operating a local saw and lumber mill, will commence the construction of a branch works for the production of byproducts, including turpentine, pine oils and resin. Two processes of operation will be installed, covering the dry kiln and steaming method, and special treatment of resin timber picked from the green chain, respectively. It is purposed to have the branch plant ready for service in about 4 months.

Maryland

BALTIMORE—The Fourlock Tile Co., Candler Bldg., Market Place and Pratt St., has acquired a building formerly occupied by the General Minerals Co., vicinity of the Union Stock Yards, for a new plant for the manufacture of special interlocking concrete tile. Machinery and operating equipment will be installed at once to develop an initial capacity of about 1,000 tile daily; this output will be increased early in the spring. Tentative plans are under consideration for the establishment of branch plants at Hagerstown, Cumberland and Easton, Md. Frank H. Carter is secretary. The company was organized recently with a capital of $100,000.

Massachusetts

CHICOPEE—The Moore Drop Forge Co., Walter St., Springfield, Mass., has awarded a contract to Adams & Ruxton, Springfield, for the erection of a new 1-story building at its Chicopee Works, 75x100 ft., to be equipped as a heat-treating department. It is estimated to cost close to $70,000, including machinery. McClintock & Craig, 33 Lyman St., Springfield, are engineers.

BOSTON—The Crescent Tanning Co. has leased a floor in the building at 105 South St., for a new works. Immediate operations are planned.

Michigan

GRAND RAPIDS—The Grand Rapids Glass Co. has purchased property, 125x150 ft., at Fulton St. and Front Ave., for the erection of a new plant. Plans will be prepared at an early date.

JACKSON—The Grand Rapids Paint & Varnish Co. has plans under consideration for the erection of an addition to the local plant of the Central City Paint & Varnish Co., recently acquired. A project is also being discussed covering the construction of an entirely new works to replace the present factory, which is of old type. Alfred Hansen is resident manager.

MUSKEGON—The Brunswick-Balke-Collender Co., 629 South Wabash Ave., Chicago, Ill., has tentative plans under consideration for the rebuilding of the portion of its celluloid plant at Muskegon, recently destroyed by fire with loss estimated at $200,000, including machinery.

DETROIT—Roehm & Davison, 6440-52 Mack Ave., manufacturers of steel products, have awarded a general contract to Everett Winters, Book Bldg., for the erection of a 2-story plant addition at Mack and Beaufaite Aves., 150x152 ft., estimated to cost approximately $100,000, with equipment.

PLAINWELL—The Angle Steel Stool Co. has tentative plans under consideration for the erection of an addition to its plant.

Mississippi

MOSS POINT—The Southern Paper Co. has awarded a general contract to George J. Glover, Whitney Central Bldg., New Orleans, La., for the construction of its proposed plant additions, covering an area of about 75x800 ft., varying from 1 story to 5 stories high. The extensions will double approximately the present plant output and are estimated to cost close to $1,500,000 with machinery. A power plant will also be built. The work will be placed under way at once. George F. Hardy, 309 Broadway, New York, N. Y., is engineer.

Nevada

GOLDFIELD—The Bellehelen Merger Mines Co. has construction under way on a new mill at its local properties, to have a rating of 100 tons a day. It is estimated to cost approximately $125,000. The company is also arranging for extensive development work to include the installation of additional equipment. The Wellington Mines Co., Kansas City, Mo., is interested in the Bellehelen company.

New Jersey

STOCKTON—The Tillinghast Rubber Mfg. Co., manufacturer of rubber tubing and specialties, is planning for the rebuilding of the portion of its local mill destroyed by fire, Feb. 16, with loss approximating $100,000, including machinery. The equipment installation was valued in excess of $30,000. Walker Smith is president, and William J. McLaughlin, secretary.

BELLEVILLE—Daniel H. Higgins, Edgewater, N. J., manufacturer of dyes and kindred chemical products, has taken title to the former plant of the Thomson Machine Co., Main St., Belleville, consisting of three factory buildings on a half-acre tract of land, with aggregate of 20,000 sq.ft. of floor space. Plans are under way for the establishment of a new dye and chemical works at this location.

BLOOMSBURY—The Bloomsbury Graphite Co. has preliminary plans under consideration for the rebuilding of the portion of its plant destroyed by fire, Feb. 20, with loss estimated at $40,000, including equipment. The company manufactures graphite products, foundry facing, etc.

NEWARK—The Hamilton Tanning Co. has leased property at Wright St. and Ave. A for a term of years, comprising a 1-story building 125 ft. long, for the establishment of a new leather tannery. Immediate possession will be taken.

CAMDEN—Fire, Feb. 20, destroyed a portion of the chemical plant of the Mechling Brothers Mfg. Co., Line St. and Cooper River, South Camden. It originated in the sulphur department. An official estimate of the loss has not been announced. Plans are under consideration for immediate rebuilding.

New Mexico

SANTA FE—The Navajo Gasoline Production Co. is planning for the construction of gasoline extraction plants in the San Juan basin district.

New York

NEW YORK—The Consolidated Products Co., Inc., 15 Park Row, New York, has inquiries out for equipment for installation in a chemical plant, including disintegrators, filter presses, driers, evaporators, grinding machinery and kindred machinery.

ROME—The Rome Brass & Copper Co. has taken bids on a general contract for the erection of a new building at its Chicago, Ill., works, to be 1-story and basement,

50x180 ft., estimated to cost approximately $50,000. M. K. Williams is in charge.

Ohio

SEBRING—The French China Co. is planning for the early erection of an addition to its plant, including the installation of two new pottery kilns.

CAMBRIDGE—The Cambridge Steel Products Co., recently organized with a capital of $100,000, will take over and operate the local plant of the Cambridge Steel Co. Possession will be taken at once. Extensions and improvements are contemplated.

SEBRING—The Saxon China Co. has preliminary plans under consideration for enlargements in its plant, to include the construction of three new kilns. It is purposed to increase the output about one-third.

CAMBRIDGE—Interests which recently acquired the plant of the Guernseyware China Co. are perfecting arrangements for the early resumption of operations for the manufacture of a line of hotel chinaware. Improvements will be made in the plant and equipment for this service.

Oklahoma

TULSA—The Union Carbide Co., 30 East 42nd St., New York, N. Y., manufacturer of carbide, acetylene, commercial oxygen and kindred products, is said to be planning for the erection of a new plant in the vicinity of Tulsa, estimated to cost close to $350,000, with machinery.

Pennsylvania

READING—The Pennsylvania Electric Steel Co. has acquired the local plant of the Driscoll-Rees Steel Co. and plans to equip and utilize the property for the production of high-grade tool steel, to be produced by means of a new process. It is purposed to have the plant in full operation at an early date.

CHAMBERSBURG—The Chambersburg Gas Co. will make improvements and extensions in its artificial gas plant, with additional equipment installation estimated to cost about $60,000. Contracts are being let.

PITTSBURGH—The Pennsylvania Paper Stock Co., 516-26 1st Ave., has tentative plans under consideration for the rebuilding of the portion of its plant, destroyed by fire, Feb. 18, with loss estimated at close to $75,000.

PHILADELPHIA—Fire, Feb. 17, destroyed a portion of the acid works of the Wilson-Martin Co., Snyder Ave. and Swanson St., with loss estimated at $12,000. It will be rebuilt.

PHILADELPHIA—The Precision Grinding Wheel Co., 8301 Torresdale Ave., has filed plans for the erection of a new 1-story building at its plant.

CONSHOHOCKEN—A 1-story foundry, 125x195 ft., will be erected by the Montgomery Foundry & Fittings Co., located at Washington and Cherry Sts., for the production of iron and other metal castings. Work will be commenced early in April.

LEBANON—The Lebanon Iron Co. is planning for the immediate rebuilding of its puddle mill and adjoining buildings, destroyed by fire, Feb. 18, with loss estimated at close to $150,000, including ten furnaces and auxiliary equipment. John D. Brown is general manager at the plant.

BATH—The Pocono Foundry Co. has tentative plans under consideration for extensions and improvements in its plant.

Tennessee

CHATTANOOGA—The Southern Sheet Steel Co., recently organized with a capital of $1,100,000, is perfecting plans for the erection of its proposed new mills at Glendale, Tenn., where a site has been secured on the Tennessee River. The initial works will comprise two open-hearth furnaces, each with rated capacity of 60,000 tons per annum; a number of rolling mills, with total annual output of 55,000 tons and other miscellaneous mill and sheet mill buildings, with power house. The plant is estimated to cost close to $80,000. W. J. Lynch is vice-president and general manager.

Texas

AUSTIN—A chemical laboratory will be installed in the new biology building to be constructed on the campus, University of Texas. The structure will be 3-story, 66x191 ft., and will cost in excess of $250,000. Herbert M. Greene, Dallas, Tex., is architect.

Virginia

SUFFOLK—The American Brick Corp. will commence immediately the erection of a new plant on local site, to be equipped for an initial capacity of 25,000 to 30,000 bricks per day. It is estimated to cost approximately $35,000. R. L. Jacobs is president; and Lewis G. Brothers, secretary.

NORFOLK—Adolph Segal, Philadelphia, Pa., sugar operator, is perfecting plans for the construction and operation of a new sugar refinery on site secured at Norfolk. It will consist of a number of buildings with power house, and is estimated to cost in excess of $3,000,000, with machinery. It is expected to develop an output of close to 3,000 bbl. of refined sugar daily. Charles B. Hughes, president of the Hughes-Ellis-Howell Corp., 403 Boush St., Norfolk, is interested in the project.

NORTON—L. A. Ballenby, Norton, is organizing a company to construct and operate a local plant for the manufacture of brick and tile products. Work will soon be commenced.

Washington

NEWPORT—The Pacific Fir Co. has plans under way for the construction of a new creosoting and wood-treatment plant on local site, estimated to cost approximately $25,000.

SEATTLE—The Builders Brick Co., 3700 9th St., South, will make improvements in its plant, including the construction of a new kiln.

VANCOUVER—The Columbia River Paper Mills Co. is perfecting plans for the construction of the initial unit of its proposed new mill, estimated to cost in excess of $200,000, with machinery. F. W. Leadbeater is president.

Wisconsin

NEENAH—The Valley Paper Mills, Inc., Wisconsin Ave., will take bids about March 15 for the erection of the superstructure of its proposed new mill in the Blair Springs district, foundations for which have been laid. The plant will be 2- and 3-story, 80x670 ft., and is estimated to cost $750,000, including machinery. Cahill & Douglas, 217 West Water St., Milwaukee, are mechanical engineers for the work. G. W. Burnside is head.

Industrial Developments

RUBBER—The Kelly-Springfield Tire Co. is operating at full capacity at its plants at Akron, O., and Cumberland, Md., and will maintain this schedule for an indefinite period. The last noted mill is now giving employment to about 2,500 persons, and plans are under way for early expansion. Effective Feb. 21, the wages at the mill were advanced 10 per cent, affecting all hourly rates and piece-work production.

The Atlas Automobile Tire Co., Bethlehem, Pa., is running at maximum capacity, and in order to handle heavy incoming business plans are being arranged for extensions in the mill facilities.

The Mason Tire & Rubber Co., Akron, O., is operating at full capacity, on a basis of about 6,000 tires per day. Full production is also being maintained at the branch mill at Bedford, O., formerly occupied by the Owen Tire & Rubber Co.

CERAMIC—The Verdigris Valley Vitrified Brick Co., Independence, Kan., recently acquired by new interests, is planning for the early resumption of production at the plant, now closed down for machinery repairs. W. E. Bullis, Topeka, Kan.; and M. B. Gilkerson, Wichita, Kan., head the new organization.

General ware plants in the vicinity of East Liverpool, O., are running full, with incoming orders in excess of immediate production.

The Independent Brick Co., Trenton, N. J., is maintaining operations at regular capacity at three of its four plants. It is expected to continue on this basis for an indefinite period. Charles T. Dunham has been re-elected secretary, treasurer and general manager of the company.

The Crouse Clay Products Co., Akron, O., is maintaining full production at its plant and purposes to continue on this status for some time to come. The company has recently installed new machinery and equipment to provide for an advance of about 30 per cent in capacity.

The D. E. McNicol Pottery Co., Clarksburg, W. Va., manufacturer of Rockingham and yellow ware, is operating at full capacity with regular working force. Orders on hand insure this schedule for some time to come.

The Glenrock Brick Co., Glenrock, Wyo., is planning for the resumption of full-time production at its plant as soon as weather conditions permit, within the next 3 or 4 weeks. Continuous operations will be then scheduled for an indefinite period.

LEATHER—The Standard Kid Co., Wilmington, Del., is maintaining close to normal production at its local tannery, and is now running on a basis of about 850 dozen skins per day.

The William Amer Co., Philadelphia, Pa., is concentrating production on novelty leather at its local glazed kid tannery, with employment of regular working force. With the advent of spring, it is expected to revert to the manufacture of staples, with increased operations.

The American Hide & Leather Co., New York, N. Y., is advancing production at its different New England and Middle West tanneries, with increased working forces. For greater production in the New England district, the company has acquired the modern tannery at Peabody, Mass., formerly owned and operated by H. S. & M. W. Snyder, Inc., and will take possession early in April. It aggregates approximately 250,000 sq.ft. of floor area, and has facilities for an output of 1,500 dozen skins per day. The new owner expects to inaugurate production at the plant at an early date, with normal working quota.

PAPER—The International Paper Co., 30 Broad St., New York, N. Y., has established a capacity schedule at all of its newsprint mills for the first time in 2 years, and will continue on this basis for an indefinite period. Large working forces are being employed.

The Kennedy Car Liner & Bag Co., Shelbyville, Ind., is adopting a night shift at its paper products plant at Greensburg, Ind., using a portion of the working force heretofore employed at the Shelbyville mill, recently destroyed by fire and now being rebuilt. The extra working schedule will be continued for some time to come.

The Backus & Brooks Co., Kenora, Man., is planning to commence operations at its new local pulp mill, recently completed at a cost said to be close to $2,000,000. The plant has a rated capacity of 50 tons of material per day and it is purposed to develop operations at maximum, with full working force.

OIL—The Foco Oil Co., Franklin, Pa., recently organized to take over and operate the local refinery of the Lakeside Refining Co., is arranging for immediate production at the plant, with full working force.

Oil refineries in Western Pennsylvania are advancing production and adding to their working quotas.

The Sinclair Consolidated Oil Corp., 45 Nassau St., New York, N. Y., is operating at its Oklahoma, Kansas and other midwest plants on a production basis of about 35,000 bbl. per day. The Sinclair Crude Oil Producing Co., a subsidiary organization, has stock on hand at the present time totaling 30,000,000 bbl. of crude oil to be run through the refineries.

IRON AND STEEL—The Carbon Iron & Steel Co., Parryville, Pa., has resumed operations at its furnaces, which have been idle for more than 24 months past. Employment will be given to about 100 men.

Witherbee, Sherman & Co., New York, N. Y., have blown in the small blast furnace at their plant at Port Henry, N. Y., following relining and repairs, and purpose to keep the unit in service for an indefinite period. A larger furnace at the plant, now in course of construction, will be lighted as soon as completed.

Iron and steel plants in the Youngstown, O., district have advanced production to a point of about 90 per cent of capacity, the highest record for a number of months past.

The Gulf States Steel Co., Birmingham, Ala., is now operating five of its six blast furnaces, and will continue at maximum for an indefinite period.

The Sharon Steel Hoop Co., Sharon, Pa., is running at 100 per cent capacity at its local mills for the first time in 3 years.

The Bethlehem Steel Co. has resumed operations at the puddle mill at its Central Works, Lebanon, Pa., after an idle period of a number of months. The plant will be run on a double turn, and is said to have sufficient orders on hand to insure continuance on this basis for 6 to 8 months to come.

A total of 110 blast furnaces devoted to the production of pig iron are now in operation in the Pittsburgh, Pa., district. Practically all of the stacks that are idle are those devoted to merchant iron.

MISCELLANEOUS—The Carnegie Steel Co., is making ready to resume operations at its coke plant at the Farrell, Pa., works, which has been idle since March, 1921. Production will also be inaugurated at the benzol

and other byproduct plant units. Employment will be given to about 600 men.

The Ruggles & Raedemaker Co., Mainstee, Mich., operating salt properties, has taken over the plant and business of the Petit Salt Co., Milwaukee, Wis. The combined production makes the purchasing company one of the largest salt producers in the country. Full operations with regular working forces are planned.

The Ross-Meehan Foundry Co., Chattanooga, Tenn., specializing in the production of steel castings, is running at maximum capacity with full working force and will continue this schedule for an indefinite period.

Heavy production is in progress at the different lead and zinc properties in the Northeastern Oklahoma section. Practically every plant that can be operated profitably is on the full-time producing list.

New Companies

The Bond Chemist Shop, Inc., 338 Asylum St., Hartford, Conn., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical compounds. George L. Rappoport is president, A. G. Bush treasurer, and George L. Day, vice-president and secretary.

The Tucker Chemical Mfg. Co., Paducah, Ky., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are T. A. Miller, C. E. Pace and W. C. Richman, all of Paducah.

The Goldman Paper & Paper Stock Co., Philadelphia, Pa., has been incorporated with a capital of $250,000, to manufacture paper products. Harry Goldman, 320, Turner St., is treasurer.

The Camden Glass Works, Inc., Camden, N. J., has been incorporated with a capital of $10,000, to manufacture glass products. The incorporators are Harry Rosenthal, 105 Arch St., Camden, M. A. Mason and M. A. Maguire. The first noted represents the company.

The Al-Sano Chemical Products Co., 29 South La Salle St., Chicago, Ill., has been incorporated with a capital of $300,000 to manufacture chemicals and chemical byproducts. The incorporators are E. S. Fisher, Fern Warren and L. E. Sweitzer.

The King Tire & Rubber Co., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated with a capital of $1,[illegible],000, to manufacture tires and other rubber products.

The Star Producing Co., Albany, N. Y., has been incorporated with a capital of $200,000, to manufacture petroleum products. The incorporators are W. H. Link and T. L. Hunt, Albany. The company is represented by W. M. Miller, attorney, Schenectady, N. Y.

The Chester Brick Co., Chester, Pa., has been incorporated with a capital of $50,000 to manufacture brick, tile and other burned clay products. Edward C. Burton, Chester, is treasurer.

The United States Chemical Corp., Boston, Mass., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. Thomas L. Thistle is president and Oliver E. Brush, 1066 Commonwealth Ave., Boston, treasurer.

The Leeds Concrete Products Co., Leeds, Ala., has been chartered under state laws to establish and operate a local plant for the manufacture of concrete brick, pipe and kindred products. H. M. Judge, Leeds, is president.

The Columbia Products Corp., Newark, N. J., has been incorporated with a capital of $50,000 to manufacture asbestos products. The incorporators are R. J. and Joseph Faatz, and Arthur W. Palmer, 5 Merchant Place, Newark. The last noted represents the company.

The Monroe Board & Lining Co., Monroe, Mich., has been incorporated with a capital of $150,000, to manufacture paper products. The incorporators are William G. Gutmann, Fred J. Motz and J. Douglas Miller, 427 West Elm Ave., Monroe. The last noted represents the company.

The Hi-Power Co. of New Jersey, Inc., Hoboken, has been incorporated with a capital of $30,000, to manufacture battery fluids, chemical products, etc. The incorporators are J. D. and H. E. Pierson, and Rudolph Schroeder, 81 Washington St., Hoboken. The last noted represents the company.

The Calumet Castings Corp., 11417 South Michigan Ave., Chicago, Ill., has been incorporated with a nominal capital of $5,000 to manufacture iron and other metal castings. The incorporators are Julius C. Greenbaum, William S. Newburger and R. Wagman.

The Lubbock Cotton Oil Co., Lubbock, Tex., has been incorporated with a capital of $150,000, to manufacture cotton oil products. The incorporators are J. W. Simmons, Jr., F. J. Phillips and H. M. Simmons, all of Lubbock.

The MacLeod Foundry Co., Detroit, Mich., has been chartered under state laws to manufacture iron and other metal castings. The incorporators are Casper Brown and Malcolm MacLeod, 1128 Marlborough Ave., Detroit.

Talens & Son, Inc., Newark, N. J., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, etc. The incorporators are Hilbrand Talens, W. Howard Demarest and William M. Bosman, 985 Springfield Ave., Newark. The last noted represents the company.

The Bement Oil Co., Terre Haute, Ind., has been incorporated with a capital of $250,000, to manufacture petroleum products. The incorporators are A. B. Bement, H. E. Rogers and C. A. Morrison, all of Terre Haute.

The Oxygol Corp., New York, N. Y., care of Briesen & Schrenk, 50 Church St., New York, representatives, has been incorporated with a capital of $100,000, to manufacture chemical products. The incorporators are S. J. Bohannon, B. Brehm and T. McErlean.

The R. & K. Glass Co., Wellsburg, W. Va., has been incorporated with a capital of $25,000, to manufacture glass products. The incorporators are W. D. Shields and A. J. Rowing, both of Wellsburg, and H. E. Kightlinger, Beech Bottom, W. Va.

The American Chemical Products Co., 31 New St., Newark, N. J., has filed notice of organization to manufacture and deal in chemical and oil products. The company is headed by J. William O'Connor.

The Birmingham Glass Mfg. Co., 29 South La Salle St., Chicago, Ill., has been incorporated with a capital of $250,000, to manufacture glass products. The incorporators are Harry C. Bryson, Richard T. Robb and E. R. Owen.

The Bacon Hill Brick Co., Elkton, Md., has been incorporated with a capital of $50,000, to manufacture brick, tile and other burned clay products. The incorporators are John Mattiussi and James F. Evans, both of Elkton.

The Monterey Bay Portland Cement Co., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $3,000,000, to manufacture portland cement.

The Hopewell Color & Chemical Co., Hopewell, N. J., has been incorporated with a capital of $50,000, to manufacture chemicals, colors and affiliated products. The incorporators are Peter M. Horn, Edward and W. Herbert Jones, all of Hopewell. Edward Jones, Hopewell, is the registered agent for the company.

The Indiana Sun Rise Oil Co., Patricksburg, Ind., has been incorporated with a capital of $50,000, to manufacture petroleum products. The incorporators are J. M. Henderson, N. B. Love and James Andrew, all of Patricksburg.

The Stradford Mfg. Co., Philadelphia, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., representative, has been incorporated under Delaware laws with capital of $1,250,000, to manufacture chemicals and chemical byproducts.

Capital Increases, etc.

The Northern Indiana Brass Co., Elkhart, Ind., has filed notice of increase in capital from $10,000 to $100,000 for proposed expansion.

The Atlas Leather Mfg. Co., East St. Louis, Ill., has filed notice of change of name to the Atlas Board & Paper Co., and in the future will specialize in the manufacture of paper products.

The Glenn-Osage Oil Co., Grand Rapids, Mich., has arranged for an increase in capital from $100,000 to $200,000.

The Hudson Oil Co. of Delaware, 135 Broadway, New York, N. Y., has filed notice of increase in capital from $3,000,000 to $5,000,000.

The Broughton Brick & Tile Co., Broughton, Ill., has filed notice of dissolution under state laws.

The Brooklyn Color Works, Inc., Stewart Ave., Brooklyn, N. Y., has arranged for an increase in capital from $30,000 to $100,000.

The Ross-Meehan Foundries, Inc., Chattanooga, Tenn., has filed notice of increase in capital from $60,000 to $1,260,000 for general expansion. G. F. Meehan is president.

The Standard Paint Co., Texarkana, Ark., has arranged for an increase in capital to $50,000 for proposed expansion. C. K. Faison is president.

The Harrisburg Shale Brick Co., Harrisburg, Pa., has called a special meeting of stockholders on April 14 to arrange for an increase in capital from $60,000 to $120,000 for general expansion. Jacob H. Foreman is secretary and treasurer.

The Goodyear Tire & Rubber Co., Akron, O., is disposing of a preferred stock issue of $14,505,800, a portion of the proceeds to be used for general financing, expansion, etc.

The Chino Copper Co., 25 Broad St., New York, N. Y., is considering a new stock issue to total $150,000, the proceeds to be used for plant extensions and improvements.

Coming Meetings and Events

American Association of Engineers will hold its annual convention in Norfolk, Va. May 7 to 9.

American Chemical Society will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

American Electrochemical Society will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

American Foundrymen's Association will hold a meeting in Cleveland, O., April 28 to May 4.

American Gas Association will hold its annual convention the week of Oct. 15 at Atlantic City. An elaborate exhibition of gas-making and gas-utilization equipment is planned.

American Institute of Chemical Engineers will hold its summer meeting June 20-23 at Wilmington, Del.

American Leather Chemists Association will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

American Oil Chemists' Society will hold its annual meeting at the Eastman Hotel, Hot Springs, Ark., April 30 and May 1.

American Society for Testing Materials will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

International Chamber of Commerce will hold its second general meeting in Rome, Italy, March 19-26, 1923.

Iron and Steel Institute (London) will hold its annual meeting May 10 and 11 at the House of the Institution of Civil Engineers, London, S. W. 1.

National Foreign Trade Council has postponed its annual conference from April 25, 26 and 27, to May 2, 3 and 4. It will be held in New Orleans, La.

New Jersey Chemical Society holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

Society for Steel Treating—Eastern sectional meeting will be held June 14 and 15 in Bethlehem, Pa.

Society of Industrial Engineers, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A Paper Industries Exposition will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 New York, March 14, 1923 Number 11

The Absurdity Of Dollar Gasoline

POLITICIANS, like the poor, will probably be with us always and their railings will continue sorely to try the patience of a tolerant people. With the adjournment of the Sixty-seventh Congress a sigh of relief went up from the entire country because for nine months at least we are to be immune from the radical eruptions that have characterized recent sessions of our legislators.

Most of the politicians' vituperations have been of a sort we could pass over and forget, for they could be traced to the more or less familiar prejudices and party feuds. On the very last day of the session, however, there was one flagrant piece of abuse that cannot escape without protest. We refer to the infamous report, presumably prepared by Senators LA FOLLETTE and BROOKHART, on the petroleum industry and more particularly to its evident purpose to mislead the public into believing that gasoline will shortly go to a dollar a gallon unless an export embargo is placed on it. Although absolutely no supporting evidence was brought out in the extended hearings before the Senate sub-committee, the politicians nevertheless authorized this conclusion to confirm their earlier charges and to show the world at large that they were taking the part of the poor automobile owner against the great and ruthless oil monopolies.

To the technical man the possibility of dollar gasoline, at least within the present generation, is a positive absurdity. The public's best assurance that the price of motor fuel will not soar to prohibitive levels is in the uninterrupted advance of petroleum technology as reflected in the greater utilization of crudes, in improvements and economies in refining methods and finally in the broadened utility of low-grade products through the development of cracking processes on the one hand and advances in engine design on the other.

Furthermore the production of gasoline substitutes will effectively check any such advance in prices. Industrial alcohol can be produced at a cost not greatly in excess of 25 cents a gallon. While there might be some question as to the immediate supply of raw materials for such a fermentation program, it is scarcely conceivable that there could ever be any permanent shortage of the wide variety of carbohydrate and cellulose materials that can be used for alcohol production. And, of course, our oil-shale resources represent an untapped source of petroleum substitutes that will be developed long before gasoline ever mounts to a dollar a gallon. Our friend Dr. MCKEE estimates that the shale-oil industry can prosper with gasoline at 35 cents a gallon. Nor should low-temperature distillation of coal be overlooked, for here is a demonstrated source of many valuable liquid fuels. Many other lines of fuel research and discovery might be listed, among them the experimental production in France of a synthetic gasoline from crude vegetable oils and the fact that the Germans have hydrogenated coal and coal-tar products to obtain a wide variety of fuels and lubricants. Some of these are still in the hazy status of day dreams, but dollar gasoline would undoubtedly turn many of them into lucrative commercial enterprises.

The whole fabric of the report is political buncombe, however, and as such is unworthy of serious consideration. Our principal complaint is that a legitimate industry has been forced to submit to months of senseless and costly investigation only to find that its case had been prejudged and that the "conclusions" of the committee are but a restatement of individual opinions already aired by the political demagogues.

The Purpose Of a Standard

ELSEWHERE in this issue is a brief statement by W. W. SKINNER, one of the most experienced of the government experts on the establishment of food standards. He discusses this subject with unusual effectiveness, pointing out in his comment with great force the basic reasoning in the establishment of commercial specifications and requirements of food quality.

The arguments advanced by Dr. SKINNER might equally well be applied to the commercial practices of many other industries. Of course the other industries are not subjected to governmental regulation; but the principle of fair relationship between buyer and seller applies equally. It would seem appropriate, therefore, to apply generally the three fundamental considerations which govern the federal officials in their deliberations regarding food standards. These fundamental functions of a standard, paraphrased for general application, are:

1. To define products so as to prevent unfair competition, since one effect of intelligently used standards of trade is the promotion of better business methods and better business ethics.

2. To define products so that inspection laboratories may have a uniform and generally accepted guide in applying the standards to purchases of the products.

3. To define products so that the consumer may discern quality and exercise a discriminating choice, and that the producer may know and meet such a discriminating demand. In other words, to create a condition in the commerce of chemical products where vendor and vendee speak a common language.

We commend these principles to the study of all—particularly to the manufacturers of heavy chemicals.

On the Comforts Of Patience

THE news is going around of a French invention to make artificial wool out of cotton by impregnating the fiber with a protein substance such as glue, gelatin, egg albumen or casein, which has first been broken down by an acid and then rendered insoluble in a water bath. Good wearing qualities and other merits are claimed for the new fabric.

We have no patience with troublesome skeptics that are constantly discouraging faith in invention and research. We have always felt that once the problem of the cellulose molecule is solved, we may look for all sorts of new fabrics and new materials. This invention comes a little early, but we wish to record our faith in the advent of artificial wool eventually, and to admit that some day desirable fabrics may be developed by a proteinizing process with cellulose. But development is always slow and painful. Sometimes it pays to wait! In the meantime we are not planning to array ourselves during the hot weather next summer in a suit of cotton clothes impregnated with glue. We should grow a little nervous over the possibility of sticky sequelæ of photochemical reactions as we pursue our way along the hot humid streets toward Tenth Avenue and 36th Street.

An Achievement in Current Statistics

WE HAVE often referred to the value of statistics, particularly when they are issued in time to be of current interest to industry. In this connection a recent achievement of the Chemical Division of the Department of Commerce is worthy of special comment. Statistics for the coal-tar dyes imported through the port of New York during the month of February, 1923, were carefully compiled from the customs invoices, analyzed by the dye experts of the Commerce Department and the United States Tariff Commission, and made available in mimeographed form on March 6. Certainly this is an example of dispatch which other governmental agencies might well emulate And the statistics themselves were not mere totals of poundage and value. In addition to such figures each dye was classified on the basis of its chemical composition and listed according to its Schultz number; the usual trade names were given, also the name and address of the foreign manufacturer, and, finally, the percentage of quantity by the countries of origin. A small proportion of the entries, which could not be identified on the basis of the Schultz Farbstoff Tabellen, were grouped according to their method of application - that is, as acid, basic, vat, mordant, chrome or sulphur colors.

But it may be asked, Is all the detailed work entailed in this compilation and the department's special effort to issue it so promptly really worth while? The answer, we believe, is to be found in the significant information brought out in the February report. During that month \$52,000 worth of imported dyes, or 26.2 per cent of the total, came from Italy, or was sold on the American market by Italian concerns. That fact is worth looking into, for Italy has never been regarded as a serious competitor of the I.G. The department's detailed data on the dye manufacturers, however, show that practically every pound of the Italian shipments, and a large proportion of those imported from France, were actually made in Germany. They were products granted the Italian Government as reparations and resold to American importers in order to realize their gold value. The treaty of Versailles especially provides against the resale of reparation products, but since we are not a party to that treaty we can have no grounds for an official complaint. Furthermore, the practice has already become quite general in the case of pharmaceuticals and apparently with the consent of all interested parties.

The second significant deduction from these statistics is proof of the unhappy effect that the French occupation of the Ruhr is having on the dye industry of Switzerland. Apparently the Swiss manufacturers are suffering severely from interruption of their supply of crudes, intermediates and other raw materials which usually originated in the occupied region of Germany. The amount of Swiss dyes received by the United States in February was only 10.4 per cent of the total. In the year 1921, 40.5 per cent of our dye imports was of Swiss origin.

These are facts that are of immediate importance to the domestic manufacturer of dyes and coal-tar products. At the same time they are indisputable evidence of the value of current statistics. The Department of Commerce and the Tariff Commission are to be congratulated on their excellent work, and it is to be hoped that eventually the reports may be extended to cover all of the important products of American industry.

Congress Adjourns

THE dust and smoke from the battle of the "blocs" has now settled sufficiently to permit at least partial appraisal of the outcome of the contests that were waged so violently in the last Congress. Perhaps the most conspicuous conclusion that a fair-minded appraiser reaches is the fact that this Congress was divided into groups having common interest, and not ruled by the customary party system.

Those who have opposed FORD'S Muscle Shoals proposal and the other variations in contract for lease or for sale of the power and the nitrate properties in that locality finally can rest in comfort for some months. The Congress which just closed left the situation substantially where it found it, for the Wilson Dam construction is continuing, the nitrate plants still belong to the government, and the disposal of the power from this huge development is still to be determined. In failing to secure any action upon Muscle Shoals the agricultural bloc failed in one of its most cherished objects. This same group also failed to enact the legislation providing ten million dollars for the purchase of calcium arsenate and nitrates for resale to the farmers at cost. These are two striking evidences that the interest of a single group in the community, powerful though it may be, does not dominate the Congressional situation wholly. It may obstruct, but it can seldom enact.

At the end of the session there remained without action the legislation on reclassification of the government service. Also no final action was taken on the proposed National Hydraulic Laboratory, though a favorable report to the Senate was secured. The bill proposing conservation and development of helium resources also failed through faulty management. After full and apparently very satisfactory hearings before the Public Lands Committee of the House, this bill was never given further attention because the commit-

tee finally decided that it was without jurisdiction in the matter and that the Committee on Military Affairs would have to begin all over again in the next Congress. Another bill that failed to get action in closing days was the bill for the regulation of radio communication.

Taken all together the Sixty-seventh Congress undoubtedly faced problems of exceptional magnitude and exceptional difficulty. It accomplished some things. In many more particulars it failed of accomplishment.

One feature, however, of the work of this Congress holds definite promise for chemical industry. Forced largely thereto by the Fordney-McCumber tariff act and the Muscle Shoals impasse, this Congress has given vastly more hours to the debate of chemical and chemical engineering matters than any of its predecessors. While the immediate outcome of this debate may not be wholly to the liking of those affected, still they can console themselves that they suffer in a good cause. Chemical industry needed a press agent and the Sixty-seventh Congress, following after the recent war, has proved the best it ever had.

Why Did It Break?

TWO years ago we commented editorially on the great number of unsolved and obscure problems concerning the endurance of metal to repeated loads. They appeared to be so numerous that solution by series of direct experiments—and what experiment requires more time than 100 million cycles?—seemed impossible. At that time a logical explanation of the mechanism of fatigue was in hand, but unfortunately we had no "conversion factors," so to speak, whereby we could predict the behavior of a given metal from easily determined physical properties.

In the meantime it has been proved to everybody's satisfaction that elastic metal can endure so-called "fatigue stresses" indefinitely, provided they fall within the safe range. In other words, there is no reason to fear eventual rupture of the most carefully designed and fabricated turbine shaft, even though it run on and on for years. BAUSCHINGER—one of the earliest investigators—proposed the theorem that the elastic range and fatigue range are identical. If elastic limits are taken from a tension test bar, this statement does not correspond to experience—hardened steel or annealed copper does not deform in an elastic manner—that is, the stress-strain curve really *curves* from the origin—yet both of these metals have been shown to have endurance properties as well defined as wrought iron.

Professor JENKIN, of Oxford, has recently constructed a little model which explains this apparent anomaly, and in fact will probably furnish engineers the "conversion factors" long wished for. Like all inspirations of genius, it is beautifully simple, and represents the action of crystals as they slip when overloaded. It can be set so that any crystal can have any desired internal strain, short of its own elastic limit in either compression or tension. Then its action on the aggregate—the metal piece—can be observed.

This model confirms BAUSCHINGER'S theorem entirely. It is only to be noted that the elastic limit referred to is the elastic limit of the weakest crystal in the metal. That fact we could have assumed from the microscopic work of EWING, ROSENHAIN and HUMFREY, who discovered the facts now contained in all our textbooks: that a fatigue failure starts in a crystalline slip, which gradually opens up into a crack and extends itself by splitting. Clearly slip will occur when the weakest crystal, the crystal least favorably disposed to stress, or the crystal bearing the greatest "internal strain," becomes loaded beyond its elastic limit.

What, then, goes on in hardened steel, which apparently has no elastic limit? It is a crystalline aggregate, and crystals are elastic. Experiments with the model indicate that when the crystals are stressed in all sorts of ways—some almost ready to split by tension imposed upon them by their neighbors, others working almost to their limit in compression, and the remainder with every intermediate amount—at the first increase of external load the worst-loaded crystal slips; with increasing loads more and more of the crystals less stressed initially reach their limit and slip, and so on. Plastic deformation (in part) starts from the beginning, and continues at an increasing rate. Hence, the model duplicates the stress-strain curve for hardened steel or copper. It has no straight beginning. But if the increase in load is at a moderate rate, is interrupted by rest periods, or if the day is pretty hot, the amorphous metal generated by the slips should recrystallize, and the overloaded crystals should heal, but now in the stress-free condition. Consequently, if the metal is then tested in tension, it should behave in an elastic manner as far as the previous fatigue load. And it does! By gradually increasing the fatigue load by steps—and this has also been proved by experiment—the metal can therefore be "fatigue hardened"—i.e., have all its crystals brought into the stress-free condition—and the fatigue limit would then be increased to correspond with the yield point, perhaps 20 to 30 per cent above the ordinary value.

Repeating the original heat-treatment spoils this gain, of course, for it puts into the metal the internally strained condition it had at the start. Here we pause for more information. It is easy to see how quenched alloy steel has severe internal strains, caused not only by volume changes due to differential thermal expansion, but also to partly finished transformations. But why should annealed copper?

That question can be answered by studying copper. At present we welcome the information given by these experiments. It is well known that the marine engineer brings up his engines by slow degrees and short trials, finally reaching full load. It helps run in the bearings of course, but, far more important, gives time and opportunity for the metal to slip into the unstrained condition. A proper start may add 20 per cent to the engine's strength.

Some mining companies buy crusher shafting by the carload, keeping spares on hand ready for the expected break (by "crystallization," as they call it). Starting off at full capacity, these machines are quickly and violently overloaded when cracking a big rock. Professor JENKIN'S model and the actual experiments it foreshadowed show that such usage will reduce the endurance limit 40 per cent of that when properly "fatigue hardened." Would it not be worth while to run these shafts in by short campaigns on carefully screened and sized rock?

Finally, spring manufacturers will do well to study the possibilities of the new method. Apparently in no class of steel is correct preparation by mechanical stressing more important than in heat-treated alloy steels. In fact, mechanical treatment appears to be as important as heat-treatment. And every one knows that automobile springs fail now and then.

Readers' Views and Comments

Dirt
In Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—The micrographs in the letter signed Martin Seyt in your issue of Jan. 24, showing inclusions in what was supposedly a tool steel and in an alloy steel shafting, although they served to emphasize the important bearing of inclusions on the quality of steel, seem to the writer rather unfortunate as examples, in that the polish was very poor and the magnification not stated. That these points are not trivial will be plain from the micrographs shown herewith.

The specimen from which the micrographs submitted were taken was a piece of rail steel (approximately 0.70 per cent C). The same spot is shown in all. However, the same inclusions are not shown in Figs. 1 and 2 as in Figs. 3 and 4, since the specimen was ground down somewhat after the quenching and previous to repolishing. For Figs. 1 and 2, the polishing of the specimen was purposely done incorrectly. One of the steps in the polishing procedure of the Bureau of Standards was omitted, the specimen being taken from the OF emery paper to the SF emery wet wheel (3F Alundum omitted) and after that polished for an insufficient time on the final alumina wheel. For Figs. 3 and 4, the sample was repolished correctly after being quenched from 800 deg. C. in water. The quenching is not essential, but it has proved advantageous at the bureau in similar examinations, since after the hardening the steel surrounding the inclusions is not so easily abraded away. The pit which invariably forms about each inclusion during polishing is then not very large and each inclusion is sharply outlined. Also the emery used in polishing does not become imbedded in the hardened steel as may occur in a soft steel and the particles of emery might be taken for inclusions.

Certainly an erroneous conclusion might be drawn by

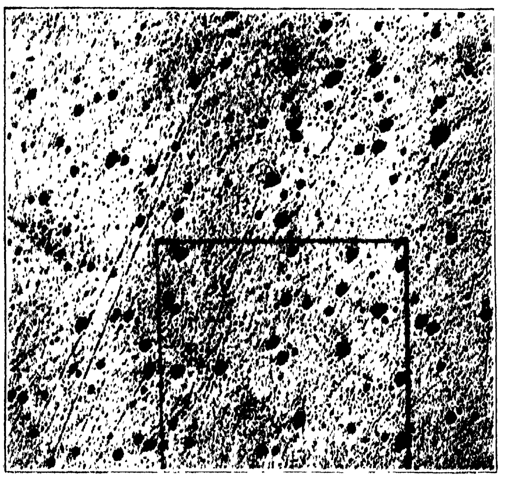

FIG 1—RAIL STEEL INCORRECTLY POLISHED × 50

FIG 2—SAME SPOT. × 100

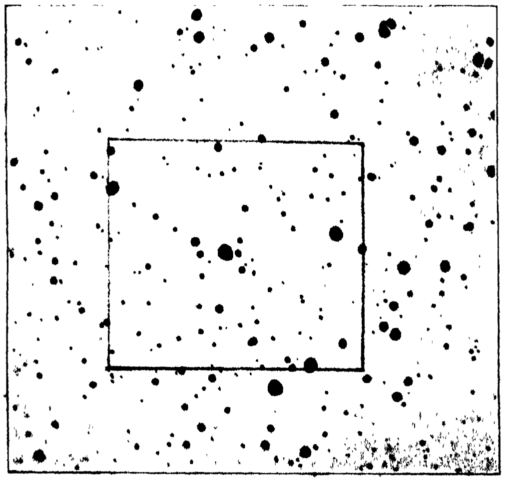

FIG. 3—SAMPLE QUENCHED AND REPOLISHED. × 50

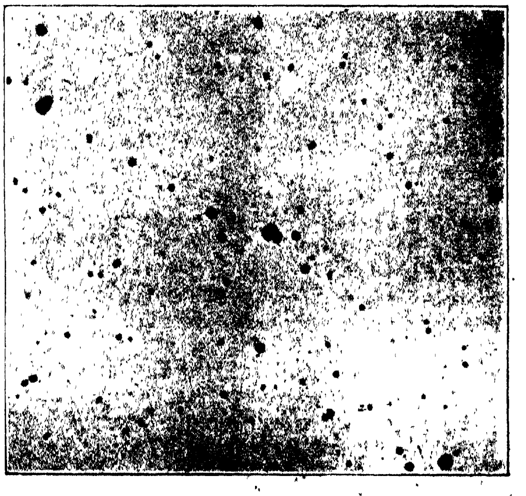

FIG. 4—SAME SPOT. × 100

judging the quality of the steel from the appearance of Fig. 1. In a cleaner steel and in a softer lower carbon steel, the difference between Figs. 1 and 2 and Figs. 3 and 4 could be even more striking. That it is necessary to state the magnification is evident if the appearance at 50 magnifications is compared with that at 100. in the same surface area there are four times as many inclusions at 50 magnifications as at 100. The area in the square at 50 magnifications makes up the whole micrograph at 100. The size of the inclusions appears almost the same at both; if anything, it is smaller at 100. This is an optical effect, a result of the slight pitting around the inclusions which cannot be avoided.

In metallographic examinations a study of the inclusions is of the utmost importance, and even more care should be used in the preparation of the specimen for observation of the unetched structure than for the examination of the structure as revealed by etching.

Shore Scleroscope

To the Editor of Chemical & Metallurgical Engineering

SIR:—Noticing your article on the new model scleroscope in your issue of Feb. 14, I am reminded of the fact that I met Mr. Shore somewhere in Brooklyn when he had just completed his first instrument. In conversation with him he gave me a few of his pamphlets and asked me if I could interest some business acquaintances, and he offered me a 15 per cent commission for selling the instrument. I perfectly recall the opposition I received from various men whom I talked with regarding this scleroscope; like everything new, they laughed at it and said it was of no use to them.

This is interesting, as I have learned that at Bridgeport they have reversed the principle and are testing the hardness of steel balls for roller bearings by bouncing them over a hurdle. I merely mention this as, perhaps, a note of interest to show the progression and growth of an idea.

GILBERT E. STECHER.
Weehawken, N. J.

Food Standards*

BY DR. W. W. SKINNER
Assistant Chief, Bureau of Chemistry

AN intelligent and effective enforcement of regulatory laws requires the formulation of definite standards. Standards would necessarily be developed but gradually and laboriously by precedent, by official fiat, or by specific legal enactment, were there no definite organization specifically constituted for the purpose, since a standard is, in many instances, the fundamental starting point in the determination of whether a food product conforms to the provisions of law. However, I believe there is quite prevalent a misconception of what a standard is or ought to be. This is because the word standard is an unfortunate one for our purpose, since the older and more common use of the word standard connotes superiority or a special mark of excellence. Thus, for instance, a standard meter stick or a standard pound weight indicates a unit of measure of unusual precision or accuracy.

A standard for a food product has quite a different significance, and indicates a limit or a point from which to measure. It is a zero point, as it were, above which products are acceptable if considering desirable constituents and below which they are to be rejected. Thus it is that a product which complies with a specification may be very much short of a really excellent or superior product—indeed, it may be as judged by popular conception a rather inferior product, yet comply with the standard specifications.

The recently issued and much discussed standard for milk bread well illustrates the point. The Joint Committee, after more than 2 years of consideration of the bread schedule, concluded that a bread made from a dough in which one-third of the usual water had been replaced by milk was entitled to be designated milk bread. I am not, I hope, violating any confidence when I express the opinon that probably every member of the committee personally prefers a bread with a higher content of milk solids than is represented by the use of one-third milk, and will welcome the opportunity to change the standard to include an additional amount of milk when the trade practice has been so improved as to make such a standard feasible. I cannot in brief limits attempt even a summary of the evidence which led the committee by a unanimous vote to define milk bread as noted above, and must be content with the assertion that the evidence was convincing to the committee that a consumer would have no reason to feel deceived or defrauded if sold a product as milk bread which conformed to these specifications.

The Food Standards Committee is a court where the evidence affecting a proposed schedule is carefully considered and where a judgment is rendered based upon the evidence presented. The administrative machinery of the committee has been developed to a point where it is believed we are getting the full evidence before the committee in the most effective way. Food officials, manufacturers, producers, distributors and consumers are given an opportunity to present their views and to criticise a proposed definition or standard.

The original Standards Committee with painstaking care and with a clearness of vision as to needs almost prophetic adopted certain principles as a guide for the action of the committee, and these principles unaltered are still the guide for the committee's action. A careful consideration of these principles will convince any one, I think, that it was not the conception of the members of the original committee or of the committees which have followed that it ever was or has been the function of the committee to erect or create arbitrary ideals and then attempt to translate such ideals into standards.

The three fundamental considerations which govern the committee in its deliberations and conclusions in formulating its definitions are:

(1) To define products so as to prevent unfair competition, since one effect of intelligently enforced regulatory food laws is the promotion of better business methods and better business ethics.

(2) To define products so that food officials may have a uniform and generally accepted guide in applying the general provisions of regulatory laws to commerce in food products.

(3) To define products so that the consumer may discern quality and exercise a discriminating choice, and that the producer may know and meet such a discriminating demand. In other words, to create a condition in the commerce of foods where vendor and vendee speak a common language.

*Statement in *Food and Drug Review*, the "house organ" of the Bureau of Chemistry, February, 1923.

Readers' Views and Comments

Dirt

In Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—The micrographs in the letter signed Martin Seyt in your issue of Jan. 24, showing inclusions in what was supposedly a tool steel and in an alloy steel shafting, although they served to emphasize the important bearing of inclusions on the quality of steel, seem to the writer rather unfortunate as examples, in that the polish was very poor and the magnification not stated. That these points are not trivial will be plain from the micrographs shown herewith.

The specimen from which the micrographs submitted were taken was a piece of rail steel (approximately 0.70 per cent C). The same spot is shown in all. However, the same inclusions are not shown in Figs. 1 and 2 as in Figs. 3 and 4, since the specimen was ground down somewhat after the quenching and previous to repolishing. For Figs. 1 and 2, the polishing of the specimen was purposely done incorrectly. One of the steps in the polishing procedure of the Bureau of Standards was omitted, the specimen being taken from the OF emery paper to the SF emery wet wheel (3F Alundum omitted) and after that polished for an insufficient time on the final alumina wheel. For Figs. 3 and 4, the sample was repolished correctly after being quenched from 800 deg. C. in water. The quenching is not essential, but it has proved advantageous at the bureau in similar examinations, since after the hardening the steel surrounding the inclusions is not so easily abraded away. The pit which invariably forms about each inclusion during polishing is then not very large and each inclusion is sharply outlined. Also the emery used in polishing does not become imbedded in the hardened steel as may occur in a soft steel and the particles of emery might be taken for inclusions.

Certainly an erroneous conclusion might be drawn by

Nichols Medal Awarded to Thomas Midgley, Jr.

Twentieth Anniversary of Original Presentation Goes to Engineer and Prominent Investigator in the Field of Gaseous Detonation—Address of Acceptance Reviews Anti-Knock Properties of Matter

BEFORE a notable assemblage of chemists in Rumford Hall, New York City, on March 9, the New York Section of the American Chemical Society awarded the Nichols medal to Thomas Midgley, Jr., chief engineer, fuel section, General Motors Research Corporation. The event marked the twentieth anniversary of the first presentation of the Nichols medal, which is awarded annually for the best original paper that had been published during the preceding year in any one of the three journals of the American Chemical Society. It was the unanimous judgment of the jury of award that this year the honor should go to Mr. Midgley's article on "The Chemical Control of Gaseous Detonation, With Particular Reference to the Internal Combustion Engine."

In his introductory remarks Dr. C. A. Browne, chairman of the New York Section, recalled that the medal had been established in 1902 through the generosity of Dr. William H. Nichols, past president of the American Chemical Society. The first presentation was just 20 years ago—in 1903. Under the original conditions the medal was awarded for the best paper given before the New York Section, but in 1913 the requirements were broadened to their present national scope. It was significant, Dr. Browne declared, that this year the award had been with the unanimous approval of the donors and had already received the popular assent of the chemical profession.

Midgley and His Work

"A mechanical engineer by education, yet one who quotes the periodic law freely and one for whom organic chemistry presents no terrors, such a man is Thomas Midgley, Jr.," said Professor Bancroft. "His career is the more extraordinary because he has thus upset all precedent."

Graduated from Cornell in 1911, thereafter employed until just prior to the war in connection with the rubber industry, Midgley's progress has been very rapid. Dr. Bancroft would attribute his success to his ability to correlate apparently meaningless and hopelessly scattered facts. He showed how from several different sources he has gathered together the disconnected fragments which first found expression in his working hypothesis and which have resulted in notable success in his work upon anti-knock mixtures.

Without knowing anything of the mechanism of reactions of mixtures undergoing combustion within fixed space limits, Midgley set out to study the rate of reaction under varying conditions and to analyze the phenomena of detonation in gaseous mixtures. Benzene and kerosene were used as fuel in these experiments. Investigation showed that the introduction of a foreign substance into the fuel mixture, even in minute amounts, would affect detonation, or knocking. Organic compounds of Se, Te, and especially of Pb, affected this property of knocking very appreciably. Tetra-ethyl lead entirely did away with the knock or detonation wave—in other words, the combustion of the fuel was complete before detonation occurred. A fraction of 1 per cent of these substances—as for instance, 0.04 per cent of $Pb(C_2H_5)_4$—in the fuel mixture completely eliminates the knock.

Dr. Bancroft pointed out that the significance of Midgley's work is to be far reaching. By decreasing the rate of reaction and thus allowing complete combustion of a fuel mixture, the compression is greatly increased. The saving effected means using much less fuel. In other words, Midgley's work may actually double the existing fuel supply. Unfortunately the existing type of motor in general use will not stand the compression required for the efficient use of anti-knock mixtures, and as a result the full value of the work done will not become apparent for some time.

In concluding his remarks Dr. Bancroft summarized the difficulties overcome by Midgley, commended him highly on the clear-cut manner in which his work has been carried out and congratulated him on the splendid success achieved.

Dr. Herty Presents Medal

Dr. Charles H. Herty, past-president of the New York Section, made the presentation. He called the roll of the distinguished investigators who have previously received the medal in order not only to demonstrate the esteem in which Midgley's work is held but also to emphasize the fact that his success has been attained at a comparatively early age. Best wishes for continued achievement on the part of the section attended the medal, Dr. Herty said, in making the presentation.

Acceptance and Address

In accepting the signal honor accorded him by the society, Mr. Midgley said that it was with a feeling of deepest humility that he recalled the names of the eminent investigators who were his predecessors as Nichols medalists. He asked, therefore, that he be allowed to receive the medal in the name of the organization represented by his faithful and industrious coworkers in the laboratories of the General Motors Research Corporation.

The acceptance address, entitled "Some Fundamental Relations Among the Elements and Compounds as Regards the Suppression of Gaseous Detonation," was

interpreted by Mr. Midgley in an informal discussion of the anti-knock characteristics of matter. At the outset he defined anti-knock as a property of matter whereby a material acts either as a negative or positive catalyst in the prevention of detonation in the internal combustion engine. This property is believed to be possessed by all of the elements provided the right compounds can be obtained. So far the investigations at Dayton have demonstrated that the property exists in the case of twenty-two elements and additions are constantly being made to the list. To be sure, certain compounds such as ethyl nitrite show the property in a negative sense and are referred to as negative catalysts, since they accelerate rather than suppress detonation.

The marked effect of the presence of a small percentage of diethyl selenide, one of the more important anti-knock materials, was demonstrated on the lecture platform by the combustion of a detonating mixture of acetylene and air. Tetraethyl lead, an even more powerful material, could not be used in this particular experiment because of its lower volatility.

THEORIES OF DETONATION

Mr. Midgley then reviewed certain of the theories which have been advanced in explanation of the detonation phenomena. He also showed the mathematical development of the equation generally accepted as an expression of the relation between the reaction velocity and the pressure in the wave of detonation. Those who were intertested in the thermodynamic phases of this subject were referred to Mr. Midgley's original publications in the *Journal of the Society of Automotive Engineers* and the *Journal of Industrial and Engineering Chemistry*.

In brief, the accepted theory of detonation is this: During normal combustion the differential between the pressure in the rear of the flame of propagation and the pressure in front of the flame is almost insignificant, its magnitude being less than 1 lb. per square inch. If, however, the flame front is caused to move forward at an extremely high velocity, as during detonating combustion, the pressure differential becomes enormous and the flame front is preceded by a region of dense gas at an extremely high pressure. The metallic sound, which we commonly call the knock, is caused by the impact of this high-pressure, high-velocity wave with the top and sides of the engine cylinder.

S[illegible]IFICANCE OF ATOMIC GROUPINGS

It has been [illegible] of these investigations to study a great many [illegible] particularly in relation to the influence of atomic groupings on the detonating effects obtained. The hypothesis has been advanced that the anti-knock property resides in the atom of the compound rather than in the compound as a whole. An example of the manner in which the groups modify the anti-knock property of the element is shown in the following table, which compares the relative effectiveness of three strong and one weak anti-knock elements with aniline as a standard of comparison.

The figures given are the reciprocals of the number of gram molecules required to give an anti-knock effect equivalent to that of 1 gram-mol. of aniline. The negative in the case of ethyl ether means, of course, that this compound accelerates detonation.

THOMAS MIDGLEY, JR.

Element	Derivative C_2H_5	Derivative C_6H_5
I	1.09	0.88
Se	6 9	5.2
Te	26.8	22.0
O	—0.046	0.122

A study of valence and bonding conditions in a wide variety of compounds has brought out a number of significant principles. The influence exerted on the detonating effects of the compound by the different atomic groupings was shown in a chart giving the anti-knock values of a number of elements when combined with hydrogen, alkyl and phenyl groups. Important studies have been made with the derivatives of carbon with the idea that the fuel itself may possess special anti-knocking properties. Starting with aniline (6C) and continuing with toluidine (7C), xylidine (8C), etc., it was found that the number of carbon atoms in the molecule bore a definite relation to the anti-detonation characteristics of the fuel and this relation could be plotted to yield smooth curves.

In concluding his address, Mr. Midgley stressed the fact that much more investigation was necessary to round out and complete the work on the chemical control of gaseous detonation. As is usually the case with pioneering in any field, the work of Midgley and his associates has blazed a trail through a fertile field of investigation. Others must follow. Many interesting problems are yet to be solved.

Important Gift to British Society

Sir Alfred Yarrow has presented $500,000 to the Royal Society for the promotion of scientific research, and in conveying his gift, records his conviction that a patriotic citizen cannot do better than give money for "the development of science, upon which the industrial success of the country so largely depends."

The Commercial Banker's Function In Business

An Interview with William Post, Chairman of the Executive Committee, Central National Bank of Philadelphia

BY CHARLES WADSWORTH, 3D
Assistant Editor of *Chemical & Metallurgical Engineering*

PERHAPS it was an unwarranted assumption that the engineer is almost completely unfamiliar with the practice and theory of commercial banking. If it was, we beg to assume the entire responsibility for it. During our interview Mr. Post was most patient in answering the questions which were asked, and the questions were those of a man without experience or contact with the field of commercial banking.

"When in Rome, Do as the Romans Do"

So runs the proverb, and it is sane advice, but inadequate. It makes no provision for finding out what the Romans do nor how they do it. Our suggestion would be to corral a wise Roman and get him to teach you what and how.

When we wanted to find out how a man or a corporation could borrow money from a bank to keep a chemical plant going, we went to a banker. Said he: "The subject of commercial credits is exceedingly intricate. By the way, have you read the 'Four C's of Commercial Credit,' by William Post? Well, you ought to read that first." Without more ado we took a train for Philadelphia and had a talk with Mr. Post. So it was we found our wise Roman.

For over 50 years he has been a banker, a human banker who will not reduce commercial credits to mathematics, and the substantial growth of the bank shows the wisdom of this course. He was one of the pioneers in credit analysis and his rich experience is projected for a fortunate community in his book. His spirit is a type of leaven which the business community needs.

Not unnaturally the first question had to do with the function of the commercial bank as far as industrial plants are concerned. In reply Mr. Post remarked that some, perhaps many, people believed that the commercial bank actually financed new ventures, supplying the necessary first capital for establishing a business. This of course can never be the case, as a brief consideration of the situation will show. The funds at the bank's disposal are funds deposited with it by its clients to be repaid upon demand—lodged with the bank for safe keeping.

Of course, good banking practice as well as government regulations provide that a definite cash reserve on deposit be maintained. The remainder of the money on deposit is available for loans and other investment. But let us assume that a bank were permitted to make loans on long-time credit or even to contribute a part of a capital investment. What would happen? For one thing, a certain part of the loans made as capital investment would be lost in new ventures, because of unforeseeable risks. In other words, part of the depositors' money would be gone or the bank's working capital impaired. The risk in such investment is no part of commercial banking. Similarly during the life of a long-term credit loan it is possible for conditions so to change that the lender bank would find it necessary to liquidate its investments because of an imperative demand for cash. So it is the result of seasoned experience to place a time limit on commercial credits, which is usually from 90 days to 4 months and should not even in exceptional examples exceed 6 months.

Thus it will be seen that contrary to a widespread impression a commercial bank does not and should not play any part in the establishment of industrial enterprises. An inventor or engineer who has an idea and no money must not expect a bank to finance him. The original capital should come from investment channels—individuals or stockholders.

A bank may begin to assist an enterprise after it has been successfully started and it should and will continue its assistance and support as long as the business remains healthy, vigorous and honest. Sometimes it is necessary for banks to stick by old clients when they are in a tight place. This will be to protect a good client unavoidably drawn into a rather hard situation, or to protect loans already made. Except for such instances a commercial bank must confine itself to liquid business; it is in no sense a doctor for sick business, though it will foster and aid new business up to a safe point.

What, then, are the criteria developed for evaluating a business from the banker's standpoint? How shall the banker decide to grant or not to grant a loan?

This, Mr. Post remarked, is the whole problem of commercial banking in a nutshell. In such an interview as this it is possible only to indicate the kind of estimate which the banker must make. To develop the subject adequately would require a volume, and even then the text would be colorless. Commercial credit is a problem of individual cases and only the most flexible type of generalization can be made. The variables are many and any effort to reduce the problem to rigid mathematical determination will result in unsafe banking. Woe betide the banker who looks only at the financial statements of an enterprise without full knowledge of the men behind the statement, for

financial statements are only as dependable as their authors.

The banker looks for three things in a prospective borrower. They are Character, Capacity and Capital. These, with the fourth "C"—Collateral—are the four big factors to be considered in extending bank credit. Capacity alone is distinctly a dangerous prospect, for an unscrupulous operator with plenty of ability, though he may pay bills as a matter of policy until a pinch comes, may then not hesitate to conceal quick assets and leave the creditors a meager skeleton to pluck. So too Character alone would frequently be unable to meet his debts—and Capital unsupported by Character and Capacity finds himself a mendicant more frequently than not.

If Character and Capacity be linked, the banker has a very fair prospect. When supported by these, even limited capital may satisfy the banker that his support is merited. The mathematical banker may shake his head and say "No" when a more human confrère will win a lifelong friend and a strong account for his bank by encouraging a loan to the comparatively new business, accompanied by modest capital. Let Capital be linked with Character and Capacity and the combination can be beaten only by the addition of undoubted Collateral to the group, in which case the commercial loan should be most secure.

Collateral a Quicksand

Before discussing a few of the significant phases more specifically it should be remarked that collateral is a quicksand which it is necessary to scrutinize with experience and care. Collateral loans are much sought after by banks, and yet it is probable that more losses result from them than from straight single name paper. The reason for this seems to be that collateral loans are made up on many types of collateral—nor are they watched with as great care as other loans. The collateral is taken in at a desirable margin, but the bank often neglects to check the intrinsic worth in the collateral or to note its fluctuations and keep margins built up.

The problem is by no means solved by referring to the four C's of commercial credit. It is merely defined. The classification enables us to think more clearly and with a proper balance, unconfused by the complexity of the subject. The technique of evaluating character, capacity, capital and collateral must be elaborated in a more comprehensive way than an interview will permit. Let me illustrate, however, the method of approach. Capital is variously listed depending both on the type of organization and the attitude of the author of the financial statements. A banker must analyze the statement with both those things in mind. Some firms will capitalize intangible assets such as good will, patents, trademarks and the like; some business houses write down the values of fixed assets such as land, buildings and machinery in a conservative way that will be desirable. In some corporations common stock represents real value, in others it will be tucked in to make resources and liabilities match. These are but a few of the questions to be answered on this one point.

Again, a proposition must be in bankable shape to receive commercial credit. This means among other things that the quick or liquid assets, which include cash on hand or on deposit, bills and accounts receivable and merchandise, should be approximately twice as great as the quick liabilities. This so-called 2 to 1 ratio is perhaps the most widely recognized and practiced generalization in commercial loaning by banks. Naturally it is not rigid and during the war period and days of readjustment it had to be abandoned. Honest customers operating largely upon government orders had to be aided regardless of the ratio of their assets and liabilities. Then, as in the past, banks had need to violate conservative practices. Thus it is that the commercial banker works. He must be a constructionist aiding worthy enterprises with his every resource. For so he will prosper as an integral part of the community.

Mineral Production in Ontario

Abstract of an Address by Canadian Bureau of Mines Head With Particular Emphasis on Nickel and Iron

While addressing the Engineering Institute of Canada in Ottawa recently, John McLeish, director of the Department of Mines, Canada, stated that a very large proportion of the important minerals of commercial value in Canada are to be found in the Province of Ontario. The nickel deposits at Sudbury supply over 80 per cent of the world's demand. They also possess very large ore resources and are at present sufficiently developed to maintain the present industry for more than 100 years. Favorable results have already been obtained in the demonstration of new uses for nickel. The question at present under consideration is the development of a market to replace that which armor plate formerly provided.

The total value of mineral production in Ontario increased from approximately 15 millions in 1902 to more than 25 millions in 1906, and in 1913 amounted to nearly 60 millions. Through increased production and high prices, a value of 95 millions was reached in 1918 or approximately 45 per cent of the total value of the production for all Canada. In 1919, the first year following the war, production dropped to 68 millions, rose the next year to nearly 82 millions, dropped in 1921 to 54 millions and is again on the up grade, having reached about 65 millions in 1922.

Turning to the iron situation, Ontario has not, as yet been able to develop a successful and continuous ore industry. Ores of merchantable grade in the natural state have not been available in large quantities. There are, nevertheless, large resources in low-grade ores, principally magnetite and siderite, which should be put into commercial form. The most serious attempts have been on the siderite ores at Magpie and the magnetites at Sellwood, north of Sudbury. Both of these have been successful in producing an excellent furnace product but the cost is still too high to justify continued commercial operations.

Constancy of Platinum Thermocouples

Life tests of the pure platinum and platinum-rhodium wire prepared at the Bureau of Standards for thermo-couples have been carried out by the heat division. These tests are the same as those applied to commercial couples which were recently reported by Fairchild and Schmitt in *Chem. & Met.*, Jan. 25, 1922 (vol. 26, p. 158). Results thus far obtained indicate that couples of material purified, melted, and drawn to wire at the bureau are appreciably superior to the best commercial couples previously tested.

Industrial Importance of the Metallic Soaps

Striking Properties of These Relatively Unfamiliar Substances Indicate a Wide Range of Commercial Applications

BY HILTON IRA JONES

Director of Research, Redpath Bureau, Redpath Laboratories, Wilmette, Ill

AUTHOR'S NOTE: This work was originally begun in 1910 in connection with a problem for the American Kellystone Co. on the waterproofing of its products. It was again resumed in 1918 in connection with the work of Robert DuBois for his Master's degree. It was at this time directed toward the preservation of eggs (see *Journal of Industrial and Engineering Chemistry*, August, 1920). It was continued during 1919-1921 as a part of the work of Gladys Trevithick for her Master of Science degree. During the past year it has been carried further as a part of our work on the waterproofing and mildew-proofing of canvas for the Redpath Bureau.

METALLIC soaps, as the term is used in this article, refer to the stearic, palmitic, oleic and hydrogenated-oil soaps of magnesium, copper, aluminum, zinc, lead, nickel, calcium, cadmium, antimony, strontium, tin, cobalt, barium, iron (ferrous and ferric), silver, mercury (-ous and -ic), arsenic, chromium, bismuth, magnesium, ammonium and lithium, all of which have been prepared and systematically studied. The water-soluble soaps of the alkali metals are not included in this classification.

Although these materials are not familiar articles of commerce, they are nevertheless important products from an industrial viewpoint. Their actual as well as potential uses cover a wide range of industries. They find a large market in the manufacture of lubricating greases. Another important use is in paint and varnish as driers. One of the greatest present and potential uses of the metallic soaps is in the waterproofing of cloth. Minor uses are found in disinfectants, in medicine, in taxidermy and in dry cleaning. More detailed reference to the industrial applications of the metallic soaps will be found elsewhere in this article.

PREPARATION ON THE CLOTH

Most metallic soaps, because of their great insolubility in water, are prepared by precipitation. A warm water solution of the alkali soap of the desired acid is added to a water solution of the salt of the desired metal, and the precipitate of the metallic soap is pressed dry and later dissolved; or else the material to be waterproofed is impregnated first with the one solution and then the other, thus precipitating the metallic soap within the pores of the object. One of the large tent companies formerly treated all its canvas in this way. This is a less efficient and desirable method for reasons presently to be shown. Often the aluminum soaps are precipitated within the fiber of cloth, especially canvas, by an electrolytic process. In this process the cloth is passed through a warm bath of the soap, squeezed out between pinch rolls, and passed directly into the "electric bath," where it runs between aluminum electrodes. The precipitating aluminum hydroxide combines with the soap in the cloth, thus precipitating the aluminum soap in the fiber.

METALLIC SOAP "SOLUTIONS"

While we speak of a soap's "solubility," it is doubtful if any soap ever forms a true solution. The solutions are apparently in all cases colloidal emulsions. The alkali soaps, however, form with water what generally pass for true solutions. The presence of many oils, such as kerosene, gasoline, paraffine and the like, often even in very small amounts, produces a great increase in the fineness of the colloidal aggregate. This fact explains, of course, the added cleaning and detergent power possessed by soap in case some of these oils are added—hence the "naphtha soaps" and the score of washing compounds, which are mainly paraffine plus, say, a little ultramarine. The surface tension is also raised as the colloidal aggregate becomes finer. Indeed, the colloidal dispersion and the surface tension bear, it seems, a definite relation to each other.

Most dry metallic soaps—for example, aluminum stearate—are as insoluble in gasoline, alcohol, chloroform and the like as they are in water. The freshly prepared wet soap is readily soluble. If once the soap is dried, the colloidality is destroyed and water cannot easily again be incorporated with it. The solution in the other paraffine oils works the same as gasoline. It is remarkable the amount of water these oil emulsions of the metallic soaps will "take up." They are much like lanolin in this respect. This solution of the metallic soaps has always presented difficulties. Often "smooth" solutions will be obtained, and then again they will settle out. In fact, the published directions for using such commercial solutions as are on the market seem to take it for granted they will be colloidal failures and settle. So they admonish the consumer to "shake or stir thoroughly." The making of solutions of metallic soaps is the old problem of mayonnaise dressing. The trick is to get the true colloidal state, and the second is to keep it so. The temperature of the precipitation seems to be an important factor. Below a certain critical temperature, for example, copper stearate comes down as a non-colloidal granular mass. But when freshly precipitated from a hot solution above this critical temperature (as it should be), it is tremendously sticky, and reminds one of chewing gum. Cold, it is a hard, brittle wax, similar to molasses candy. This wax is readily soluble in gasoline and other paraffine oils to form a mucilaginous, colloidal solution, which can be kept indefinitely without settling. Many substances, of course, like acids, and conditions, like freezing, will break the colloid and make the soap settle out. In the formation of such a solution, the water is as essential as the oil.

STABILIZING EFFECT OF ADDED WAX

It has been found that the addition of colloid waxes, such as lanolin or beeswax, has a remarkable stabilizing effect on the colloid. Such solutions may be evaporated and the wax heated to 45 deg. C. for weeks without the colloid being in any way affected. Pure sugars crystallize readily from pure solvents. A mixture of sugars crystallizes with difficulty, especially if impure. So a mixture of colloids is more stable than a single pure one. This fact is of the greatest importance, since the usefulness of the metallic soaps depends largely upon their being maintained in colloidal condition.

The pure metallic palmitates and stearates are almost impossible to maintain as colloids without the addition of one of these waxes. This fact explains why their use has been so often disappointing. On the other hand, the oleates are generally so soft as to render the finished product, say canvas, sticky and they also tend to turn rancid with age. We have found that the use of hydrogenated-oil soaps seems to solve both difficulties. There seems to be no single hydrocarbon solvent in which the dry metallic soaps are soluble. They are all soluble whe

wet and freshly prepared by precipitation. But the best solvents vary with the metal and the acid. Commercial lead soap with linoleic acid goes into solution easily in almost all hot petroleum solvents and comes out again from the cooled solvent almost completely within an hour. The nickel soaps separate out in several days. The ferrous iron soaps go into solution easily and come out again in a few hours increased in weight (due to oxidation). The ferric soaps are much more insoluble. Wet aluminum soaps are soluble in gasoline, turpentine and benzene. The oleates of calcium, magnesium and iron dissolve readily in glycerine. The ammonium soaps are all very soluble in water. Lead, magnesium and copper soaps, if wet, are soluble in alcohol and ether. Zinc oleate is soluble in carbon bisulphide, etc.

The literature on the solubility of the numerous metallic soaps is chaotic and unreliable because the colloidal character and the part played by the water and other factors have not been recognized. For example, one author states that "aluminum soap is very insoluble in nearly all solvents." This is true only if it has been allowed to dry. The wet freshly prepared soap is readily soluble in several solvents. The addition of a little colloidal wax, as lanolin, will completely alter the solubility. The whole matter of preparing these colloidal emulsions of the metallic soaps is complex and not well understood.

Colloidal Properties

The same chaotic state seems even more pronounced when we examine the literature relative to the properties of these metallic soap solutions. This is probably because their colloidal character has not always been recognized. Moreover, the characteristics of such colloids have been little known, but much has been surmised. Their properties are due, it seems, somehow to the extreme fineness of the particles in suspension. These conditions vary within wide limitations, but in a general way this condition apparently begins with dimensions somewhat smaller than the wave length of light and extends downward well into such dimensions as theory ascribes to the molecules of crystalloids. Such solutions are micro-heterogeneous systems distinguished from true solutions of molecules or ions by the possession of surfaces of contact with all the properties implied by this. These properties will naturally be very marked because of the enormous surface provided by the minute state of subdivision. These enormous surfaces provided enable such colloids to adsorb in the interface a great variety of substances and these often in surprising amount. Always the substance used to produce this dispersion, which for lack of a better term Graham called a "peptizing agent," will be most adsorbed. This in the case of these metallic soaps is nearly always water. This explains the unusual waterproofing character of these soap colloids and makes plain why they must be maintained on the fiber in colloidal state. As the soap-impregnated fiber is wetted a swelling takes place—exactly analogous to the swelling of gelatine in water, and the pores of the fiber are absolutely sealed. Extremes of heat and dry air, and especially high concentrations of the violet and ultra-violet light rays, such as we get in New Mexico and Arizona, for example, all tend to destroy the colloidal properties of the soaps in the canvas, which then gradually dust out and are carried away by the continual beating of the wind. Thus the metallic soaps precipitated directly on the fiber, as in the double dip or "electric process," are soon lost and made valueless. Those prepared with the addition of colloidal waxes as mentioned are more stable.

These colloids will also take up all manner of perfumes, essential oils, dyes and pigments, and in fact anything soluble either in the water or the oil. They will adsorb many things soluble in neither, especially if the material is colloidal. They form, consequently, an ideal vehicle for medicinal salves, plasters and ointments. These facts might well lead to several valuable changes in the present pharmacopea—e.g., the substitution of colloidal zinc soap for the ordinary powdered zinc stearate. Their tremendous surface tension makes them great detergents. They will be incorporated as a part of many soaps when these facts are realized. Sufficient sodium tungstate may be incorporated with these metallic soap colloids so that the canvas is fireproof as well as waterproof.

The efficacy of many drugs and poisons appears to depend upon the fineness of the subdivision—that is, the exposed surface area. This suggests the use of these colloidal metallic soaps in all manner of sprays, in fungicides—e.g., copper soaps—medicines, as colloidal mercury and the like. We have found that extraordinarily small amounts of colloidal copper soap will produce unexpected protective effects against mildew and the like.

These striking effects of the metallic soaps that lend them so well to a multitude of uses provide their own undoing in one case. There are certain colloidal clays, like the Denver mud and fullers earth, as is used in petroleum refining, which have, as is well known, great adsorbing powers, especially for colloidal substances which they thus tend to remove from the more crystalloidal (less colloidal) sugars, oils, etc. When a metallic soap-protected canvas is unrolled and rolled up again on a wet clayey ground, the clay is obviously pressed into the very fiber of the canvas and there it adsorbs the colloidal soap and entirely removes it from the cloth. The very properties which make the soap valuable as a waterproofing and mildew-proofing substance facilitate its removal by the clay. No method of preventing this action of these clays has come to light.

As we can obtain supersaturated solutions of crystalloids and small additions of certain substances tend to increase this possible supersaturation disproportionally, so there appears to be no definite solubility in respect to colloidal suspensions. The finer the state of subdivision the more will dissolve, the more stable the colloid will be and the greater will be the surface tension, as well as the detergent and adsorbing power. Such stabilizers are now generally called "protective colloids," because they protect the colloidal particles from separating out. They are themselves generally colloidal.

Industrial Applications

Lubricating Greases. The properties of these various metallic soaps have already caused them to be put to a great number of practical uses. The use in greases is one of the best known. The greases on the market may be divided into four main groups:

1. Greases with alkali soaps used as hardeners.
2. Greases made with fatty oil and lime soaps.
3. Greases with both alkali and lime soap.
4. Greases made with rosin oil and lime soaps.

These vary greatly in composition and kind. They contain anywhere from 5 to 50 per cent of soap and by varying the proportions of soap and filler, greases of any desired consistency can be made. Zinc, aluminum, magnesium and lead soaps are also used in greases and lubricating oils. Lead soaps are especially used in a class of lubricants known as "anti-friction greases." Lead soaps are hard at low temperatures, viscous at ordinary temperatures, but sufficiently fluid under the heat of friction.

Paint and Varnish Driers. Another great present-day use of metallic soaps is in paints and varnishes as driers. Lead and manganese oleates are mostly used. The former is made by saponifying litharge with olive or cottonseed oil; the latter by the direct action of manganese carbonate on oleic acid. The enormous surface obtained by using these colloidal soaps of the metals explains their effectiveness. In case high temperatures are used in hastening the oxidations, the varnishes are spoken of as baking japans. The ordinary linoleates, and resinates of lead and manganese, which form the basis of so-called driers, act by catalysis causing a rapid oxidation of the oil or varnish to which they are added. Lead and manganese form both a lower and a higher oxide which readily pass from one to the other. When present in the film in the higher state of oxidation they give up half their oxygen to the oil, then take up more from the air and so act continuously as catalytic agents to pass along oxygen from air to oil. In this the manganese soaps are more active than the lead. Other metallic soaps such as nickel and cobalt, which readily change from one state of oxidation to another, may be used in these driers, but they appear to have no advantage over the lead and manganese compounds. It is remarkable the catalytic effect produced by minute traces of these metallic colloids. With less than one-tenth of 1 per cent, the effects are very marked. The greatest danger is the use of too much, since it is likely to continue to act slowly even after the film has hardened and so in time to destroy the strength and elasticity. Such driers are generally not used in spirit varnishes nor baking japans.

Waterproofing. The waterproofing of objects by means of the metallic soaps furnishes one of its greatest present and potential uses. The use in waterproofing of cloth has already been mentioned. Our process for sealing eggs with colloidal solutions of aluminum soap has already been published. We are now working on similar processes for preserving fruits and vegetables. Most attempts at waterproofing cements and the like have depended upon the direct precipitation. This has generally resulted unsatisfactorily because of the tendency of the precipitate to lose its colloidal character. This is especially noticeable in case of the aluminum soaps precipitated in concrete, and the magnesium oxychloride cements. We have found that the use of protective colloids tends to prevent this loss of colloidality. By similar solutions coupled with protective colloids we have obtained excellent results in the weatherproofing and rustproofing of iron. Such solutions form an ideal vehicle for aluminum and bronze powders and also various oxides.

Medicines. Dzevagoviskii and Stepanova[1] have studied the disinfecting power of naphthalic acid, cresolated and formaldehyde soaps. We have found that the germicidal power of such soaps is much surpassed by the incorporation into ordinary soap of colloidal mercury oleate. These colloidal organic compounds of mercury are much to be preferred to inorganic mercurials, as they are not injurious to the skin. Similar colloidal copper soaps have unexpected fungicidal properties. Vermorel and Dantory[2] have written of these.

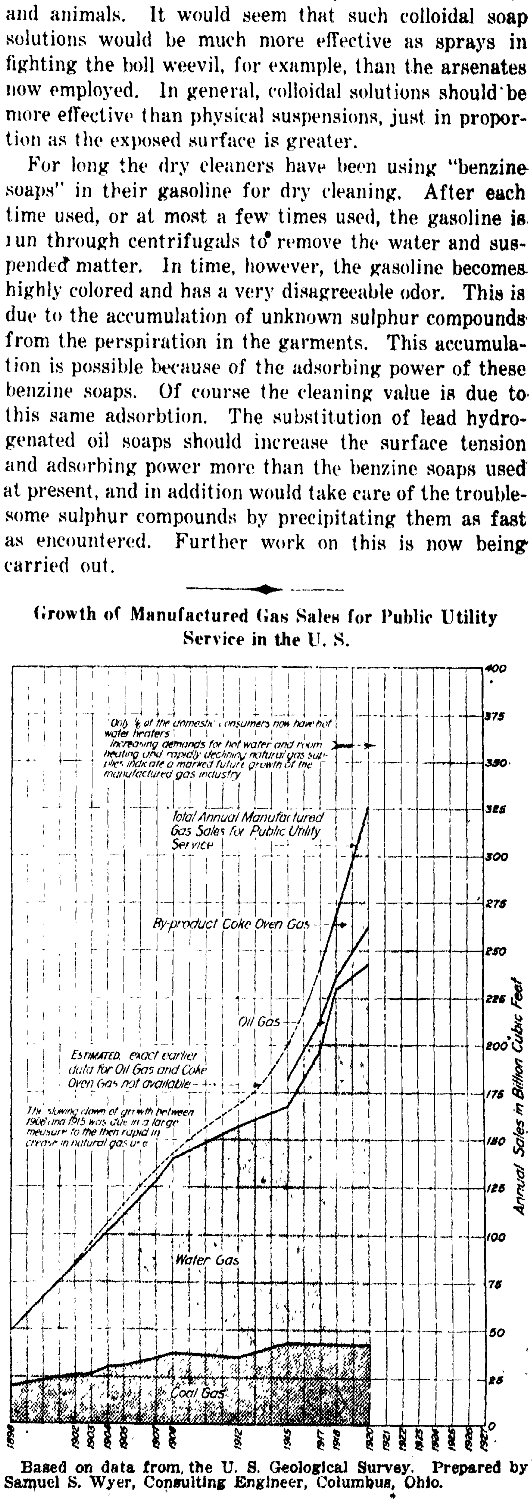
Most metallic soaps will dissolve in both the alcohol (glycerine) or the fatty acid. Such solutions of the calcium and iron soaps are valuable in medicine for lime insufficiency, especially in the case of nursing mothers and in anemics. They would be more widely used if the value of colloidal drugs were generally realized.

Miscellaneous. In laundering the formation in the fabric of insoluble soap precipitates, especially of iron, causes a marked deterioration in the strength of the cloth.

Arsenite soaps containing camphor have long been used by taxidermists in preserving the skins of birds and animals. It would seem that such colloidal soap solutions would be much more effective as sprays in fighting the boll weevil, for example, than the arsenates now employed. In general, colloidal solutions should be more effective than physical suspensions, just in proportion as the exposed surface is greater.

For long the dry cleaners have been using "benzine soaps" in their gasoline for dry cleaning. After each time used, or at most a few times used, the gasoline is run through centrifugals to remove the water and suspended matter. In time, however, the gasoline becomes highly colored and has a very disagreeable odor. This is due to the accumulation of unknown sulphur compounds from the perspiration in the garments. This accumulation is possible because of the adsorbing power of these benzine soaps. Of course the cleaning value is due to this same adsorbtion. The substitution of lead hydrogenated oil soaps should increase the surface tension and adsorbing power more than the benzine soaps used at present, and in addition would take care of the troublesome sulphur compounds by precipitating them as fast as encountered. Further work on this is now being carried out.

Growth of Manufactured Gas Sales for Public Utility Service in the U. S.



Based on data from the U. S. Geological Survey. Prepared by Samuel S. Wyer, Consulting Engineer, Columbus, Ohio.

Modern Methods for Making Cupola Mixtures

Diagrams Are Useful to Determine Amounts of Available Pig Iron to Weigh Into Mixture in Order to Secure Castings of Required Composition — Silicon and Manganese May Both Be Easily Predetermined if Three Piles of Pig Iron Are in the Yard

BY H. L. CAMPBELL
Assistant Professor of Metallurgical Engineering,
University of Michigan

OF the many factors which contribute to the economic production of iron castings, one of the most important is the proper proportioning of the metal mixtures used in the foundry. As the prices of raw metals are based largely on their compositions, it is imperative that the most economical mixtures of metals be used. The price of pig iron is dependent upon the elementary constituents in the metal. As the silicon and manganese contents increase or the sulphur and phosphorus contents decrease, the price advances. Likewise, scrap metals are sorted into groups according to the previous uses of the metal parts; which is indirectly a classification based on the composition of the metals. The cost of any ferro-alloy is determined on the basis of its important elementary constituents. Since these materials are purchased as chemical compounds, their true values will be obtained only when they are used as chemical compounds and mixed so as to produce the desired analysis in the product.

It is recorded by Thomas D. West that previous to 1890 practically all of the foundries in the United States had purchased pig iron on the basis of the appearance of the fractured surfaces of the metal. The metal with the most open grain structure was used for the softest castings and the close-grained iron was melted for hard castings. The practice of using the "fracture grading" method in preparing cupola charges led to many foundry troubles and unreliable properties in the castings. The foundry industry has been slow in adopting the practice of mixing metals by analysis and even today there are foundries where little attention is given to proportioning the metal mixtures used in cupola charges.

One of the important demands on iron castings today is uniformity in hardness. This requirement has resulted from the modern practice of rapid production in the machine shop. Machine tools are equipped for multiple operations and if castings of non-uniform hardness are machined, the adjustments of the tools will not remain fixed and a delay in production and inaccuracies will result. It is not uncommon to find an industry paying a premium for castings with uniform machinability. This condition may be obtained by controlling definitely the metal mixtures for the cupola so as to obtain a uniform composition which will result in uniform physical properties in the castings.

As the physical properties of the metals are dependent upon their chemical compositions, definite compositions may be established for castings for specific uses. The service requirements of gears, grate bars, stove plate, steam cylinders, car wheels and sash weights are entirely different and therefore the analysis of the metal used in each of these types of castings should be different. The limits or range of composition of the castings to be produced must be established first. Then the proportions of scrap metals and pig iron for the metal charges must be determined.

The Use of Scrap Metals

The results of experience and a knowledge of the compositions produced after melting will enable a foundryman to decide upon the pig iron and scrap proportions suitable for a given type of castings. The relative amounts of pig iron and scrap which will produce solid castings that will pass rigid inspection should be used. From 0 to 100 per cent scrap iron may be used in the metal charges for the cupola. Castings produced from all-scrap mixtures are generally hard and of inferior quality. The average practice is to use from 40 to 60 per cent of selected iron scrap in the metal charges.

In every foundry a certain proportion of the metal poured is returned to the cupola to be remelted in later charges. This scrap, which is sometimes called "home scrap" or "returned foundry scrap," consists of defective castings and sprues from previous heats. The amount of this scrap varies from 25 to 50 per cent of the total metal poured.

In addition to the returned foundry scrap, it is generally necessary to purchase some iron scrap from outside sources. Also, it may be desired to use some steel scrap in the charges for certain types of castings. There is an advantage in obtaining uniform grades of purchased scrap. The composition of the returned foundry scrap will be approximately the same as the castings produced. It is necessary to estimate or actually determine the average analysis of the purchased iron and steel scrap. This information is required when figuring the metal charges.

Changes in Composition Due to Melting in Cupola

Before the amounts of the components in a metal charge can be computed it is necessary to determine the effect of the melting process on the elements in the metal charges. The change in composition of the metal mixture before and after melting will depend largely upon the practice of melting; and for a given installation and a definite practice this variation in composition will remain the same for all heats. By using mixtures of known composition and analyzing the resulting cast metal, the effect of cupola melting on the elements in the charges may be established.

Silicon is partly oxidized in the cupola and the loss is about 10 per cent of the silicon in the metal mixture. Therefore an excess of silicon will be required in the metal charged over the amount specified in the castings.

The manganese content of the metal mixture is also decreased during the melting of the metal in the cupola. A manganese loss of 15 per cent of the original manganese content is generally assumed.

The sulphur content of the metal is increased upon remelting, as the metal takes up sulphur from the fuel. The metal gains in sulphur about 0.02 per cent when melted with coke containing less than 0.75 per cent sulphur.

The action of the remelting process as related to phosphorus is mainly that of concentration, although coke contains about 0.01 per cent phosphorus, which may be dissolved in part by the metal. Phosphorus and sulphur are not oxidized during the melting process, but may be removed from the metal to some extent by the slag. If the average phosphorus content of the metal mixture is below 0.80 per cent, an increase of 0.02 per cent phosphorus in the metal may be used in computing metal mixtures. While it is possible to assume certain changes in the elementary content of the metal charges during melting, it is better practice to determine these factors experimentally for a given cupola practice.

The raw metals are generally procured within the maximum limits of the sulphur and phosphorus requirements of the castings produced. The desired manganese content may be obtained by proportioning the metal charges or by the addition of manganese to the molten metal. The pronounced influence of silicon on the properties of cast iron warrants the practice of using this element as the determining factor in calculating metal mixtures.

After establishing the analysis of the castings, the scrap proportion and the changes incurred in melting, it is possible to determine the exact amounts of the components in each metal charge. In order to illustrate specific methods for making metal mixtures, some hypothetical compositions are used.

The desired analysis of castings and the compositions of pig iron and scrap metals available are given in Table I.

As 10 per cent of the silicon in the total metal mixture is lost in melting, the average silicon required in the metal mixture is found by dividing 1.80 per cent by 0.90 (1.00 minus 0.10), which gives 2.00 per cent silicon in the metals charged into the cupola. The average manganese content of the total metal mixture is obtained by dividing 0.70 per cent by 0.85. The sulphur and phosphorus increase during the melting process, but not in direct proportion to the amounts of these elements in the raw metals. Sulphur increases 0.02 per cent. Therefore the average sulphur content of the total metal mixture is found by subtracting 0.02 per cent from the maximum sulphur content of the castings. The percentage of phosphorus is arrived at by subtracting 0.02 per cent from 0.50 per cent.

A proportion of 50 per cent pig iron and 50 per cent scrap iron is assumed in the charges figured here by way of illustration. Of the total scrap, three-fifths is returned foundry scrap (30 per cent of total mixture), which will have approximately the same analysis as the castings, and two-fifths is purchased scrap (20 per cent of total mixture), which consists of machinery castings. The average analysis of the scrap is found by adding three-fifths of the foundry scrap analysis to two-fifths of purchased scrap analysis.

The average composition of the pig iron mixture may be found by multiplying the average composition of the scrap by its percentage, subtracting this product from 100 times the composition of the total metal mixture charged and then dividing by the percentage of the pig iron used.

$$\frac{(100 \times 2.00) - (1.74 \times 50)}{50} = 2.26 \text{ per cent silicon in pig iron mixture.}$$

$$\frac{(100 \times 0.82) - (0.70 \times 50)}{50} = 0.94 \text{ per cent manganese in pig iron mixture.}$$

As the combined pig iron mixture must average 2.26 per cent silicon, it will be necessary to mix two lots of pig iron with silicon contents above and below this amount. If piles A and B are used, it will be necessary to find the exact amount of metal from each of these piles for one metal charge. The pig iron mixture may be determined by the use of algebra or the application of a simple formula or by a graphical method.

Let M = pounds of metal in one charge.
Let X = pounds of metal from pile A
Then $(M - X)$ = pounds of metal from pile B.
The total silicon in the mixture equals the sum of silicon from piles A and B.

$$(M \times 2.26) = (X \times 2.83) + (M - X) \times 1.34$$
$$2.26M = 2.83X + 1.34M - 1.34X$$
$$0.92M = 1.49X$$
$$\frac{0.92M}{1.49} = X = 0.62M \text{ lb. of metal from pile A.}$$
$$\text{and} \quad \frac{0.57M}{1.49} = 0.38M \text{ lb of metal from pile } B.$$

By the method given above, the proportions of the two piles of pig iron which will produce the exact silicon content in the mixture will be derived. The manganese, sulphur and phosphorus contents of the mixture may be obtained by multiplying the proportions of the two piles of pig iron by the amounts of their elementary constituents.

The Use of Formulas in Making Metal Mixtures

$(0.62 \times 0.96) + (0.38 \times 0.98) = 0.97$ per cent manganese in mixture.

$(0.62 \times 0.04) + (0.38 \times 0.03) = 0.036$ per cent sulphur in mixture.

$(0.62 \times 0.40) + (0.38 \times 0.38) = 0.39$ per cent phosphorus in mixture.

The proportions of metal from two piles of pig iron which will give the desired silicon content in the mixture may be derived by the use of formulas.

Let L = per cent silicon in low-silicon pig iron.
Let H = per cent silicon in high-silicon pig iron.
Let D = per cent silicon desired.

If piles A and B are used, then according to the equations derived in the previous algebraic problem:

$$\frac{D-L}{H-L} = \frac{2.26-1.34}{2.83-1.34} = \frac{0.92}{1.49} = 62 \text{ per cent} = \text{ratio of metal in one charge from high silicon pig iron, pile } A.$$

$$\frac{H-D}{H-L} = \frac{2.83-2.26}{2.83-1.34} = \frac{0.57}{1.49} = 38 \text{ per cent} = \text{ratio of metal in one charge from low silicon pig iron, pile } B.$$

Graphical Methods for Determining Metal Mixtures

A graphical method for determining the proportions of high- and low-silicon pig iron in a mixture having a desired silicon content may be applied as follows: Use piles A and B with the analysis of the pig iron mixture as given in Table I. Refer to Fig. 1 for graphical solution.

First, lay off in any convenient scale, on a base line, the amount of percentage of metal in one charge.

TABLE I

	Silicon, Per Cent	Manganese, Per Cent	Sulphur, Per Cent	Phosphorus, Per Cent
Desired analysis of castings	1.80	0.70	0.08	0.50
Changes in composition	0.20	0.12	+0.02	+0.02
Composition of total metal mixture charged	2.00	0.82	0.06	0.48
Pig iron—pile *A*	2.83	0.96	0.04	0.40
Pig iron—pile *B*	1.34	0.98	0.03	0.38
Pig iron—pile *C*	2.00	0.80	0.04	0.43
Returned foundry scrap (30 per cent of mix used)	1.80	0.70	0.08	0.50
Purchased scrap (20 per cent of mix used)	1.65	0.70	0.08	0.45
Average analysis of scrap (50 per cent of mix used)	1.74	0.70	0.08	0.48
Composition of pig iron mixture (50 per cent of mix used)	2.26	0.94	0.04	0.48

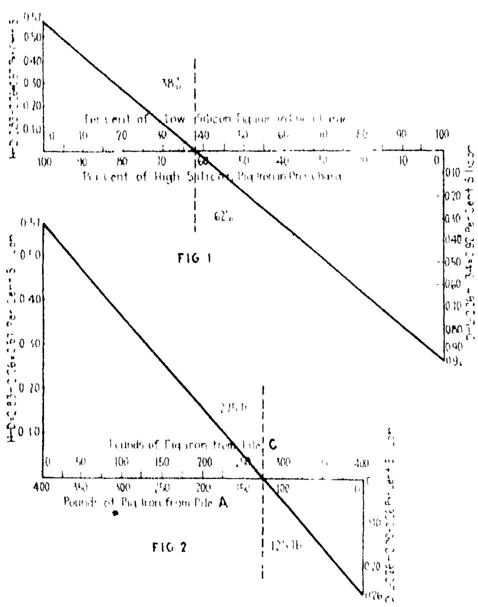
Second, find the difference in the high and desired percentages of silicon in the metal.

Third, plot this difference in any convenient scale, at right angles to one end of the base line.

Fourth, find the difference in the desired and low percentages of silicon in the metal.

Fifth, plot this difference in the same scale as was previously used, at the other end of the base line and in the opposite direction.

Sixth, connect the extremities of the graph by a straight line. The point of intersection will then divide the base line into two parts corresponding to the proportions of high- and low-silicon pig iron in the mixture.



FIGS. 1 AND 2—METHOD OF ESTIMATING CHARGE FOR DESIRED SILICON CONTENT IN CASTINGS

The portion of the total mixture lying adjacent to the *H-D* line represents the amount of metal with a low content of the special element. The portion of the base line lying adjacent to the *D-L* line represents the amount of metal with a high content of the special element.

To illustrate the graphical method by another example: suppose it is desired to mix piles *A* and *C* to obtain 2.26 per cent silicon in the pig iron mixture containing 400 lb. of metal. The solution is given in Fig. 2.

To Obtain Exact Quantities of Two Elements in a Mixture

In the previous problems the amount of pig iron from each of the two piles was found which would give a definite content of one element, silicon, in the final castings. A pig iron mixture may be proportioned to give definitely two elements in the resulting product, providing there are available at least three piles of pig iron with analyses within a limiting range. It is rarely desired to control more than two elements in a metal mixture for cast iron.

In order to determine whether it is possible to obtain the required silicon and manganese contents from three

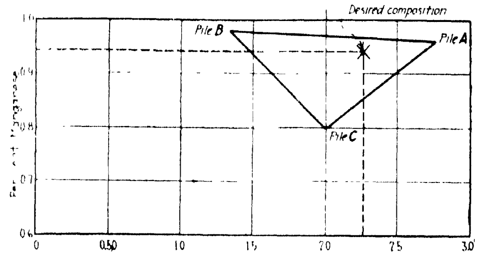


FIG. 3—SCHEME FOR DETERMINING WHETHER AVAILABLE PIG IRON SUPPLIES WILL FURNISH THE DESIRED COMPOSITION

piles of pig iron containing different amounts of these elements, a chart is prepared with two ordinates at right angles on which increasing amounts of silicon and manganese are laid off from the origin. The three points corresponding to the compositions of the three piles of metal are plotted on the chart and connected with straight lines. If the locus of the point representing the required silicon and manganese falls within the triangle, it is possible to mix the three piles of pig iron to obtain the exact silicon and manganese required. All combinations of silicon and manganese represented by points lying outside of the triangle cannot be produced exactly from the three compositions available.

On Fig. 3 the points corresponding to the compositions of the three piles of pig iron given in Table I are plotted. Also, the point corresponding to the desired silicon and manganese in the pig iron mixture is shown. As this point lies within the area of the triangle, it is possible to obtain the desired silicon and manganese in a mixture of the three piles of pig iron. The amount of metal from each of the piles may be determined as follows:

Let M = lb. of metal in total pig iron mixture.
Let X = lb. of metal from pile A.
Let Y = lb. of metal from pile B.
Then $M - X - Y$ = lb. of metal from pile C.

First, balance the equation for silicon

$$2.83X + 1.34Y + 2.00\,(M - X - Y) = 2.26M$$
$$2.83X + 1.34Y + 2.00M - 2.00X - 2.00Y = 2.26M$$
$$0.83X - 0.66Y = 0.26M$$

Second, balance the equation for manganese

$$0.96X + 0.98Y + 0.80\,(M - X - Y) = 0.94M$$
$$0.96X + 0.98Y + 0.80M - 0.80X - 0.80Y = 0.94M$$
$$0.16X + 0.18Y = 0.14M$$

Third, solve for X and Y

$X = 0.55M$ lb. of pig iron from pile A.
$Y = 0.29M$ lb. of pig iron from pile B.
$M - X - Y = 0.16M$ lb. of pig iron from pile C.

Manganese May Be Increased by Ladle Additions

If there is not a sufficient range of composition of pig iron on hand to allow the control of both silicon and manganese in the mixture, or if the manganese is too low in the pig iron available, the manganese content of the metal may be increased by the addition of ferromanganese to each ladle of molten metal. For this purpose, ferromanganese containing 80 per cent manganese is generally used. About one-half of the

manganese added in the ladle is lost by oxidation or in the slag. As the melting point (2,210 deg. F.) of this alloy is close to the melting point of cast iron, the ferromanganese should be crushed, preheated and stirred well into the molten metal.

The task of computing metal mixtures in the foundry may be neglected, unless some simple means is provided for arriving at the correct mixtures. To facilitate the rapid and accurate determination of the charges for cast iron, charts may be prepared from which the relative quantities of the different metals making up the charges may be read directly.

The curves in Fig. 4 have been plotted to obtain directly all possible combinations of any piles of pig iron which will have an average silicon content of 2.10 per cent. Using this figure as the origin, decreasing percentages of silicon are laid off on the base line toward the right. On the left side of the chart are arranged, in columns, the scrap and pig for every possible mixture. Each lot of high-silicon pig is represented by a curve. In order to find the correct mixture of any two cars of pig iron which will produce the desired composition in the castings, a line is drawn

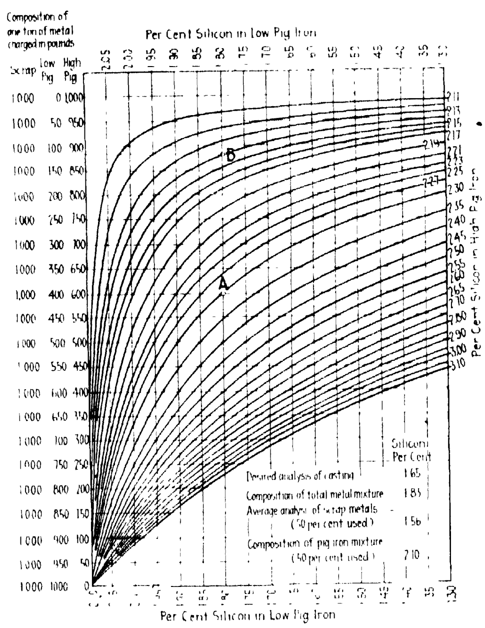

FIG. 4—CURVES FOR ESTIMATING MIXTURES FOR 2.10 PER CENT SILICON CASTINGS

vertically from a point on the base line which corresponds to the silicon in the low-silicon pig to the intersection of the curve which represents the per cent silicon in the high-silicon pig iron; and from this point of intersection a horizontal line is drawn to the left which will indicate the proper weights of scrap, low-pig and high-pig for each charge.

If it is desired to use three or more lots of pig iron to a charge, the mix for any two lots must be found first and then any proportion of the different mixes may be added up to give the full charge.

As an example: Suppose the scrap metals average 1.56 per cent in silicon and there are two cars of pig iron on hand containing 1.80 per cent and 2.30 per cent silicon. Point *A* in Fig. 4 is the intersection of the two curves and the horizontal line through this point indicates that a full charge will consist of 1,000 lb. of scrap, 400 lb. of low-silicon (1.80 per cent) pig iron and 600 lb. of high-silicon (2.30 per cent) pig iron. If in addition to the two cars of pig iron there is in the foundry yard a small pile of 440 lb. of pig iron containing 2.14 per cent in silicon, then the correct charge may be found as follows: It is shown on the chart (point *B*) that 120 lb. of low-silicon (1.80 per cent) pig iron must be mixed with 880 lb. of high-silicon (2.14 per cent) pig iron or that one-half of this mixture will use up all of the 2.14 per cent silicon pig iron. Therefore one-half of this mixture must be added to one-half of the mixture from the two cars in order to give the total charge, which will consist of 1,000 lb. of scrap, 260 lb. of 1.80 per cent silicon pig iron from car, 300 lb. of 2.30 per cent silicon pig iron from car and 440 lb. of pig iron from yard.

In the preparation of similar charts it is first necessary to determine the silicon content of the pig mixture, the total charge and the proportion of scrap to be used. When these values are established, the curve for each high-silicon pig iron may be plotted.

m = lb. of pig iron in one charge.
x = lb. of low-silicon pig in one charge.
$(m - x)$ = lb. of high-silicon pig in one charge.
q = per cent silicon in low-silicon pig iron.
r = per cent silicon in high-silicon pig iron.
s = per cent silicon in pig iron mixtures.

$$(q \times x) + [r \times (m - x)] = m \times s$$

$$\text{therefore } x = \frac{(m \times s) - (m \times r)}{q - r}$$

By fixing m and s and keeping r constant for any curve, x may be found for different values of q. When the points are plotted on co-ordinate paper a set of curves similar to those in Fig. 4 will be produced.

When the melting practice has been established and a chart has been prepared, all possible mixtures may be taken directly from the chart. Slight variations in the analysis of scrap will produce only small changes in the composition of the resulting metal. A separate chart must be used for each different composition of metal required. As most foundries have not more than three standard compositions of castings and the average composition of scrap metals need not vary excessively, a few charts may be prepared and used to great advantage.

Engineering Societies Library

It is perhaps not as widely known as it should be that the United Engineering Societies maintain a very large and efficient library in the Engineering Societies Building, 29 West 39th St., New York City. This library is open to all members of these societies, and to other engineers by courtesy. Members are permitted to withdraw certain books from the shelves, which are mainly duplicates. Most of the readers in the library, however, are interested in matters contained in recent technical periodicals, or are making an extensive search to exhaust a certain subject.

At present the library contains about 117,000 volumes, 32,000 pamphlets and 3,000 or 4,000 miscellaneous pieces of literature. While these are not entirely indexed, in the last 3 years about 150,000 cards have been added to the catalog. There is now available 50,000 subjects presented to prospective readers in a systematic and logical relation. These subjects are handled in two different ways: The searcher who wishes to exhaust his field will find all entries arranged from the large group down to the most minute in one place. The casual reader who wants a minute subject has an alphabetic subject index available.

Schroder Roofing Patent Invalid

Crushed Slate Used for This Purpose More Than Two Years Before Application

The United States Circuit Court of Appeals has held the Schroder patent No. 1,007,146 invalid because anticipated. The decision was made in a suit brought by the Staso Laminated Slate Co., owner of the patent, against the Stowell Manufacturing Co. 280 Fed. 107.

Crushed Slate Claimed Superior to Ground Product

The patent is for a prepared roofing, which consists of a body portion having a coating of adhesive waterproofing material, such as asphalt and an outer protective coating of crushed slate. The alleged novelty in this patent is twofold: Material and method of application of crushed slate, applied by rolling in contact with an adhesive coating of asphalt. Ground slate had been used in the John's patent of 1872, No. 125,574. It was claimed that crushed slate is superior to other kinds of slate material, because slate laminates when crushed and the laminæ when rolled and pressed together match and overlap one another, so as completely to cover the asphalt coating and give a smooth surface and uniform color which cannot be obtained with a gravel, sand or other crystalline covering. This result cannot be secured, so it was claimed, by the use of ground or powdered slate, because it has no laminæ to match and overlap one another.

The defendant contended that the patent was invalid because Edward J. Schroder was not the original and first inventor, claiming that A. C. Hall was the inventor of substantially the construction described and claimed in the patent which had been in public use or on sale in the United States more than 2 years before the aplication for the Schroder patent.

Similar Product Marketed in 1906

Defendant cited the roofing called "Slateoid" manufactured by the Trinidad Asphalt Manufacturing Co. of St. Louis. This word was registered as a trademark by the company in 1906. It appears that A. C. Hall was employed by the Staso Mills, or Staso Milling Co., of Boston, Mass., as its superintendent from 1906 to 1913. That company was making slate dust in 1906 which was used in making paint and linoleum. This dust had to be screened, and it occurred to Mr. Hall that the larger screenings would make a good material for roofing. He sent samples to various roofing manufacturers, among whom was the Trinidad Asphalt Manufacturing Co. It approved the material and ordered two carloads. The factory of the Staso company was therefore equipped for crushing slate ordered by the Trinidad company. Eight carloads was shipped to that company. The Staso company called the material "torpedo slate." The Trinidad company made and sent sample of Slateoid to the Staso company, and these samples were, Hall testified, like the material manufactured by the Staso Laminated Slate Co. and submitted to him at the trial.

The Trinidad company showed that it manufactured and sold 9,394 squares of "Slateoid," enough to cover 1,657 average size houses, before Sept. 9, 1908, which was 2 years before the application for the Schroder patent. On March 21, 1907, Frank W. Torpening, of the Trinidad company, filed an application for a patent on the Slateoid roofing made by his company. Claim 2 specifies: "A roofing sheet comprising a pliable body, a non-hardening bond applied to said body, and a layer of crushed slate imbedded in said compound, substantially as set forth."

Earlier Application for Patent on Identical Material Rejected

This application was rejected by the Patent Office on the ground that substitution of crushed slate for other material did not constitute invention. This application was filed 3½ years before the Schroder application, using the identical material, crushed slate, and applied in identically the same way.

Complainant disposed of the Trinidad roofing by saying that it was only an experiment and a complete failure, that its manufacture was abandoned, and therefore it should not be held as an anticipation. The court, however, held that such conclusions were not justified by the evidence. It found that substantially the same roofing was successfully manufactured out of the same material, by the same method as described in the Schroder patent more than 2 years before his application. Hence the patent in suit was anticipated and invalid.

The enterprise of the patentee and his assignee was commercially successful. The roofing has been applied in large quantities, both in the form of sheets or roll roofing or shingles. Commercial success is often indicative of invention, but it is not always so, for it may be due to other causes, said the court.

Novel Claim for Damages

Concern Asks Refund for Goods Delivered to It but Not Exportable Because of Embargo

A novel claim for damages is involved in an action brought by the Bencoe Exporting & Importing Co. against the Erie City Iron Works and the John O'Brien Boiler Works Co. The facts appear to be that plaintiff took an order from a Japanese corporation for 300 tons of boiler plates in July, 1917, to be shipped to Yokohama. In order to get the plates plaintiff made a contract with the Aetna Co. to purchase "300 tons of boiler plates for export to Japan," the price being so much per pound "f.o.b. mill Pittsburgh base . . . shipping instructions to be given later." Thereafter the Aetna Co., for the purpose of in part fulfilling its contract, in turn further contracted with the defendant, Erie Works, for 200 tons of the boiler plates. It further appears that at least a part of this order was to be filled through the O'Brien Boiler Works, which in turn had a contract for plates from the Illinois Steel Co. In August, 1917, the President of the United States had ordered that no boiler plates should be delivered for export after certain dates.

Plaintiff charges that the defendant conspired to obtain 200 tons of plates from the Illinois Steel Co. under the latter's contract with the O'Brien Works, by concealing the fact that they were intended to be shipped in fulfillment of an export contract and were not to be

used by the O'Brien Works itself in domestically manufacturing boilers. Having obtained the plates, the defendants shipped the same to the order of the Erie Works in the form required by irrevocable letter of credit previously obtained from the plaintiff. Having been thus paid for, the plates were delivered to plaintiff, but owing to the governmental restrictions they could not be exported nor used to fulfill plaintiff's contract with the Japanese corporation. Plaintiff filed its complaint in two counts, asking $45,000 as damages under the above statement and $50,000 for loss of the sales from the following facts as set out:

The substance of the second cause of action is that on and after Oct. 2, 1917, the plaintiff sold for export certain articles which under the regulations then existing were exportable, providing a license therefor were obtained pursuant to the orders of the President of the United States. The complaint continues that the acts of defendants set forth in the first cause of action, "in procuring by fraud the manufacture and shipment of the boiler plates, were discovered by government agents and reported to the Department of Commerce and by the latter attributed to plaintiff," whereby said department refused all licenses to plaintiff and it lost the sales aforesaid. Its damages were put at $50,000.

The U. S. District Court gave judgment on demurrer and dismissed both causes of action. On appeal the U. S. Court of Appeals reversed the judgment as to the first cause of action and affirmed it as to the second. As to the second, it says a complaint, alleging that illegal acts of defendants were erroneously or stupidly imputed to plaintiff by governmental agents, in consequence of which plaintiff was refused a license to export certain merchandise, the sale of which it had contracted, does not state a cause of action against defendants for damages in the absence of any allegation that defendants communicated with the government agents or in any way caused or contributed to their error.

Exportable Attribute Involves More Than Physical Properties

The court, however, does hold that the first cause of action is a good one, though it is novel and most interesting. The lower court held that the reference in the contract to export of the goods was no more than a "description." Plaintiff contended that what he bought were plates "for export to Japan" and the knowledge that this was plaintiff's bargain was passed on from the Aetna Co. to the Erie Works and to O'Brien. The lower court held the contract required no more than the delivery to plaintiff in the United States of plates physically complying with requirements as to quality, size, etc. Hence since plaintiff had got plates physically acceptable, he had no cause of complaint, for no fraud had been worked on him by anyone, and he got "exactly what he had contracted for." The fact that plaintiff's goods, exactly as contracted for, had been procured for him by frauds or falsehoods worked on the Illinois Steel Co. and the United States was quite immaterial. In terms of the rule of law the lower court held there was no concurrence of fraud and damage to the damage of plaintiff.

But the Court of Appeals could not read the complaint as making the exportable quality or attribute of these boiler plates no more than descriptive. Instead it found that it was part of the original bargain between plaintiff and the Aetna Co., and part of the fractional bargain between Aetna Co. and Erie Works, and something communicated to and known by O'Brien, that plaintiff was not getting what he was entitled to and was not obtaining fulfillment of his contract, unless the plates tendered him had not only the stipulated physical qualities but possessed also the political or legal and additional quality or attribute of exportability.

"Whether there ever was such a singular and burdensome contract we do not know; but we hold it clear that an agreement of that kind is possible, and would be legal, and further that it is such a contract that plaintiff has with reasonable clarity alleged. Therefore he is entitled to an opportunity of proving it before a jury," says the court. (280 Federal Rep. 690.)

Etching Reagent for Steels Containing Chromium and Vanadium

Considerable attention has been paid at the Bureau of Standards to the problem of finding an etching reagent by which chromium carbide could be distinguished from vanadium carbide in a positive and satisfactory manner. Only one out of about twenty reagents tried seemed likely to be of much use in this connection. This is a hot solution of potassium permanganate and sodium hydroxide, etching in which for 1 minute darkens chromium carbide to a strong brown-red or brown color, or rather, the carbon is eaten out, giving the walls of the cavity thus formed a dark brown-red color, while vanadium carbide remains uncolored and apparently unattacked.

Another but less positive means of distinction is that obtained by electrolytic etching with a weak current in a dilute aqueous solution of ammonia or sodium hydroxide. The chromium carbide is eaten out, leaving a dark brown-red or brown cavity, while the vanadium carbide is eaten out apparently at a slower rate, leaving cavities which appear light and not at all darkened.

Second Sorby Lecture

Dr. Cecil H. Desch, professor and dean of the faculty of metallurgy in the University of Sheffield, delivered the "Second Sorby Lecture" on "The Services of Henry Clifton Sorby to Metallurgy." The Sorby lectureship has been instituted by various Sheffield engineering associations to commemorate the work of Dr. Sorby, who rendered such signal service to science in general, and to the special branch of microscopy in particular. It is expected to have a lecture delivered each year by an eminent scientific authority on some subject which arises out of Dr. Sorby's work, and thus promote an increased interest in scientific research. E. J. Thackery, at Sheffield University, is acting as secretary of the fund.

Helium From Canadian Natural Gas

From the physical laboratory at the University of Toronto comes the report that a process for liquefying helium gas has been perfected by Prof. J. C. McLennan. Several years ago Professor McLennan discovered that helium existed in large quantities in natural gas in Canada, and since then various experiments have been made by him to discover such a process.

In 1919 a semi-commercial plant was constructed in Calgary for the extraction of helium from natural gas, the natural gas being piped to Calgary from the Bow Island Field.

Synthetic Ammonia By the Claude Process*

An Outline of Georges Claude's Claims as to the Advantages in the Installation and Operation of Plants Using the Superpressure Method as Compared With the Haber-Bosch Process for Fixation of Atmospheric Nitrogen

TODAY, the production of synthetic ammonia on a commercial scale is well established. As is already well known, the principal process is that of Haber, which is based on the fact that nitrogen and hydrogen are caused to react under the simultaneous influence of pressure (200 atmospheres), heat (about 600 deg. C.) and a catalyst (essentially iron). The process developed by Georges Claude is based on much the same principle, but uses far greater pressure. The difficulties encountered in the use of this superpressure are three in number: Safety, operating difficulties, and cost.

Safety—Obviously, the use of such high pressure calls for very careful selection of materials. There are on the market, however, steel and alloys satisfactory for making tubes which will resist 1,000 atmospheres pressure at 600 deg. C., and catalyzing tubes which will resist more than 5,000 atmospheres. Thus the safety factor is one of construction rather than of construction material.

Operating Difficulties—The main requisite is that the joints be tight. It is known, however, that this depends more on the size of the joint than on the pressure it has to withstand. Considering the relatively small sizes used in the superpressure apparatus to handle the same amount of gas, a tight joint for 1,000 atmospheres, other conditons being equal, is smaller than that needed for 100 atmospheres in some other processes.

Cost—The production of superpressure is not particularly difficult. It will be noted that an ordinary compressor of five cylinders having relative cylinder volumes of 300, 100, 30, 10, and 3 (See Fig. 1) giving 300 atmospheres pressure, will become a supercompressor by the addition of a sixth cylinder having a relative volume of 1, and will be capable of giving 900 atmospheres pressure. Accordingly the additional cost of producing the superpressure is proportionally small.

*Abstracted and translated by J. S. Negru and S. D. Kirkpatrick from papers appearing in the *Mémoires et Comptes Rendus de la Société des Ingénieurs Civils de France*, Bulletin of April-June, 1922

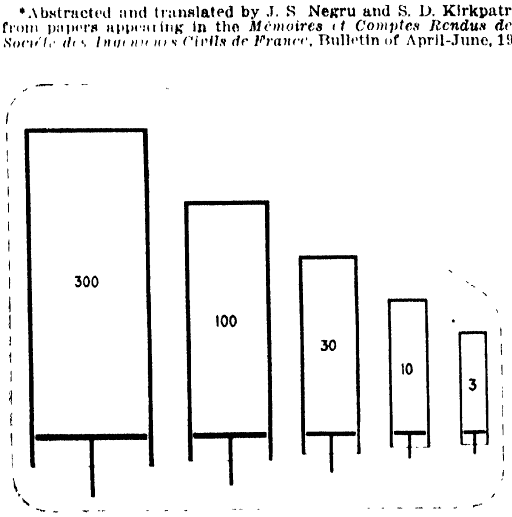

FIG 1—VOLUME RELATION IN A SUPERCOMPRESSOR
The addition of a sixth cylinder of relative volume 1 added to the five other cylinders changes the 300-atm. compressor into a 900-atm. supercompressor.

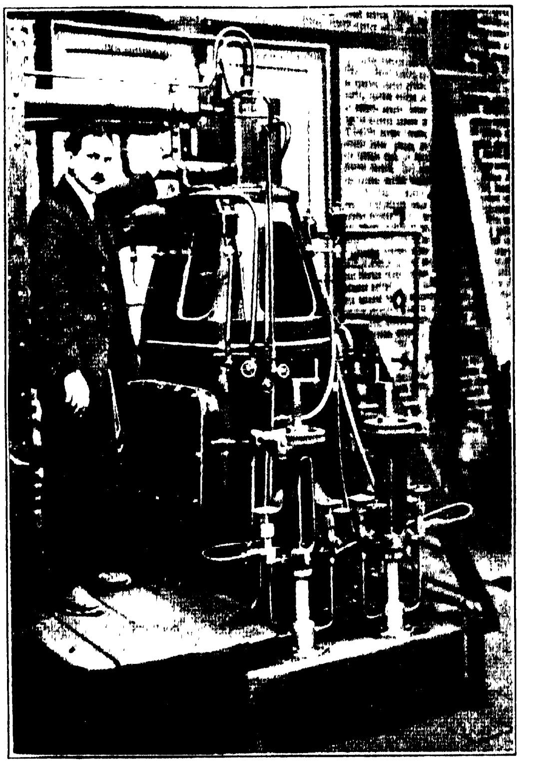

FIG 2—A SUPERCOMPRESSOR AT THE GRANDE PAROISSE PLANT
This compresses 700 cu.m. of gas per hour to 900 atm

Fig. 2 shows the size of a two-stage supercompressor capable of supplying pressure at 900 atmospheres to the volume of gas required for a daily production of 5 tons of ammonia or 25 tons of ammonium sulphate. The operation of the supercompressor is comparatively simple and is said to require no special attention. Fig. 3 shows the assembly of the compressor and the supercompressor. It is an eight-stage apparatus of 300 hp., compressing 700 cu.m. of gas per hour to 900 atmospheres. This particular installation is at the Grande Paroisse plant.

SUMMARY OF ADVANTAGES CLAIMED

The advantages of the superpressure process have been summarized by Mr. Claude as follows:

While the efficiency of the Haber process in terms of ammonia production is 6 per cent, that of the Claude process can reach 25 per cent. This was proved by actual experimentation carried out in the latter part

of 1917. The curves of Fig. 4 show the relation between the pressure and efficiency in ammonia production at temperatures between 500 and 700 deg. C. Curve I shows the theoretical relation, curve II the relation obtained by extrapolation, based on the results obtained by the Haber process, and curve III the relation as plotted from Claude's experiments.

The increased efficiency is not obtained as a result of increased expense, since the work of obtaining superpressure increases only proportionately with the logarithm of the pressure, and if it costs, say, 2.3 to obtain 200 atmospheres pressure, it will cost only 3.0 to obtain 1,000 atmospheres pressure.

It will be recalled that in the Haber processes the gases are forced to pass through the catalyzer tubes many times, and each time the ammonia produced is withdrawn. By the use of the superpressure process, the reaction is highly intensified and larger amounts of ammonia are formed in smaller volumes. Thus for capacities of 100 cu.m. of gas per hour per liter of catalyzer space Claude produces over 5 kg. of ammonia per kilogram of catalyst per hour instead of 0.5 kg. by the Haber process.

The essential characteristic of the superpressure process, of course, is that the installation is in miniature, and this brings with it a great advantage as to

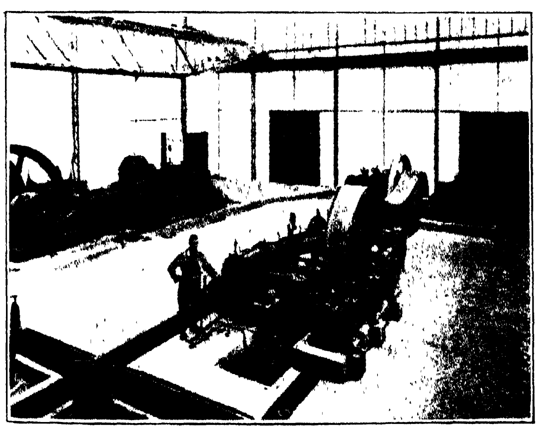

FIG. 3—A 300-HP. SUPERCOMPRESSOR

This machine is for a 5-ton NH_3 plant at Grande Paroisse, compressing 700 cu.m. of gas per hour to 900 atm

cost of installation and operation. Thus Fig. 5 shows the structure for the five catalyzer tubes of a 5-ton per day ammonia plant. Tubing not larger in diameter than a man's thumb is sufficient for a flow of 700 cu.m. of gas per hour. Fig. 6 shows the assembly of the condensation, extracting and storage equipment required by a plant of 2 tons per day of ammonia. These figures show clearly the small size of plants which are reported to be working with entire satisfaction.

With 1,000 atmospheres pressure, at which an efficiency in ammonia production of 25 per cent is easily obtainable, the vapor pressure of the ammonia produced is 250 atmospheres. As the maximum vapor pressure of ammonia at ordinary temperature is only about 7 atmospheres, it is only necessary to pass the reaction gases through a worm pipe condenser immersed in water to liquefy theoretically $(250 - 7) \div 250 = 97.2$ per cent of the ammonia produced. On the other hand, in the Haber process, a 6 per cent efficiency for ammonia production at 200 atmospheres yields a product under only 12 atmospheres of pressure as compared with 250

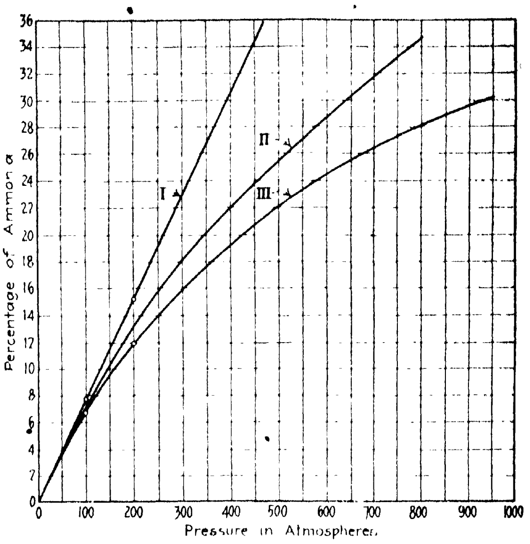

FIG. 4—RELATION BETWEEN PRESSURE AND EFFICIENCY AT THE SAME TEMPERATURES

Curve I—Theoretical relations. Curve II—Extrapolation with Haber's results. Curve III—Claude's experimental results.

in the Claude process, and less than 50 per cent of the formed gas could be condensed with a worm pipe condenser immersed in water. In the Haber process, therefore, it is necessary to remove the ammonia by injecting water under 200 atmospheres pressure, an operation not needed in the Claude process. Furthermore, in the Haber process the water solution of ammonia must be distilled in order to recover the ammonia. Therefore the expense of installation, labor and heat adds to the cost of the final product. In the Claude process, on the other hand, liquid ammonia is obtained as the first product.

Another fundamental difference in the two processes is that in the Haber process the gases must be passed through the catalyzer tubes many times, thus requiring expensive pumps and circulating equipment. In the Claude process it is sufficient to pass the gases through three or four consecutive catalyzer tubes which are separated simply by water coolers. The Claude process therefore does not require the costly heat-exchanging equipment required by the Haber process.

Another very important advantage is allied with the purity of the gases. In the Haber process very high

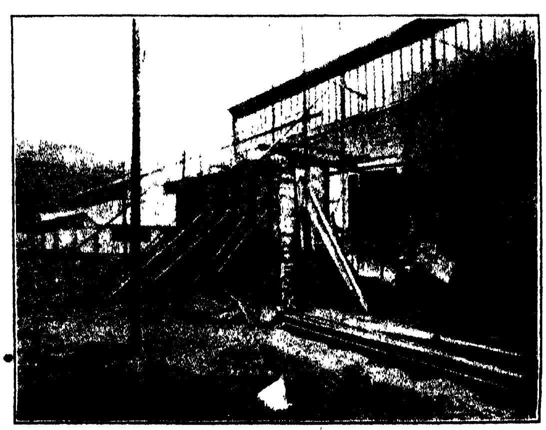

FIG. 5—STRUCTURE CONTAINING FIVE CATALYZER TUBES FOR A 5-TON AMMONIA PLANT

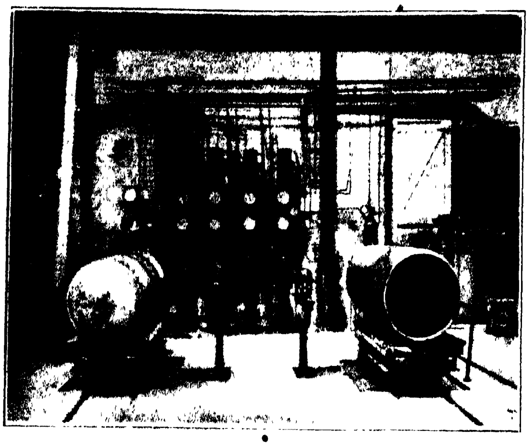

FIG. 6—ASSEMBLY OF THE CONDENSATION, EXTRACTION AND STORAGE EQUIPMENTS FOR A 2-TON AMMONIA PLANT

purification is indispensable. Hence costly absorption towers, batteries of pumps, injectors for circulating under 200 atmospheres pressure the purifying solutions of cuprous formate, caustic soda, etc. In the Claude process these installations are not needed. Here the gases containing as high as 4 per cent of carbon monoxide can be used with entire safety. It is sufficient to pass the supercompressed gases through a simple tube containing reduced iron heated at 300 and 400 deg., whereupon the oxygen burns to water and the carbon monoxide into water and methane, the water being drained out periodically and the methane being without harmful properties as far as the catalyst is concerned. By this simple arrangement the catalyst can last 200 hours.

One of the principal difficulties which was encountered in the superpressure process was to absorb the large amount of heat generated by the reaction. In the Haber process the quantity of heat generated is relatively small, since only 11 per cent of the gases react. In the Claude process, on the other hand, 40 per cent of the gases react under 1,000 atmospheres pressure in a very small volume. As much as 60,000 calories per hour are generated in a tube only 10 cm. in diameter and 2 m. long. This enormous quantity of heat has to be eliminated, and the elimination must take place under the most favorable temperatures so as not to freeze the tubes by too low a temperature and not to destroy the chemical equilibrium by too high a temperature, since this would also destroy the tubes. The problem to be solved was to maintain the catalyst at the most favorable temperature—namely, about 550 deg. C.—and it is necessary that the gases reach the catalyst at this temperature. In the Haber process this is realized by heating the incoming gases with exhaust gases. In the Claude process the special construction of the catalyzer tubes solves the problem of cooling the catalyst, and at the same time enables the heating of the incoming gases with the heat from the catalyst. The catalyzer tubes are constructed as is shown[1] in Fig. 7. The cold incoming gases at A are heated progressively by absorbing the heat of the catalyst in the tube E. This tube is so proportioned that by the time the reaction gases reach the catalyst at the top they are already heated to the required temperature.

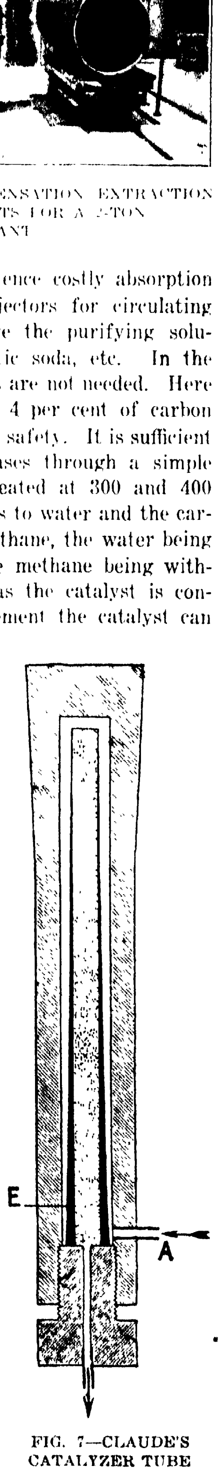

FIG. 7—CLAUDE'S CATALYZER TUBE

By this arrangement both the catalyst and the gases reaching it are at the most favorable temperature without the need of any additional heat exchanges. Furthermore, excessively high temperatures are not reached, so the life of the tube is not endangered.

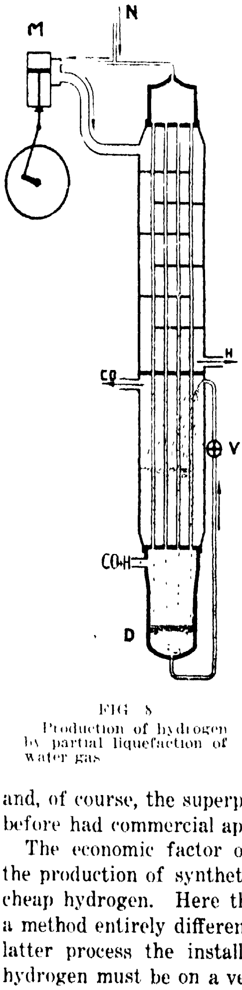

FIG. 8
Production of hydrogen by partial liquefaction of water gas

This arrangement also has the great advantage of permitting the easy handling of the tube and the substitution of tubes with new catalyzing material, much the same way in which shells are loaded into heavy guns.

It is significant that in the Haber patent reference is made to the use of pressures of 200 atmospheres and more, so that it is now rumored that the Badische Aniline & Soda Fabrik would like to claim the application of the superpressures used by Claude. However, all of the literature of Haber and the Badische company states clearly that they had in view only the highest pressures which were then used industrially, and, of course, the superpressures of Claude have never before had commercial application.

The economic factor of predominant importance in the production of synthetic ammonia is the problem of cheap hydrogen. Here the superpressure process uses a method entirely different from that of Haber. In the latter process the installations for the production of hydrogen must be on a very large scale. In the Claude process the installation for this work is on a very much reduced scale and can easily be installed at places where hydrogen is already being produced as a useless byproduct. Thus utilization could be made of the exceptionally cheap source of hydrogen at coke works to be found in all of the leading industrial centers.

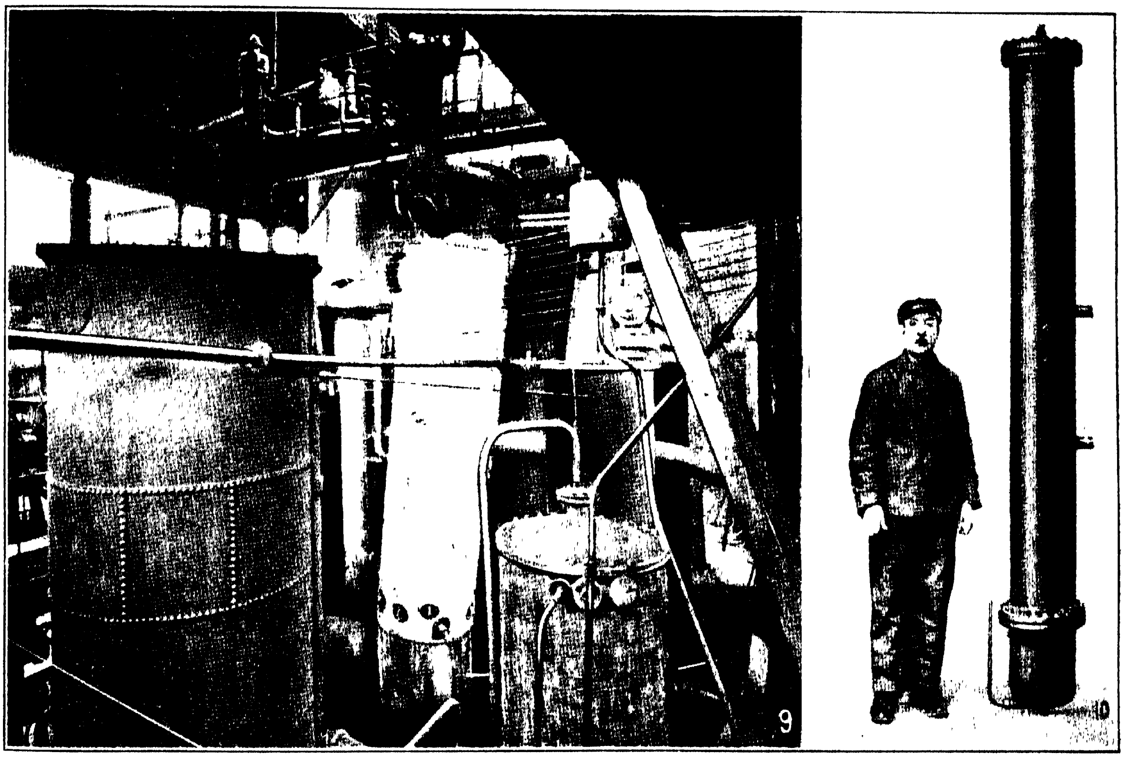
[1]It may be of interest to mention here the typical example of the relation between the chemical and metallurgical industries. The synthesis of ammonia would have been retarded many years if there were no metallurgical products which could resist simultaneously the wide range of temperatures and pressures needed in this important chemical industry. The success of Claude's process is largely to be attributed to the fact that he had unusually good tubes. These were made of an alloy known as B.T.G. of Imphy, which resists perfectly not only the temperatures and pressures used but also the action of the gases. Léon Guillet made a thorough study of this alloy, the chemical analysis of which is C, 0.44; Ni, 60.40; Cr, 8.70; W, 2.52; Mn, 1.80; Fe, 24.73.

It is true, of course, that this crude hydrogen is in realty a complex mixture of hydrogen with nitrogen, carbon monoxide, methane, ethane, butane, ethylene, carbon dioxide, hydrogen sulphide, etc., but Claude has succeeded in purifying it economically. This purification is based on the principle of gas liquefaction, hydrogen being the most difficult to liquefy.

This, of course, is in a field in which Claude's name is already well known. As early as 1903 he had studied the mixture of equal volumes of CO and H (water gas). The gases compressed and purified were cooled and forced to enter a multi-tubular cylinder. (See Fig. 8.) The lower part of the cylinder is immersed in a bath of boiling carbon monoxide, yeilding a temperature of —190 deg. C. at atmospheric pressure. At this temperature, the greater part of the CO in the mixture is liquefied, collected at *D*, and fed through the valve *V* to the exterior bath. The remaining hydrogen and the unconaensed carbon monoxide continue to ascend the tower, where they encounter even a lower temperature at which all of the carbon monoxide is liquefied. This last temperature is produced as follows: Only the pure compressed hydrogen enters the cylinder *M*, where it expands and becomes much colder. This is then returned to the multi-tubular cylinder, thus producing the needed low temperature to liquefy the remainder of the CO in the ascending gases.

The principal difficulty encountered was that at a temperature of —210 deg. C., needed to condense all of the carbon monoxide, there was no known lubricant which could be used to enable smooth working of the motor. This has been solved, however, by a very simple expedient. As the ultimate aim is to have the mixture of pure nitrogen and hydrogen, the introduction of nitrogen before the hydrogen entered the cylinder *M* is not at all harmful. This nitrogen is immediately liquefied after each expansion and the liquid nitrogen acts as a lubricant, since it freezes only at —210 deg. C. This very simple solution of the problem has been a very helpful step toward the practical success of the superpressure process. And so, instead of having an installation of the size shown in Fig. 9, merely two tubes of the size shown in Fig. 10 will be sufficient for the production of 24,000 cu.m. of pure hydrogen per day.

The problem of purification of hydrogen from coke-oven gas is solved in practically the same manner as has been described for water gas, and an apparatus installed at the coke plant of the Béthune Coal Co. now gives 800 cu.m. of pure hydrogen per hour. A plant is now being erected at this same works which will produce 3 tons of ammonia per day, using this source of hydrogen.



FIGS 9 AND 10—COMPARATIVE SIZE OF HABER AND CLAUDE INSTALLATIONS FOR HYDROGEN PURIFICATION
Two tubes of Fig 10 are sufficient to produce the same amount of pure hydrogen as the Haber installation shown in Fig. 9 (24,000 cu.m. per day)

This, it would seem, is the beginning of the practical realization of Claude's plans to have a number of small plants located near the sources of cheap hydrogen and convenient for the cheap manufacture of the finished product (fertilizer).

It may be mentioned that as a byproduct of the operation for the extraction of pure hydrogen from coke-oven gas it will be possible cheaply and completely to extract both the benzol and ethylene.

Although the present variations in the foreign exchanges and labor costs render all figures quite empirical, it may be stated that according to Claude's claims the cost of installation per ton of synthetic ammonia by the superpressure process is less than half the cost when using t' Haber process. The relative simplicity of operation of Claude's process and the fact that it can be installed in small units are also to be taken into consideration.

Influence of Cooling Rate on Properties of Carbon Steel

AT THE recent meeting of the American Institute of Mining and Metallurgical Engineers, Francis B. Foley and Joseph Winlock, of the Bureau of Mines, presented the results of an extended investigation, directed by the late Henry M. Howe, on the "Influence of Temperature, Time and Rate of Cooling on the Physical Properties of Carbon Steel." They had ⅝-in. bars of well-made acid open-hearth steel, with 0.34, 0.52 and 0.75 per cent carbon. These were heated at a uniform rate in groups in a special electric tube furnace and cooled at various rates, ranging from a retarded furnace cooling (0.01 deg. C. per second through Ar) to a 4-second quench in water, followed by air cooling (20 deg. C. per second).

In the so-called "basal" experiments the temperature of annealing (T_{max}) was 10 deg. C. above Ac_3. This temperature was retained 10 minutes, it having been found that this was sufficient to show no ferrite in a quenched and tempered specimen. Longer times and higher temperatures were also investigated.

Optimum values of the physical properties seem to occur with a cooling rate of about 2 deg. C. per second at Ar (resulting from a 2-second quench in water followed by air cooling, $T_{max} = Ac_3 + 10$). Faster cooling rates lower the ductility and impact resistance; slower cooling rates lower all properties measured. A great mass of basal experiments have been summarized in the following equations, in which c is the percentage of carbon, and R is the rate of cooling in deg. C. per second between Ac_3 and 585 deg. C.:

Proportional Limit

$$= 21{,}750\,(1 + \tfrac{1}{2}c) + [(115{,}225c - 101{,}100c^2 - 12{,}250)\sqrt{R}]$$

Yield Point

$$= 25{,}000\,(1 + c) + [(89{,}680c - 86{,}185c^2 - 8{,}080)\sqrt{R}]$$

Tensile Strength

$$= 50{,}000\,(1 + c) + [(7{,}023 - 11{,}450c + 50{,}780c^2)\sqrt{R}]$$

$$\text{Stress of Rupture} = 118{,}000 + 33{,}200\sqrt{R}$$

$$\text{Per Cent Extension in 2 in.} = 52.1 - 61.4c + 22.1c^2$$

$$\text{Per Cent Contraction of Area} = (79 - 61c)\,R^{.05}$$

$$\text{Charpy Impact} = (51.25 - 111.5c + 64.27c^2)\,R^{.29}$$

$$\text{Brinell Hardness} = (97 + 80c) + [100c\sqrt{R}]$$

It is usually thought that more rapid coolings result in greater hardness at the expense of ductility. As a matter of fact *all* measured physical properties[1] get better with increasing speed of cooling up to the mild quench from $Ac_3 + 10$ deg. C. represented by 2 seconds in water and balance in air. Another unusual fact is found when results of these basal experiments are compared with those having higher and longer periods of heating. It is found that hardness (tensile strength, elastic limit and Brinell number) increases when the 0.52 and 0.75 C steels are quenched from higher temperatures (increasing T_{max}), but *all* properties deteriorate with longer time at T_{max}. Time and temperature have hitherto been supposed to act in the same direction, and they do so in the 0.34 C steel—high T_{max} and long time both damaging the metal. Ductility (elongation, contraction and impact) is impaired by both time and temperature in all carbons, but, as just noted, hardness shows apparent anomalies. These may be studied by examining the relationship between diffusion and grain growth, or coalescence.

It is apparent that the actions going on above Ac_3 are largely diffusion of impurities (including carbon) into austenite, an effect which is practically complete within 30 minutes. As the temperature rises, a second effect appears—namely, the growth of austenite grain. Furthermore, the time spent at or just below the Ar range is largely occupied by the coagulation of the cementite and pearlite formed by the break-up of solid solution.

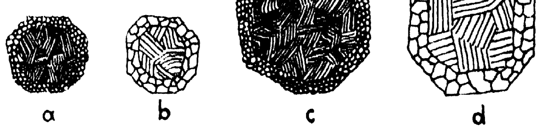
Now, the ferrite shells in a slowly cooled steel inherit the position of the austenitic grain boundaries—if the austenite was overheated for some time the apparent grain size of the cooled steel reflects that fact. However, the cooling of that austenite may have been at such a rate that the minute ferrite and cementite particles thrown out of solid solution (both in ferrite shells and pearlite cores) are extremely fine grained. Then the coarse grain marked by open ferrite shells would be illusory.

The authors illustrate this by the diagram, Fig. 1.

We may therefore have a fine-grained ferrite-carbide structure in a small network *a*, produced by a fairly rapid cooling of a fine-grained austenite; a coarse-grained ferrite-carbide structure in a small network *b*, which results from a very slow cooling of a fine-grained austenite; a fine-grained ferrite-carbide structure in a large network *c*, which results from a fairly rapid cooling of a large-grained austenite; a coarse-grained ferrite-carbide structure with a large network *d*, which results from a very slow cooling of a large-grained austenite.

The ferrite network of annealed hypo-eutectoid steels must be considered a segregate. If this segregate is made up of very fine crystals it is less harmful than one made up of large crystals. Likewise, the grains of pearlite may consist of coarse or fine carbide and ferrite crystals. It is desirable to produce a structure like *a*; but *c* is far better than *b*.

High temperature anneals give coarse-grained, homogeneous austenite, which upon cooling at mild rates gives a structure like Fig. 1 (*d*). As ferrite is the predominant constitutent in the 0.34 C steel, this treatment will do the most damage by producing what is apparently a very coarse grain, and a general deterioration of qualities ensues. On the other hand, uniform austenite will reasonably be responsible for more uniform and fine crystalline pearlite grains of high quality, so that in the higher carbon steels, where the pearlite is the major constituent, hardening and strengthening of the pearlite grain will occur simultaneously with a lower ductility of the pearlite shells.



a b c d

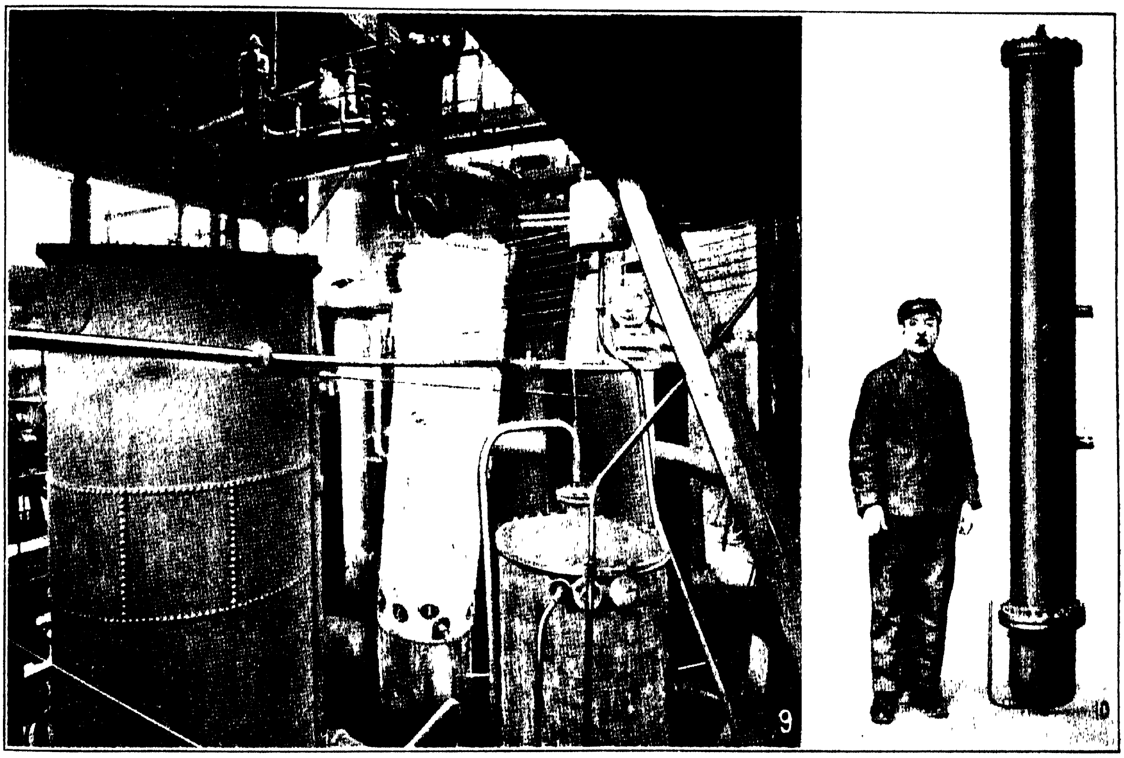
FIG. 1—NETWORK AND GRAIN-SIZE OF FERRITE AND RELATIVE COARSENESS OF PEARLITE LAMELLA

The deduction may be made from all these experiments that ductility and toughness in hypo-eutectoid steel are products of free ferrite, fine crystal structure in both the pearlite and the ferrite binder, and homogeneity in chemical composition.

[1] Except contraction in area, which remains stationary.

It is true, of course, that this crude hydrogen is in realty a complex mixture of hydrogen with nitrogen, carbon monoxide, methane, ethane, butane, ethylene, carbon dioxide, hydrogen sulphide, etc., but Claude has succeeded in purifying it economically. This purification is based on the principle of gas liquefaction, hydrogen being the most difficult to liquefy.

This, of course, is in a field in which Claude's name is already well known. As early as 1903 he had studied the mixture of equal volumes of CO and H (water gas). The gases compressed and purified were cooled and forced to enter a multi-tubular cylinder. (See Fig. 8.) The lower part of the cylinder is immersed in a bath of boiling carbon monoxide, yeilding a temperature of —190 deg. C. at atmospheric pressure. At this temperature, the greater part of the CO in the mixture is liquefied, collected at *D*, and fed through the valve *V* to the exterior bath. The remaining hydrogen and the unconndensed carbon monoxide continue to ascend the tower, where they encounter even a lower temperature at which all of the carbon monoxide is liquefied. This last temperature is produced as follows: Only the pure compressed hydrogen enters the cylinder *M*, where it expands and becomes much colder. This is then returned to the multi-tubular cylinder, thus producing the needed low temperature to liquefy the remainder of the CO in the ascending gases.



FIGS 9 AND 10—COMPARATIVE SIZE OF HABER AND CLAUDE INSTALLATIONS FOR HYDROGEN PURIFICATION
Two tubes of Fig 10 are sufficient to produce the same amount of pure hydrogen as the Haber installation shown in Fig. 9 (24,000 cu.m. per day)

The principal difficulty encountered was that at a temperature of —210 deg. C., needed to condense all of the carbon monoxide, there was no known lubricant which could be used to enable smooth working of the motor. This has been solved, however, by a very simple expedient. As the ultimate aim is to have the mixture of pure nitrogen and hydrogen, the introduction of nitrogen before the hydrogen entered the cylinder *M* is not at all harmful. This nitrogen is immediately liquefied after each expansion and the liquid nitrogen acts as a lubricant, since it freezes only at —210 deg. C. This very simple solution of the problem has been a very helpful step toward the practical success of the superpressure process. And so, instead of having an installation of the size shown in Fig. 9, merely two tubes of the size shown in Fig. 10 will be sufficient for the production of 24,000 cu.m. of pure hydrogen per day.

The problem of purification of hydrogen from coke-oven gas is solved in practically the same manner as has been described for water gas, and an apparatus installed at the coke plant of the Béthune Coal Co. now gives 800 cu.m. of pure hydrogen per hour. A plant is now being erected at this same works which will produce 3 tons of ammonia per day, using this source of hydrogen.

This, it would seem, is the beginning of the practical realization of Claude's plans to have a number of small plants located near the sources of cheap hydrogen and convenient for the cheap manufacture of the finished product (fertilizer).

It may be mentioned that as a byproduct of the operation for the extraction of pure hydrogen from coke-oven gas it will be possible cheaply and completely to extract both the benzol and ethylene.

Although the present variations in the foreign exchanges and labor costs render all figures quite empirical, it may be stated that according to Claude's claims the cost of installation per ton of synthetic ammonia by the superpressure process is less than half the cost when using t' Haber process. The relative simplicity of operation of Claude's process and the fact that it can be installed in small units are also to be taken into consideration.

of the commonest ideas is that it is due to grinding the wood in the mechanical pulp mill at too high a temperature, and this idea is put forward in one of the latest books on the pulp and paper industry. In the writer's opinion this idea is quite wrong, except in so far as a high grinding temperature tends to produce considerable flour stock and makes the pulp "slow." In the presence of pitch this fine stock is likely to be picked up by the soft pitch, causing immediate trouble, while a "freer" stock, ground at a lower temperature, would not be so likely to behave thus.

Apart from this it seems obvious that the mere mechanical operation of grinding wood on a stone, even at temperatures as high as 185 deg. F., cannot conceivably cause pitch trouble to originate. Theoretically, the higher the temperature of grinding the less should be the pitch trouble, as the higher temperatures would tend to split off volatile terpenes and modify the so-called rosin-fat which causes the trouble. In connection with this question of temperature of grinding, it is interesting to consider that in Norway about 15 years ago (if not now) both the "hot" ground and "cold" ground processes of making mechanical woodpulp were practiced side by side in the same mill, and the writer had the opportunity of observing these two processes in several of the Norwegian mills at that time. Samples of hot-ground and cold-ground pulp from these mills were extracted by ether, giving the results shown in Table II. The wood used in the Norway samples is believed to have been entirely Norway spruce, the chicoutimi sample being 90 per cent spruce and 10 per cent balsam, and the North Shore sample probably 100 per cent slow grown spruce.

TABLE II—ETHER EXTRACTION OF HOT AND COLD-GROUND PULP

Wood	Per Cent Ether Extract Hot Ground	Per Cent Ether Extract Cold Ground
Norway, *Honefos C*		0.37
Norway, *Vittingfos "V"*		0.35
Norway, *Honefos L*	0.35	
Norway, *Honefos A*	0.30	
Norway, *Vittingfos E*	0.50*	
Canada, *Chicoutimi V*	0.32	
Canada, *North Shore*	0.31	

* Probably an experimental error

There is not much comfort in these figures for the paper mill men who say that "hot" grinding causes pitch trouble. One would suppose from their argument that the hot-grinding process actually increased the pitch content of the ground wood. This latter is interesting when we consider sulphite pulp.

Another idea prevalent in the paper mill in times of pitch trouble is that balsam fir causes the trouble. This idea apparently is based on nothing more substantial than the fact that the bark of balsam exhibits much "Canada balsam"—a gummy deposit, noticeable by everyone. Of course all this bark is "rossed" off before the wood is used, so that theory seems scarcely logical. Again, jackpine has been frequently described as the offender in pitch troubles, with little more justification than in the case of balsam. The other tree or trees—namely, black and white spruce—which comprise the majority of the wood used, seem to have been hardly considered as a possible source of pitch trouble, yet we are told that the spruces contain rosin or pitch ducts, while balsam contains none. Jackpine of course is resiniferous.

Extraction Tests

By Soxhlet extractions of the various woods, first with ether and then with alcohol, we get somewhat different figures for the various woods. The figures of different experimenters do not agree very well. "Green" wood gives different figures from "seasoned" wood of the same species, and the amounts of ether-alcohol extracts vary with the particular part of the tree examined, so that no very definite figures can be given. Table III gives some figures obtained by the present writer.

TABLE III—SOLVENT EXTRACTION TESTS ON WOODS

Sample	Wood	Per Cent Ether Extract	Per Cent Alcohol Extract	Total Extract
1	White spruce (seasoned)	0.40	0.36	0.76
2	Black spruce (seasoned)	0.24	0.36	0.60
3	Balsam (seasoned)	0.85		
4	Balsam (green)	1.20	1.35	2.55
5	Balsam (punky) (rotten)	0.87	1.71	2.58
6	Jackpine (seasoned) (large tree)	2.70	0.99	3.69
7	Jackpine (green) (small tree)	3.24	1.71	4.95
8	Jackpine (river) (seasoned)	2.37	0.77	3.14

TABLE IV—SOLVENT EXTRACTIONS BY JOHNSEN AND HOVEY

Wood	Per Cent Ether Extract	Per Cent Alcohol Extract	Per Cent Total Extract
White spruce	0.516	0.473	0.989
Black spruce	0.32	0.367	0.687
Balsam fir	0.48	0.94	1.42
Jackpine	1.17	0.442	1.61

TABLE V—SOLVENT EXTRACTIONS BY RICHTER

	Ether Extract	Alcohol Extract
Fresh balsam	0.45—0.85	1.15—3.65
Fresh spruce	0.70—1.80	0.70—1.94

TABLE VI—ROSIN-FAT CONTENT OF PULP WOODS

Wood	Per Cent Total Resin	Per Cent Soluble in Petroleum Ether
Black and white spruce	0.80	56
Balsam	1.70	38
Jackpine	1.85	54

In reference to Table III, numbers 1, 2, 3 and 6 were sample slabs, cut from large trees by the forestry department and well seasoned in a dry atmosphere over a relatively long period. No. 4 balsam was a freshly cut 7-in. diameter log, cut 6 miles south of Shawinigan Falls and brought in by sleigh. No. 5 balsam was a 4½-in. diameter log grown in the Abitibi district and probably cut from dead standing timber, as it was badly deteriorated. This sample shows the effect of seasoning, in a decrease in ether soluble constituents and increase in alcohol-soluble substances. No. 7 was from a 5½-in. diameter jackpine, cut by the writer personally for the purposes of this investigation. It was cut in the bush, about 70 miles beyond La Tuque, on Sept. 26, 1922, and the extractions made within 3 days of the cutting. No. 8 was from a 5¾-inch jackpine log taken from the river on Oct. 5, 1922. This was evidently not "green" wood, as it contained only 20 per cent of moisture. Apparently it was seasoned wood, river driven for a short time. The figures therefore are comparable with those of No. 6.

Table IV gives a set of figures obtained by Johnsen and Hovey.

It will be noticed that there are quite large variations between the several sets of figures. On the whole, it might be judged from these figures that balsam and jackpine would most likely be the trees to give pitch troubles.

Referring back to the statement that so-called "pitch" contains about 50 per cent of "rosin-fat," which is the cause of pitch troubles and which is soluble in petroleum ether, we are led to consider Table VI, based on Johnsen and Hovey's figures. From these figures we

see that spruce extract has the highest rosin-fat content, followed closely by jackpine extract, and with balsam much the lowest of the three.

Table VII gives a series of extractions made on ground woodpulp during times of pitch troubles and also during normal operation. We see by this table that there was less ether-soluble rosin in the pulp during pitch trouble times than in the periods of normal operation.

TABLE VII—ROSIN-FAT CONTENT OF GROUND WOOD PULP DURING PITCH TROUBLE AND IN NORMAL OPERATION

Date	Per Cent Ether Extract		Per Cent Alcohol Extract	Per Cent Total Extract	Pitch Troubles
7/20/21	0 45				Yes
11/3/21	0 38	0 55	1 25	1 63	Yes
11/2/21	0 82		0 98	1 80	Yes
11/10/21	0 83		0 61	1 44	Nil
11/10/21	0 70		0 86	1 56	Nil
6/12/14	1 22				
6/13/14	0 55				
6/15/14	0 89	0 85			Absent
6/16/14	1 05				
6/17/14	0 38				
8/29/14	1 03				

Table VIII gives a series of extractions on sulphite pulp mainly during pitchy periods. Referring to Table VIII, No. 1 shows the figures for "green" wood from the river. No. 2 shows figures for partly seasoned wood from the log pile. The extracts in No. 2 are lower than in No. 1. No. 11 was the case mentioned above, where the pitch was found to consist very largely of brass fragments, from machine wire. The figures show a low amount of resin. The reason for pitch trouble in this case was the highly contaminated (with dirt) state of the stock running on to the paper machine and a badly adjusted machine wire. The figures of Table VIII show, on the average, higher extractions during pitchy days, but otherwise there is nothing particular to be learned from them. The figures for jackpine sulphite show large amounts of ether extractions, yet no pitch troubles were experienced, probably due to the fact that the wood was seasoned.

TABLE VIII—ROSIN-FAT CONTENT OF SULPHITE PULP

Test No.	Date	Description	Per Cent Ether Extract	Per Cent Alcohol Extract	Per Cent Total Extract	Pitch Troubles
1	6/1-10/15/20	Average B C P S	1 36	0 68	2 04

13	3/4/21	Jackpine B C P S	2 02	0 43	2 45	Nil

In the whole series of extractions given above for wood, ground wood and sulphite, there is little which points out the cause of pitch forming on paper machines. There have been a number of attempts at explanation by various people, some of the explanations being quite opposed to one another. Cooper states that the trouble originates in the acid system, due to leaks in the gas line, forming particles of calcium sulphate, around which the pitch forms. The present writer has never found excess SO_3 in the burner gases during pitch trouble times and has always held the opinion that the trouble originates in the sulphite pulp alone, to a certain extent irrespective of what species of wood is being cooked, and that only by certain modifications in the cooking process can this trouble be overcome.

Prevention of Pitch Troubles

It has been commonly taken for granted that balsam fir and jackpine are the original culprits, and few persons seem to have thought of spruce as a possible starting point, yet spruce is still the main factor in newsprint making. Wimmer[1] makes some very significant remarks in relation to pitch troubles, emphasizing the following:

1. Many mills using spruce for sulphite are bothered by pitch.
2. To avoid pitch trouble, allow wood to season properly and use hot water to wash stock.
3. It is proved that excessive heat in cooking destroys pitch entirely.
4. When using green or half dry wood (spruce) use a higher free SO_2 and less combined.
5. Use a specially high percentage of MgO in the lime.
6. Put all relief liquor down drain.
7. Arrange for special cooking, so as to reach a temperature of nearly 160 deg. C. before blowing.
8. Use felt covered riffler boards and change often.

These remarks, especially the ones relating to cooking at a high temperature, are most significant, as they are quite in line with what the present writer has found to be the case, working quite independently. Wimmer also stresses spruce as causing the trouble.

The figures in Table VIII show that the wood, in going through the sulphite cooking process, does not lose much of its "pitch" as expressed in ether and alcohol extracts. Lieber states that only about 4 per cent is actually removed in the cooking process, the remaining 96 per cent being left in the cellulose when it is blown out of the digester. This fact alone ought to indicate that it is the sulphite pulp and not groundwood pulp which causes pitch trouble. The writer has examined numerous batches of sulphite pulp during pitchy periods and frequently found relatively large quantities of pitch fragments.

Determining Proper Cooking Temperature

During the past summer pitch troubles were very bad at intervals and a strong endeavor was made to find a remedy. During an especially troublesome period it was noticed that a quantity of twisted and cracked spruce logs were coming from the river. Some of these logs showed much resinous deposit and one particular log, about 9 in. in diameter, was put on the log splitter and split lengthwise. The log had a long wind-crack down the length of the wood and this was filled with a sticky semi-liquid deposit of brown rosin, clearly showing where the pitch trouble was coming from. There was such a large quantity of this sticky deposit that it offered an excellent opportunity for extended investigation. To try the effect of variations in cooking temperature on the pitch, the writer inclosed numerous samples of this pitch in sealed glass tubes, with spruce wood chips and bisulphite cooking liquor and cooked these at varying temperatures.

The results of several of the experiments were most significant and it was found that the pitch remained soft and runny at temperatures up to nearly 300 deg. F. (149 deg. C.), but as this temperature was nearly reached, the pitch began to harden and at temperatures

[1]*Pulp and Paper Magazine* (Canada), vol. 15, No 19

between 150 and 155 deg. C. a decided modification took place in the previously runny pitch. This change, which resulted in a decided hardening of the resinous matter, probably was due either to a splitting off of volatile terpenes or to a drastic modification of the rosin-fat constituent. On opening the tubes it was found that the pitch had not only hardened very materially but had nearly lost its sticky quality. In a tube that had been kept at a maximum heat of about 145 deg. F. the pitch was, if anything, more sticky than when it was put into the tube.

These experiments showed conclusively that 150 deg. C., or about 302 deg. F., was a critical temperature for the pitch and suggested at once that temperatures not below these should be used in cooking if pitch trouble was to be avoided. Previous to this, the common practice in cooking had been to reach a maximum temperature of about 143 to 144 deg. C. In the light of the above experimental results, the cooking temperature was at once put up to a maximum of 150 to 155 deg. C., with the gratifying result that the pitch troubles in the paper mill showed a most conspicuous decrease, and that during the warmest and most pitchy month of the year—August.

It is suggested that to avoid pitch troubles, the following points be observed:

1. Throw aside all logs showing evidence of wind-cracks and showing resinous matter.
2. Bring the temperature of the cook before blowing to at least 150 deg. C. and preferably to 155 deg. C. for, say, half an hour to an hour. (Possibly less time would do.)
3. Keep the stock, whether groundwood, sulphite or machine stock, free from dirt, including such things as undissolved dyestuffs.
4. Keep the groundwood pulp as "free" as is possible in good practice.
5. Keep the temperature of the dilute stock running on the paper machine as low as is practicable.
6. Season all wood as far as is practicable.

SUMMARY

1. Groundwood pulp is probably never the starting point of pitch troubles.
2. Spruce wood and not balsam or jackpine is probably the first cause of pitch trouble.
3. Experiments carried out by the writer show that if pitchy pulp be raised to temperatures above 150 deg. C. in the digester, pitch troubles on machines are almost eliminated.
4. When using pitchy wood (green) the manner in which sulphite cooks are made, particularly as regards temperature, determines whether pitch trouble will occur or not.

Correction

In the Feb. 28 issue of *Chem. & Met.*, in an account of the recent national boll weevil meeting at Atlanta, Ga., we included part of the address on the arsenic and calcium arsenate shortage as having been delivered by "Howard Armbruster" of New York.

As will probably have been surmised by our readers, the author's correct name is Howard W. Ambruster, whose previous contributions to *Chem. & Met.*, will be remembered as having prophesied months ago the acute shortage of arsenic which finally developed as a result of the boll weevil situation.

Dealers Forbidden to Pose as Manufacturers

Progressive Action Taken in Paint Case by Federal Trade Commission

The Federal Trade Commission has recently decreed that a firm advertising as a manufacturer and not owning or controlling a factory is engaging in unfair competition. The American Turpentine Co., a firm trading under the name of the North American Fibre Products Co. and situated in Cleveland, Ohio, advertised in such a way as to indicate that its products (paints, varnishes, etc.) were manufactured in its own factories. Purchasers were thereby led to believe that they were saving the cost of a middleman.

On investigation, it was discovered that neither the American Turpentine Co. nor the North American Fibre Products Co. owned or controlled factories located in various cities throughout the United States, and that these factories listed in their advertisements were in reality those of manufacturers from whom they purchased goods for resale purposes. The commission has therefore issued an order that a firm must not advertise as a manufacturer unless factories are actually owned or operated by it.

Sulphur-Free Lye Used for Odorless Manufacture of Chemical Pulp

The majority of the cellulose industries in Sweden have adopted a newly invented method of producing cellulose, under the supervision of E. L. Rinman, according to a recent article in *Canadian Chemistry and Metallurgy*. Lyes are used that are free from sulphur, and chemical products of high value are produced from the organic substances that have been dissolved by the waste lye. The sulphate method uses sulphur-bearing lyes and consumes as fuel the organic substances contained in the waste lyes. In the actual production of cellulose, the two methods are not unlike. They differ essentially, however, in the comparison of the boiling solvent, as well as in the further treatment of the waste lye.

By the use of a sulphur-free lye, Dr. Rinman has succeeded in making the manufacture of cellulose entirely odorless, thereby overcoming a difficulty which countless efforts in the past have failed to remove. Moreover, considerable economic advantage results from the utilization of the large amount of organic substance, comprising from 50 to 60 per cent of the volume of the wood which normally escapes during the boiling of the cellulose and passes into waste lye.

Spontaneous Changes in Precision Balances

The Bureau of Standards has carried out successive tests on two of its highest grade analytical balances. These balances have been used constantly but with extreme care for some years. Both balances showed appreciable changes in the ratio of the arms of the beam which could not be explained as the result of wear of the knife edges. The bureau considers that these alterations are the effect of spontaneous changes in the beam, probably caused by the gradual release of stresses set up during the manufacture of the balance. This study corroborates evidence of such changes noted in many balances of this type and supports the long-established policy of recommending that analytical and similar balances be checked occasionally by the users.

Synopsis of Recent Chemical & Metallurgical Literature

Marketing of Chromite

The chemical industry is one of the large consumers of chromite, which it uses for the manufacture of sodium and potassium chromates and bichromates, chromium pigments and various derivatives used in tanning and dyeing. Edward Sampson, of the U. S. Geological Survey, in an article in the Feb. 24 issue of *Engineering & Mining Journal-Press*, makes the following statement regarding the industrial consumption of chromite:

"Recently one of the largest importers made an estimate for me of what he considered the present requirements of these industries. The following are his figures as compared with the 1918 estimate of the War Industries Board:

ESTIMATED CONSUMPTION OF CHROMITE, IN PER CENT OF TOTAL

	1918	1922
Ferrochromium	52	40
Refractories	17	35
Chemicals	31	25

"The 1918 estimate was on the basis of a consumption of 130,000 tons and the 1922 estimate is on the basis of a consumption of about 110,000 tons, which is probably too high."

Domestic sales, imports and apparent consumption of chromite in the United States in 1917 and 1917-21 are shown to have been as follows:

(In Long Tons)

Year	Domestic Sales	Imports	Apparent Available Supply
1913	255	65,180	65,435
1917	43,725	72,063	115,788
1918	82,430	100,142	182,572
1919	5,079	61,404	66,483
1920	2,502	150,275	152,777
1921	282	81,836	82,118

How Chromite Is Sold

Chromite is usually sold on yearly contract or in shipload lots. Sampling is by an independent chemist, and payment is made according to his report. The common terms are 75 per cent on arrival of steamer, and the balance on report of sampler.

The basis on which the price is fixed varies according to the use to which the ore is to be put. Ore for refractories is sold at a flat price with a guaranteed chromic oxide content—for example, 40 per cent, rejectable if below 38 per cent. A minimum quantity of silica is guaranteed in ore for refractory purposes—generally a minimum of from 5 to 8 per cent. Ore for ferrochromium and for chemicals is paid for according to the chromic oxide content. At present such ore is sold on the basis of 50 per cent Cr_2O_3, with an adjustment per unit above or below that figure. The unit is 1 per cent of Cr_2O_3 per long ton. During the war domestic chromite was sold on direct unit-price basis, the unit price varying according to the grade of the ore. The sale of chromite by the long-ton basis is a reflection of the fact that British interests have long controlled the market.

Nitrogen Distribution in Vertical Retorts

The problem of the reaction of nitrogen in coal during treatment in gas works is one of the important problems of the gas industry today. In the *Gas Age-Record* for Feb. 14, 1923, C. H. Stone, of the Rochester Gas & Electric Corporation, discusses the subject of the distribution of nitrogen in the products of carbonization obtained from vertical retorts.

It is stated that the subject of nitrogen is particularly important at the present time, due to the increased production of ammonia which follows on the increased use of the byproduct oven for gas production.

Yield of Ammonia

At present only 15 to 25 per cent of the nitrogen in the coal is recovered as ammonia, the remainder going mostly into the coke, partly into the tar, and partly into the gas. In the A.G.I. report for 1908 we find that for horizontal retorts 43.31 per cent of the total nitrogen in the coal goes into the coke as nitrogen; 2.98 per cent goes into tar as nitrogen; 15.16 per cent goes to liquor and gas as ammonia; 1.43 per cent goes to liquor and gas as cyanogen; and 37.12 per cent goes into the gas as nitrogen, or is accounted for as lost.

The *Journal* of the Society of Chemical Industry, vol. 23, page 581, states that the ammonia yield is 34 per cent more in vertical retorts than in horizontal, and the following table is given for the distribution of nitrogen:

N_2	Foster	Knoblauch	McLeod	Short
As NH_3	14.50	12-14	17.1	15.16
As CN	1.56	2.0	1.2	0 43
In coke	48 68	50 0	58 3	43 31
In tar			3 9	2 98
In gas	35 26	30 0	19 5	37 12

Yields by Various Processes

The following table gives some idea of the yield of ammonia from various methods of retorting coal. Of course the yield obtained varies from day to day with the kind of coal, with the heat used, with the amount and duration of the charge, with the amount of steam admitted, and other factors. This table gives also results from two horizontal retorts and one inclined retort in order to form a basis of comparison between the different types of retorts. Bolz in *Journal of Gas Lighting* gives the ammonia produced in per cent from different kinds of installations as follows:

Bolz	Dessau	Munich Chamber	Incl Retorts	Incl Retorts	Hor. Retorts
0.325	0 325	0 26	0 26	0.26	0.26

Inclines—Frank Huber, *Proc. A G L*, 1914, average for 13 years, NH_3, 5 002 lb

As shown by these figures, there is a wide divergence both in the yield of ammonia and in the distribution of the nitrogen in products of carbonization. For this reason it is necessary to make determinations of these figures for every individual installation, and with that fact in mind the author of this paper investigated the plant with which he is connected at Rochester, N. Y.

The Investigation at Rochester

The installation at Rochester consists of U.G.I. vertical retorts, each holding 1 long ton of coal. These retorts are ordinarily charged at intervals of 11¾ hours. The temperatures used are 2,300 deg. F. at the bottom and 1,600 deg. F. at the t' of the retort. The gas passes directly from the retort through the hydraulic main to a primary condenser of the Doherty washer-cooler type, in

Important Articles In Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department; but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

which it is cooled by a spray of weak ammonia liquor. It then passes to the exhauster, through a second washer-cooler, to the intensive scrubber, purifiers, light oil scrubber, feeder and holder.

The coal used at Rochester showed 1.75 per cent nitrogen and the coke showed 1.16 per cent. Therefore 0.94 per cent of the weight of the coal was the amount of nitrogen to be distributed among the products of carbonization. This is with an assumed make of 70 per cent coke. The total free nitrogen in the gas which came from the coal was 1.73 per cent by volume. Of the nitrogen in the products of distillation we find the following distribution:

	Per Cent Nitrogen by Weight
Lower hydraulic	
Liquor and tar contain as NH_3	0.10
Tar contains as CN	0.000007
Liquor contains as CN	0.00045
Upper hydraulic	
Tar contains as NH_3	0.13
And primary liquors contain as NH_3	1.37
Tar contains as CN	0.00048
And primary liquors contain as CN	0.016
Primary tar contains as NH_3	0.77
Primary tar contains as CN	0.00039
Gas contains as NH_3	21.94
Gas contains as CN	2.64
Gas contains as nitrogen	73.01

Calculating the ammonia from all sources, the results are as follows:

Total yield	Lb.
From coal	5.58
In gas at outlet of primary	976.47
In lower hydraulic tar and liquor	4.45
In upper hydraulic tar	5.91
In primary tar	34.44
In primary and upper hydraulic liquors	61.03
For the 12-hour test, all sources	1082.30
Now 0.94 per cent of the weight of coal is nitrogen, would yield	4441.00

so that we find 1082 × 100 ÷ 4441, or 24.4 per cent, of the possible ammonia yield was obtained. This shows pretty conclusively where there is room for improvement.

RESULTS FROM THE TEST

Incidental to the test the following was ascertained:

	Gal
Total tar and liquor from the lower hydraulic for 24 hours (*w*)	473.6
Total tar from the upper hydraulic for 24 hours (*x*)	5249.8
Total tar from the primary hydraulic for 24 hours (*y*)	2555.4
Total liquor from primary and upper hydraulic for 24 hours (*z*)	1317.6
Grains of ammonia per gal in (*w*)	151.5
Grains of ammonia per gal in (*x*)	15.8
Grains of ammonia per gal in (*y*)	188.7
Grains of ammonia per gal in (*z*)	648.4

From the study several conclusions may be drawn:

1. About one-half of the nitrogen in the coal goes into the coke.
2. Of the remainder nearly three-quarters goes into the gas as nitrogen.
3. The total ammonia recovered is only about one-quarter of what it might be if all of the nitrogen in the products of distillation were made into ammonia.
4. Most of the cyanogen goes off with the gas.
5. There is but little cyanogen in any of the liquors or tars, at least in those prior to the secondary condenser.

As for the ammonia, it is clear that a large part of the nitrogen of the coal not only goes to waste, but does actual damage in lowering the calorific value of the gas. It is believed that a method can and will be devised whereby a much larger percentage of the nitrogen will be recovered as ammonia, which will provide needed materials for other manufacture. In conclusion, the author states that no account has been taken of nitrogen in organic combinations other than cyanides. He states that he believes this amount to be too small to be of consequence, but that he will examine into the matter later.

Ingot Defects in Acid Open-Hearth Steel

F. Pacher presents a lengthy review of the problem of sound ingots in *Stahl und Eisen*, 1922, vol. 42, pp. 485-492, 533-540 and 537-577. The sources of defects due to tapping, ingot molds, casting and the character of solidification are enumerated. Some interesting experiments on water and oil mixtures are noted, and certain deductions bearing on the behavior of molten steel and slag are discussed. The respective advantages of top-pouring and of bottom-casting are given. At the moment top-casting is finished, the metal at the top of the mold is the hottest—that circumstance favors the soundness of the ingot. On the other hand, the metal rises more slowly when bottom-casting, and a cleaner skin is generally obtained; these advantages, however, are bought at a price, and the dimensions of the ingots are to be taken into account if they are to be realized.

During the solidification period the steel is subject to dangers arising from uneven temperature conditions and from mechanical forces; thus the quality of the best-melted steel may be seriously impaired. The most serious danger lies in the piping, which is usually accompanied also by axial sponginess and by contraction cavities and cracks. In practice an effort is made to pour at the correct casting temperatures; conditions insuring that temperature will incidentally help to lessen the piping area.

The chemical composition of steel plays an insignificant rôle when compared with changes which result from defects arising during casting and cooling down of the ingot. Therefore every means must be taken to avoid these defects and to obtain sound ingots.

Influence of Phosphorus on Brasses

A. Portevin has discussed this question before the Nancy Congress of the Technical Foundry Association of France. The question having been put to him whether any deleterious effects may result from the presence of phosphorus in cast brasses, two series of alloys with increasing amounts of phosphorus were prepared and tested. In the first series (α brass) the copper content was about 68 per cent, in the second ($\alpha + \beta'$ brass) about 58 per cent. Both sand-cast and chill-cast bars were tested. The results tabulated in the paper show that up to 0.05 per cent phosphorus does not affect the mechanical properties in any considerable degree; on the contrary, if 0.50 per cent is reached, a considerable decrease in resilience and in elongation after rupture occurs.

Microscopical investigations show that phosphorus is responsible for the occurrence of a new constituent, most probably the phosphide Cu_3P. This constituent appears in the first series when the percentage of phosphorus reaches 0.05 per cent, and in the second series after 0.50 per cent. These figures may be taken to represent the solubility of phosphorus.

The velocity of cooling does not seem to affect the rate of separation of the phosphides, neither does it alter the relative amounts of α and β' in the second series of alloys.

It follows that up to the content of 0.05 per cent, phosphorus would not cause any inconvenience in brasses; it will, however, be different with higher amounts.

In his concluding remarks the author draws attention to the fact that phosphorus will not act as a deoxidizer in brasses, as the heat of formation of the oxide of zinc is greater than that of phosphorus, and consequently the former will remain in solution even in the presence of phosphorus. For its elimination more powerful deoxidizers, like magnesium or aluminum, would be needed.

Reclamation of Used Petroleum Lubricating Oils

In Technologic Paper 223 of the U. S. Bureau of Standards, Dr. W. H. Herschel and A. J. H. Anderson describe a series of tests with an apparatus for reclaiming oil which has been subjected to severe conditions of service. By the use of a coagulant it was found that reclaimed oils could be obtained which would stand the usually accepted tests such as viscosity, flash point and sediment, although the flash point was slightly lowered. The authors do not regard the tests as conclusive in regard to the efficiency of the process in reducing the organic acidity, since the oils they used had not been in service long enough to become very acid. The necessity of reducing this acidity to a low value is, however, open to question, since there appears to be no danger that the acidity would ever become high enough to cause corrosion, except perhaps of lead and zinc. The cause of sludge formation in a used lubricating oil is not at all clear, but it appears to differ from an emulsion in requiring considerable time for its development. As an oil continues in use for some time it accumulates dust, carbon and other materials in a finely divided state, and the most probable explanation appeared to be that the sludge is a case of a permanent emulsion due to carbon or dust in a colloidal condition. However this may be, it is evident that all finely divided as well as coarse impurities should be removed from used oils in reclaiming them.

Recent Chemical & Metallurgical Patents

Converting Formates Into Oxalates—According to the invention described in this patent, the formate is converted directly into the oxalate without the addition of any foreign substance, in the presence of air, and by simply and efficiently arranging and controlling the heat zones to which the formate is subjected. The apparatus in which this reaction is carried out provides for passing the formate through a preliminary heating zone by which it is rendered plastic and then subjecting it to heat not greater than 220 deg. C., by which the formate is rendered molten. At this temperature the formate is stable and there is no liability that it will be converted into carbonate. Having slowly raised the temperature of the formate to 220 deg. C., the liquid formate is then suddenly raised to the temperature necessary to drive off its molecule of hydrogen—i.e., to a temperature between 360 deg. C. and 440 deg. C. This is accomplished by spreading the liquid formate thinly over hot surfaces at the requisite temperature. By this means the liquid formate is converted into oxalate almost instantly—that is to say, the conversion does not take more than 2 or 3 seconds. From this brief outline of the process it will be recognized that the quantity of carbonate produced is negligible. The great difficulty heretofore existing in the manufacture of oxalate from formate has been to raise the temperature to the point at which it converts the formate into oxalate so rapidly that carbonate formation will be prevented (1,445,162; Herman W. Paulds, assignor to Royal Baking Powder Co. Feb. 13, 1923.)

Preventing Evaporation of Stored Liquids—Among the more important patents affecting the petroleum industry is one recently granted to Frank A. Howard, George H. L. Kent and James M. Jennings, covering the invention of a foam or foam-producing liquid intended to float upon the surface of volatile liquids such as crude petroleum, gasoline and the like, for the purpose of preventing evaporation. The foams described are permanent or stable in character—that is, they do not break down for a considerable storage period. They retain their fluent condition during their entire life, or they may be such as to congeal or solidify at ordinary atmospheric temperatures.

The liquid base for the preparation of a foam in accordance with the present invention may contain from 5 to 15 per cent of water, although preferably between 5 and 8 per cent. From 3 to 10 per cent of glue is incorporated in the liquid together with 5 to 15 per cent of cornstarch or an equivalent starchy material. Glucose or an equivalent material, such as blackstrap molasses, and glycerine are incorporated in the liquid, the combined proportion of these added constituents being from 40 to 80 per cent. From 4 to 8 per cent of calcium chloride is included in the mixture. Apparently this increases its tensile strength at low temperatures. A suitable setting agent, such as ferrous sulphate, is incorporated in the extent of from ½ to 2 per cent. From ½ to 1½ per cent of a suitable foaming agent, such as the sodium salt of sulphonic acids obtained from mineral oil sludge, may be incorporated, together with a suitable preservative as desired.

An example of a suitable foam-forming liquid, prepared in accordance with this patent, would be as follows: glucose, 50 per cent; glycerine, 24 per cent; cornstarch, 10 per cent; calcium chloride, 5.5 per cent; glue, 3 per cent; ferrous sulphate, 0.1 per cent; sulphonic acid salt, 1 per cent, borax, 1 per cent, and water, 5.4 per cent. (1,443,538; assigned to the Standard Development Co. Jan. 30, 1923.)

Nitrocellulose Composition—Hans T. Clarke has discovered that a nitrocellulose composition of desirable properties can be obtained by compounding cellulose nitrate with the salicylates of the higher aliphatic alcohols, such as normal butyl salicylate, amyl salicylate and isobutyl salicylate. The ingredients are combined by the use of a common solvent.

He incorporates in 400 to 600 parts of an acetone and methyl alcohol mixture, 100 parts of nitrocellulose, 20 to 60 parts of fusel oil, normal butyl alcohol, isobutyl alcohol and 1 to 70 parts of normal butyl salicylate. The ingredients are of commercial grades,

American Patents Issued Feb. 27, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem & Met.* readers. They will be studied later by *Chem. & Met.'s* staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,446,461—Method of and Apparatus for Measuring Gas. Charles W. Hinman, Winchester, Mass; Nathaniel C Nash, Jr, executor of said Charles W. Hinman, deceased.

1,446,480—Process and Apparatus for Fume Control. Robert S Perry, New York, and Paul W. Webster, Pelham Manor, N. Y, assignors to Perry & Webster, Inc, New York.

1,446,546—Method and Apparatus for the Fixation of Nitrogen. Charles H Buettner, Cincinnati, Ohio

1,446,550—Process of Removing Impurities From Resorcin. Thurston N. Dissosway, Flatbush, N. Y., assignor to Dissosway Chemical Co., Inc., Brooklyn, N. Y.

1,446,551—Process of Purifying Resorcin. Thurston N. Dissosway, Brooklyn, N. Y., assignor to Dissosway Chemical Co., Brooklyn, N. Y.

1,446,578—Process of Making Sulphates. Harry Pauling, Berlin, Grunewald, Germany.

1,446,606—Process and Apparatus for Extraction of Oils From Vegetable Matter. Matthew Whitehead, Kingston-upon-Hull, England, assigor of one-half to Ernest Scott, Kingston-upon-Hull, England

1,446,637—Manufacture of Lithopone. Frank G. Breyer, Palmerton, and Clayton W. Farber, Bowmanstown, Pa., assignors to the New Jersey Zinc Co., New York.

1,446,651—Continuous Evaporator for Vegetable and Fruit Pulps. Fernando C. Marzo, Placentia, Calif.

1,446,736—Manufacture of Hydrogen and Oxygen. Farley Granger Clark, Toronto Ont., Canada.

1,446,737—Treatment of Raw Rubber and Like Plastic Substances. Samuel Cleland Davidson, deceased, late of Belfast, Ireland, Alfred Agar, Holywood, Ireland, and Hugh Taylor Coulter, Belfast, Ireland, executors.

1,446,778—Process for Electrical Precipitation of Suspended Particles From Gases. Gustav A. Witte, Philadelphia, Pa, assignor to International Precipitation Co. Los Angeles, Calif.

1,446,818—Production of Diarylguanideno. John Young, Caldwell, N. J., and Elmer G. Crookman, Buffalo, N. Y., assignors to National Aniline & Chemical Co, Inc, New York.

1,446,844—Drying Kiln. Alexander R. Duff, Toronto, Ont., Canada.

1,446,863—Gypsum Calcining Apparatus. Sheldon E. Townley, East Orange, and Frederick E. Townley, Newark, N J

1,446,872—Process of Making Organic Oxides. Benjamin T Brooks, Bayside, N. Y.; assignor to Chadeloid Chemical Co, a corporation of West Virginia

1,446,873—Process of Making Chlorhydrins of Organic Liquids. Benjamin T Brooks, Bayside, N. Y., assignor to Chadeloid Chemical Co., a corporation of West Virginia.

1,446,874—Process of Dehydrating Chlorhydrins. Benjamin T. Brooks, Bayside, N. Y., assignor to Chadeloid Chemical Co., a corporation of West Virginia.

1,446,888—Method of Treating Fibrous Material. Eduard Dyckerhoff, Blumenau, Germany.

1,446,933—Process for the Manufacture of Black Carbonaceous Pigment. Vernon H. Schnee, Ithaca, N. Y.

1,446,953—Process for the Recovery of Tin and Iron Products From Tinned-Iron Waste. Harry V. Welch, Los Angeles, and Walter A Sheek, Long Beach, Calif assignors to International Precipitation Co., Los Angeles, Calif.

1,446,984—Method of Revivifying Spent Catalysts and Apparatus Therefor. Thomas Midgley, Jr., Dayton, Ohio, assignor, by mesne assignments, to General Motors Research Corporation, Dayton, Ohio

1,447,008—Fuel and Method of Producing Same. Lindon W. Bates, Mount Lebanon, N. Y.

1,447,014—Ejecting Apparatus for Exhausting Air or Other Fluids. Raymond N. Ehrhart, Pittsburgh, Pa., assignor to Elliott Co., Pittsburgh, Pa.

1,447,052—Method and Apparatus for Removing Liquid and Salt Deposits From Gas Wells. Michael M. Sweetman, Kansas City, Mo.

1,447,128—Self-Regulating Ammonia-Making Process. Luigi Casale, Rome, Italy, assignor to Casale Ammonia Co., Lugano, Switzerland.

1,447,143—Manufacturing of Lead Alloys. Walther Mathesius, Charlottenburg, Germany.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

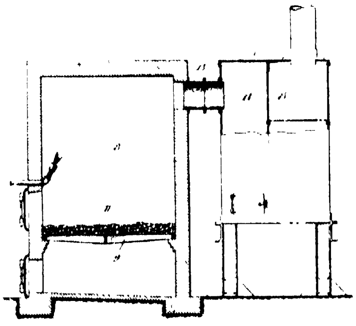
having sufficient purity to provide the necessary transparency and comparative freedom from color required by the finished film. The ingredients are thoroughly mixed and filtered if desired. The film made from this solution still contains the higher alcohols in part with the nitrocellulose and butyl salicylate, and these have the effect of enhancing the stability of the film as well as increasing its flexibility. (1,444,333; assigned to the Eastman Kodak Co. Feb. 6, 1923.)

Cellulose - Ether Composition — In order to provide a solvent which will dissolve such large proportions of cellulose ethers that thick or viscous solutions may be obtained for use in plastic and film-making arts, and also to provide a cellulose-ether solution which may be manufactured into a strong, flexible, transparent film, Stewart J. Carroll has secured a patent for a special combination of solvents. He has discovered that a satisfactory and useful solvent may be prepared by mixing various alcohols with phenyl propyl alcohol. For instance, he combines methyl alcohol, ethyl alcohol, propyl alcohol, isopropyl alcohol, butyl alcohol (normal, iso or secondary) and fusel oil or the amyl alcohols, either singly or in various mixtures, with phenyl propyl alcohol. The proportions may be very greatly varied in a very useful range, from 50 to 10 parts by weight of alcohol mixed with 50 to 90 parts of phenyl propyl alcohol. The patent points out that the phenyl propyl, being of comparatively low volatility, remains in considerable amounts in the film and imparts useful properties to it. (1,444,331; assigned to Eastman Kodak Co. of Rochester, N. Y. Feb. 6, 1923.)

Cellulose-Ether Composition—A patent designed to accomplish somewhat the same object as outlined in the patent just described (1,444,331) has been granted to William R. Webb and assigned to the Eastman Kodak Co. In the process described in this patent a cellulose-ether such as water-insoluble ethyl cellulose is dissolved in a mixture of ethylene chlorhydrin and methyl alcohol or other lower monohydroxy aliphatic alcohol. The proportions recommended are 1 part of ether to 4 to 6 parts of ethylene chlorhydrin. (1,444,406. Feb. 6, 1923.)

Manufacture of Anthraquinone and Phthalic Anhydride—Heretofore one of the principal methods of preparing anthraquinone has been by the high-temperature catalytic air oxidation of anthracene, the anthracene being in more or less high state of purity—that is to say, it contained from 70 to 100 per cent of anthracene. It is now reported that anthraquinone can be produced efficiently from anthracene press cake by the oxidation of the anthracene in the press cake; that phthalic anhydride is produced at the same time by the oxidation of the phenanthrene in the press cake; and that the carbazol present in the press cake may be recovered by prior separation before the substances are passed over the catalyst. Or, if desired, the carbazol may be allowed to remain and a large proportion of it passes over the catalyst unchanged and can be recovered along with the products of oxidation. The catalyst used for this operation consists of vanadic oxide, although oxides of molybdenum or chromium may be employed. (1,444,068. H. D. Gibbs, assignor to E. I. du Pont de Nemours & Co. Feb. 6, 1923.)

Recovery of Potash From Distillery Waste—Carl Haner, Jr., of Baltimore, has assigned to the U. S. Industrial Alcohol Co. a patent for recovery of potash from the distillery waste or slop left after the alcohol has been separated from the alcohol producing material. As indicated in the diagram, the distillery waste is forced through nozzle 1 into the heated chamber 8. The chamber is originally heated by means of a bed of coal labeled 11. Later the process is self-supporting as far as heat is concerned. Potash separates as an



ash from the burning waste and falls to a large extent through the grate bars 9 and is collected in the clean-out pit. The gases pass through pipe 13 into a chamber 14, down which the gases are forced by means of a baffle plate 15. The potash which remains in the flue gases is thus separated out here and cleaned out occasionally through the clean-out doors. It will be noted that the waste is sprayed upward in the combustion chamber and furthermore during the operation the grate bars must be raked with a rabble to facilitate the passage of the potash. (1,444,833. Feb. 13, 1923.)

Refractory—As a lining for heating furnaces in general, and for electric furnaces in particular, Charles A. Scharshu has patented and assigned to the General Electric Co. a refractory consisting of a mixture of crystallized magnesia, calcined magnesia and a carbonaceous binder, heated to from 1,700 to 1,800 deg. C. under conditions permitting elimination from the surface of the carbon residue resulting from decomposition of the binder. The mass is thus converted into a sub-vitreous condition by condensation of sublimed magnesia in intercrystalline spaces.

It is claimed for a refractory lining made in this way that it may be used without appreciable softening at the highest temperatures used in electric steel furnaces and at these temperatures the lining is converted into a mass so hard that it has a metallic ring at operating temperatures. It is also claimed that the lining so made has great resistance to chemical action of slags even at the highest temperatures. This lining is strong mechanically and has not cracked or deteriorated under an almost indefinite number of furnace runs. There is no expansion or contraction at temperatures up to 1,800 deg. C. (1,444,527. Feb. 6, 1923.)

Solidifying Materials—This invention is for the purpose of solidifying various materials, more particularly those which change during the process of manufacture from a viscous condition to a crystalline condition with the evolution of heat. Materials of this kind are combined by boiling the ingredients in a container and the resulting mixture is then permitted to cool. Due to the evolution of heat during the process of crystallization, a great deal of time is necessary for the cooling to take place, and with some mixtures such a high temperature is reached that the mass fuses and becomes difficult to grind. Also, if allowed to solidify in large masses, the material becomes difficult to remove from the containers.

The objects of the present invention are to expedite the crystallization of the material, to enable it to be easily ground, to eliminate much of the work incident to removing the material from the container and generally to simplify the process.

The method employed is as follows: The material while in liquid form is spread in a thin layer on a cooling surface in the form of a drum. It remains on this surface until cool and in a viscous condition. The drum is cooled by the circulation of a cooling medium through its interior. It is revolved by mechanical means and in the course of its revolutions a scraper removes the viscous material from its surface at the desired point. After the material is removed from the cooling drum it is spread out on a traveling belt, on which the crystallization takes place. Since the material is in the form of a thin layer on this belt while the crystallizing process is under way, the heat evolved is readily dissipated, hence shortening the time required for solidification. The conveyor is made sufficiently long for the crystallization to take place completely, and at the end of the conveyor the crystallized material is dumped off into a bin, hopper, car or wherever may be desired. (1,445,004. Edwin Cowles, assignor to the Electric Smelting & Aluminum Co., of Lockport, N. Y. Feb. 13, 1923.)

Pure Liquid Hydrocyanic Acid—W. G. Dingle was awarded patent 1,304,745 dated May 27, 1919, relating to the preparation of crude liquid hydrocyanic acid. The present patent deals with the production of pure liquid hydrocyanic acid. This is accomplished by condensing the gas to liquid form and reconverting it into gas before it is finally condensed. (1,445,303. Feb. 13, 1923.)

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

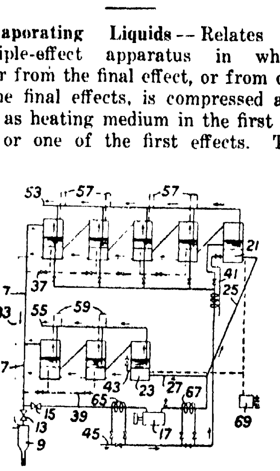
Treating Silicates—Insoluble minerals containing alkali metals, such as feldspar, are heated with fusible salts at a temperature not higher than about 650 deg. C., or less if the heating is effected under pressure. The reaction mixture is extracted with water and the soluble alkali salts separated in known manner. Suitable fusible salts mentioned are the chlorides of calcium, barium, iron, zinc, manganese and aluminum; magnesium sulphate; and barium nitrate. Mixtures of these salts may be employed. In an example, 100 parts of ground feldspar are heated with about 200 parts of calcium chloride at a temperature of 650 deg. C., and the resultant mass extracted. Hydrated calcium chloride may be used if the heating is effected under pressure. (Br. Pat. 188,454. Plauson's, Ltd., London. Dec. 30, 1922.)

Cellulose Ethers—The inventor proposes to reduce the quantity of water present during etherification by addition of dehydrating compounds, in amounts preferably less than half the weight of the cellulose. The amount of caustic alkali or other base used in the etherification is at least equal to and preferably exceeds in the ratio of 3:1 to 10:1 or more the weight of water present or added. By the use of such water-binding agents, the alkali is more firmly seated on or united to the cellulose, and the etherification may be carried out with reduced quantities, even down to theoretical quantities, of alkali and etherifying agent. Suitable water-binding agents are the oxides of the alkali and alkaline earth metals, the hydrides of calcium and magnesium, the metals calcium, barium and sodium, and sodamide and sodium ethylate powder.

The compounds formed by the union of the water-binding agent with the water present may constitute in part or wholly the alkali or base necessary for the etherification; the hydroxides of the alkaline earth metals may be employed as the base, but with these, being weaker, the etherification may be conducted at temperatures higher than those necessary with the caustic alkalis.

In order better to control the temperature during the removal of the water, the water-binding agents are preferably incorporated in the presence of diluents or solvents such as benzol, toluol, carbon tetrachloride, ether, ligroin or benzene, and the mixture is strongly cooled; the solvents or diluents may also be employed during the etherification. The initial material is either cellulose or a near conversion product insoluble in dilute alkali at ordinary temperatures, or alkali-soluble cellulose derivatives from which such alkali-insoluble cellulose or conversion products may be reconstituted, or such reconstituted products themselves. In examples, cellulose impregnated with water is kneaded with sodium oxide either alone or with an addition of caustic soda and preferably in the presence of a diluent such as benzol, while cooling strongly, and to the mass which contains either no water or a very reduced quantity, diethyl sulphate is added, the temperature being maintained at 60 to 80 deg. C., or even at ordinary temperature or lower; instead of diethyl sulphate the corresponding methyl ester may be used, the temperature in this instance being maintained at 0 deg. C. or lower, for example, at —5 to —10 deg. C.; cellulose impregnated with water and caustic soda is kneaded with calcium oxide, preferably in the presence of benzol, etc., while strongly cooling, and the etherification is effected by the addition of diethyl sulphate with or without the addition of a further quantity of solid caustic soda, the temperature in this instance being between 60 and 130 deg. C. Alternatively, the water-binding agents may be added partly or entirely during the etherification. Specifications 12854/12 and 6035/13 are referred to. (Br. Pat. 187,639. H. Dreyfus, London. Dec. 20, 1922.)

Evaporating Liquids—Relates to multiple-effect apparatus in which vapor from the final effect, or from one of the final effects, is compressed and used as heating medium in the first effect or one of the first effects. The



energy required for the compression is derived from a natural direct source of mechanical energy, such as a fall of water, and heat losses are made up by steam from an electrically heated boiler, the energy for which is derived from the same source. The ordinary steam supply and condensing arrangements are retained in order that the amount of evaporation effected by the steam and by the energy of compression may be varied. Liquid is added to the vapors before or after compression, so as to absorb the superheat and generate makeup vapors. As applied to the apparatus described in specification 187,-260, in which a number of multiple-effect plants with overlapping temperature ranges are used and in which the final effects of each plant are connected to a main 7 which leads by a valve 13 to a condenser 9, a branch pipe provided with a valve 15 leads to a compressor 17, the compressed vapors being led by pipes 25, 27 to the heating spaces 21, 23 of the first effects of each plant. The condensates from each effect are cooled by flashing off vapor into effects at lower pressures and pass by a main 33 to the condenser 9. The liquid to be evaporated fed through a pipe 45 may be preheated in coils 65, 67 by the vapor before or after compression and by non-condensible gases withdrawn from the heating spaces of the first effects of each plant by valved pipes 41, 43. Non-condensible gases from the later effects are withdrawn by pipes 37, 39 leading to the main 7. The liquid to be evaporated is fed in parallel to the effects of each plant and the concentrated liquid is withdrawn in parallel through pipes 53, 55, vapors being flashed off to cool the liquid by connections 57, 59 to effects at lower pressures. Steam may be supplied to the heating spaces of the first effects from an electrically heated boiler 69. (Br. Pat. 188,703. T. Rigby, Westminster. Jan. 10, 1923.)

Preventing Incrustation and Corrosion—To prevent or reduce the corrosive or fouling action of water on the walls of a boiler or on brass, copper, tin, rubber, glass, earthenware and the like, a mixture of one or more soluble chlorides and one or more soluble chromates or bichromates is added to the water. Sodium, potassium, ammonium or zinc chromate is preferably used. (Br. Pat. 188,778. E. R. Jones and W. S. Smith, Westminster. Jan. 10, 1923.)

Ferric Oxide Absorbent Gel—Ferric oxide is prepared in a form suitable for use in the absorption or adsorption of condensible gases and vapors. A ferric hydroxide gel precipitated from a ferric salt solution is washed, filtered, pressed and dried slowly, first at a moderate temperature and then at a higher temperature. The hydroxide gel is preferably precipitated from a concentrated ferric salt solution by means of a dilute caustic alkali or alkali-carbonate solution, the precipitant being slowly added to the ferric salt solution, with agitation, until a thick paste is obtained. The precipitate is washed with water containing small amounts of dissolved matter, filtered and pressed into slabs or extruded through holes in a die. The first drying is effected slowly at a temperature of 26 to 36 deg. C., a hard brittle product being obtained. The second drying is accomplished either in a current of air at a temperature of 110 to 160 deg. C., or in a vacuum, in which case the temperature is preferably raised slowly from 100 to 160 deg. C. and may afterward be slowly increased to 250 deg. C. (Br. Pat. 188,786. B. Lambert, Oxford. Jan. 10, 1923.)

Phenylglycine—Phenylglycine is obtained from trichlorethylene and aniline by a modification of the process of specification 173,540. One molecular proportion of trichlorethylene is slowly pumped into a mixture of slightly more than one molecular proportion of aniline and a base such as milk of lime at 170 to 180 deg. C. An example of the method is given, the phenylglycine salt obtained being worked up in the usual manner. (Br. Pat. 188,933. British Dyestuffs Corp., Ltd., and M. Wyler, of Blackley, Manchester. Jan. 10, 1923.)

World Petroleum Output Shows Increase in 1922

American Petroleum Institute Estimates 11 Per Cent More Production Than in Previous Year

Mexican Official Figures Show Drop

THE American Petroleum Institute estimates the world's petroleum production in 1922 at 851,540,000 bbl., compared with 765,065,000 bbl. reported by the U. S. Geological Survey for 1921. The increase in 1922 amounted to 84,475,000 bbl., or 11.3 per cent.

The United States produced 551,197,000 bbl. in 1922, or 64.7 per cent of the total world production. In 1921 the United States produced 472,183,000 bbl., or 61.7 per cent of the world production in that year. The increase in the United States production in 1922 amounted to 79,014,000 bbl., or 16.7 per cent. Mexico produced 185,057,000 bbl. in 1922, amounting to 21.7 per cent of the world production. In 1921 Mexico produced 193,397,587 bbl., or 25.3 per cent of the total production that year. The decrease for Mexico in 1922 amounted to 8,340,587 bbl., or 4.3 per cent. In 1922 the United States and Mexico combined produced 86.4 per cent of the world production and in 1921 87.0 per cent. Substantial increases in production in 1922 are shown by Persia, Peru, Sarawak, Argentina and Venezuela, while Colombia showed its first commercial production.

Wherever possible 1922 production figures are official final figures or official estimates. In converting the figures of certain countries from tons to barrels, equivalents are stated in United States barrels of 42 gal., based upon the average specific gravity of the oil of each country. All the figures shown for 1921 are those reported by the U. S. Geological Survey.

Estimated World Petroleum Production	1922, Bbl	*1921, Bbl
United States	551,197,000	472,183,000
Mexico	185,057,000	193,397,587
Russia	35,091,000	29,150,000
Persia	21,154,000	16,672,540
Dutch East Indies	16,000,000	16,958,105
Roumania	9,817,000	8,368,000
India	7,980,000	8,000,000
Peru	5,332,000	3,699,280
Poland (Galicia)	5,110,000	5,167,000
Sarawak	2,915,000	1,411,000
Argentina	2,674,000	1,747,410
Trinidad	2,445,000	2,354,000
Venezuela	2,335,000	1,433,000
Japan and Formosa	2,004,000	2,447,000
Egypt	1,188,000	1,255,000
France	494,000	392,000
Colombia	323,000	
Germany	200,000	200,000
Canada	179,000	190,338
Italy	31,000	34 400
Algeria	9,000	2,688
Others	5,000	2,652
Total	851,540,000	765,065,000

* Figures for 1921 are those of the U S Geological Survey.

The Institute estimates that the daily average gross crude oil production in the United States for the week ended March 3 was 1,795,400 bbl., as compared with 1,784,700 bbl. for the preceding week, an increase of 10,700 bbl. The daily average production east of the Rocky Mountains was 1,165,400 bbl., as compared with 1,154,700 bbl., an increase of 10,700 bbl. California production was 630,000 bbl., the same as the previous week.

The following are estimates of daily average gross production for the weeks ended March 3, Feb. 24, 1923, and March 4, 1922:

Daily Average Production
(Figures in Barrels)

	1923 Mar. 3	1923 Feb 24	Difference	1922 Mar. 4
Oklahoma	414,400	406,550	Inc 7,850	345,500
Kansas	80,600	80,950	Dec. 350	82,000
North Texas	51,100	50,250	Inc 850	50,850
Central Texas	120,550	124,050	Dec 3,500	205,150
North Louisiana	71,300	70,750	Inc. 550	116,500
Arkansas	105,600	103,750	Inc 1,850	34,300
Gulf Coast	104,450	106,450	Dec 2,000	107,950
Eastern	108,000	107,000	Inc. 1,000	110,000
Wyoming and Montana	109,400	104,950	Inc. 4,450	57,800
California	630,000	630,000		310,000
*Total	1,795,400	1,784,700	Inc. 10,700	1,420,050

* Daily average production.

The total production of petroleum in Mexico during the year 1922 was 185,057 249 bbl., a decrease of 9,698,463 bbl. from the previous year, when the total production was 194,755,712 bbl., according to figures compiled by the Mexican Service Bureau from the official documents of the Secretaria de Hacienda y Credito Publico.

Of the total 46,763,959 bbl. was produced in the Tampico district, an increase of 4,653,302 bbl. over the previous year, and 138,280,924 bbl. in the Tuxpam district, a decrease of 14,362,098 bbl. from the previous year. In addition to these two fields, the Mexican Eagle produced 12,366 bbl. in the Isthmus. The production of the Tuxpam-Isthmus zones is light oil and that of Tampico is heavy oil, with the exception of 1,450,279 bbl. of heavy oil produced in the Tuxpam district by well No. 2, Molino, of the Penn-Mex. Fuel Co. and wells Nos. 2 and 6, San Gerenimo, of the Mexican Eagle.

The largest producer was the Huasteca Petroleum Co., with 55,604,871 bbl., all of which was light oil and represents 30 per cent of the entire Mexican production. This is an increase of 26,140,165 bbl. over the previous year, or 88.7 per cent (in addition the Mexican de Pretroleo, South America, another subsidiary of this company, produced 1 833,554 bbl. of heavy oil). This is a remarkable showing in view of the fact that the entire production was in the south fields, where there has been a considerable amount of salt water invasion.

The exports from Mexico for the year 1922 were 180,872,239 bbl., an increase of 8,557,907 bbl. over the previous year, when 172,304,332 bbl. was exported. This increase of exports was due in a large measure to the increased production of Huasteca Petroleum Co. and the drawing of oil from storage by the other companies. The largest exporter was the Huasteca Petroleum Co., with 39,508,879 bbl., which consisted mainly of 32,315,793 bbl. of fuel oil and 5,892,654 bbl. of crude gasoline.

Calendar

The following important technical meetings are scheduled for the immediate future:

AMERICAN CHEMICAL SOCIETY
New Haven, Conn., April 3-7

AMERICAN FOUNDRYMEN'S ASSOCIATION
Cleveland, O., April 28-May 1

AMERICAN OIL CHEMISTS' SOCIETY
Hot Springs, Ark., April 30-May 1

SOCIETY OF INDUSTRIAL ENGINEERS
Cincinnati, O, April 18-20

SOCIETY OF CHEMICAL INDUSTRY
New York, regular meeting, March 23

SOCIETY OF CHEMICAL INDUSTRY
New York, joint meeting with other societies, April 20

S.O.C.M.A. Annual Meeting Hears Herty and Garvan

Speakers Analyze Situation and Outline Future Plans—Need of Co-operation Is Keynote of Meeting

PAST progress and future plans largely featured the address of Dr. C. H. Herty at the annual meeting of the Synthetic Organic Chemical Manufacturers held March 7 at the Hotel Pennsylvania, New York City.

F. P. Garvan also spoke, bringing out many points of interest both to manufacturers and to the public. He emphasized the absolute necessity of co-operation if the American dye industry is to progress. Education of the people to the menace of foreign monopoly was also stressed as an essential to a healthy state of the American industry.

Dr. Herty's remarks, broad in scope, threw much light on the situation and upon the activities of the association, which he outlined from the trials and triumphs of the past year to the plans for the coming year. Dr. Herty opened his remarks by saying:

"The constitutional year just ending may well be designated one of the most remarkable periods through which any branch of industry has passed. Faced at the outset with a Congressional investigation, avowedly proposed with hostile intent; engaged for months in a struggle for legislation assuredly protective against a vicious foreign competition; shaken for a while to its very roots by an unexpected governmental attack upon the governmental authorized holding of important patents; bearing throughout this period the brunt of a general industrial depression; surely these have been times to try men's souls. And yet at the close of the year we find the clouds dispersed, our industry enjoying a far larger measure of sympathetic public understanding, constantly increasing cordial relations between producers and consumers, ample contentment with the quality and price of our products and consequent placing of orders which insure prosperous times ahead."

Public Support Gaining

The problem of molding intelligent public opinion, of showing the public the real nature and significance of the dyestuff industry, is difficult but not impossible. Dr. Herty cited the public support which is being given to the industry by the medical profession, which is coming to realize the importance of the industry to the public health of the nation. The work of the Chemical Foundation in regard to fostering public opinion of the right sort by showing the vital importance of chemistry to every line of human endeavor was highly praised.

In commenting upon relations with Germany, he spoke of the protest offered by the association against the revival of the patent convention of 1909. The matter is still unsettled and is likely to become an issue of decided importance. Co-operation with the U. S. Army in the study of war essentials and the advance of public welfare through doing away with stream and air polution also were discussed.

Commercial development, especially through the assistance of information furnished by government bureaus, was urged as an indication of progress.

President Herty said in conclusion:

Portentous Changes Imminent

"As we begin this second year of our association's existence, portentous changes seem imminent in world conditions of the chemical industry. No one can predict what may result from the occupation of the Ruhr and from the dislocation of normal business activity in all parts of the occupied area in Germany. Official statements of the Department of Commerce make clear that already prompt forwarding of exports is being seriously hampered; doubtless the embargo on shipments from the Ruhr to others parts of Germany will soon make its demoralizing influence felt in a shortage of crudes and intermediates.

"The nation which purposely inflated its currency, partly for the sake of regaining control in foreign markets, is now paying the price of such debauchery. Whatever the outcome, the fact is once again brought home closely that as to the products of our industry America must make itself forever independent. Therefore upon us is laid afresh the responsibility of seeing that this independence is gained.

"How can it be done? The industry must seriously set about the task of expanding our lines of products as quickly as possible, so that no consumer may feel the need of looking beyond our shores to cover fully his every need. To do this the research chemist must be given fullest opportunity to lead the way, the best of engineering talent must be employed to translate effectively the results of laboratory research into terms of highest efficiency in plant operations, and financing must be sound.

"It is no inviting field into which novices may rush, but the experience gained during the past 5 years must be utilized to the maximum. The daily evidences of how brilliantly that experience has been achieved gives full conviction that the task will be fully met. It is an inspiring thought that over and above the normal satisfaction arising from work well done and reasonable profits justly earned there stands the loftier feeling that through the success of our efforts we are contributing directly to the security of the nation, the health of our people and the economic independence of our country."

A sidelight showing the consumer's growing interest in American chemical industry appears in a letter written by John P. Wood, president of the American Woolen Association, to Dr. C. H. Herty, in which he writes:

"It would have given me a great deal of pleasure, for myself and on behalf of those whom I represent, to renew the assurance so often given in the past of our very sincere and earnest desire for the prosperity and for the most complete and successful development of the American dye and chemical industries."

Officers of the Association

The board of governors of the Synthetic Organic Chemical Manufacturers Association of the United States elected for the coming year are: President, Charles H. Herty; treasurer, F. P. Summers, Noil Chemical & Color Works, New York City.

Dyestuffs Section—F. E. Signer, vice-president Butterworth-Judson Corporation, New York City; August Merz, Heller & Merz Co., Newark, N. J.; C. N. Turner, Newport Chemical Works, Passaic, N. J.; F. P. Summers, Noil Chemical & Color Works, New York City; George H. Whaley, John Campbell & Co., New York City.

Crudes and Intermediates Section—F. W. Pickard, vice-president E. I. du Pont de Nemours & Co., Wilmington, Del.; S. W. Wilder, Merrimac Chemical Co., Boston, Mass.; R. N. Wallach, Grasselli Chemical Co., New York City; William S. Weeks, Calco Chemical Co., Bound Brook, N. J.

Fine Organic & Medicinal Chemicals Section—A. S. Burdick, vice-president Abbott Laboratories, Chicago, Ill.; Herman Seydel, Seydel Chemical Co., New York City; G. F. Richmond, Antoine Chiris Co., New York City.

Boll Weevil Campaign Elects Officers

Organized activity is well under way at the headquarters of the National Campaign for Boll Weevil Control. Dr. Miller Reese Hutchison, president and general manager, whose position in regard to the American Cotton Association is clear since he has definitely announced his severance of all connection with the same, is drawing men of prominence into the new organization. These appointments include Frank S. Bragg, vice-president Union & Planters' Bank & Trust Co., Memphis, Tenn., treasurer; general counsel, John D. Martin, Memphis, Tenn.; secretary, A. B. Meserlin, New York; assistant treasurer, Floyd Swift, Union & Planters' Bank & Trust Co., Memphis, Tenn.; assistant secretary, M. V. Birney, New York.

Australian Sulphur Duty Favors Britain

The Australian Government has decided to allow the importation of sulphur for use in the manufacture of superphosphates free of duty from Great Britain. Sulphur from other countries will be subject to a duty of 10 per cent.

A.E.S.C. to Standardize Scientific Symbols

Conference Reveals Strong Sentiment for Unified Technical Abbreviations—Foreign Help Sought

A recent conference held in New York City under the auspices of the American Engineering Standards Committee revealed a sentiment among engineers, scientists, government officials, business paper editors and industrial executives in favor of the unification of technical and scientific abbreviations and symbols.

It was agreed that the standardization of abbreviations and symbols would result in decided mental economies. The present situation with respect to the use of abbreviations and symbols in engineering, scientific and other technical fields is comparable to a language which has degenerated into a multiplicity of dialects, each of which has to be translated for the users of the others. Abbreviations and symbols constitute an ever-growing and important part of the language of engineers, scientists, industrial editors and other technical men. The use of one symbol or abbreviation for several different terms and the use of several different symbols or abbreviations for one meaning are, however, at present causing a great deal of confusion, misunderstanding and often serious errors.

Foreigners to Co-operate

The conference was called upon requests from the American Institute of Electrical Engineers, the American Society of Mechanical Engineers and the Association of Edison Illuminating Companies, to consider abbreviations and symbols, but after some discussion of the subject it was thought desirable to include as a part of the project the graphical symbols which are used in engineering drawings, diagrams and the like for representing instruments and apparatus and components of them.

It was agreed that the co-operation of foreign standardizing bodies should be sought in the development of the work. The importance of international uniformity in symbols is great on account of the international character of much engineering and scientific work, and the importance of reference books and periodicals in foreign languages.

The work will go forward under a committee organization developed in accordance with the rules and procedure of the A.E.S.C.

Congress Starts Metal Inquiry

The gold and silver industries are to be investigated during the Congressional recess. Miners, smelters and railway executives are to be called to Washington to confer with the commission conducting the inquiry. The object of the investigation is to locate the causes of the depressed condition of the industry, including the production, marketing, transportation, sale and uses of gold and silver. Also the effect of decreased production upon commerce, industry, exchange and prices will be looked into.

Tariff Board Splits on Flexible Plan

The Tariff Commission has split on the question of the general policy to be followed in administering the elastic provisions of the new tariff law, and the differences of opinion have been put before President Harding for decision. Upon his return from Florida the President is expected to determine the general line of activity to be carried on by the commission.

Meanwhile the commission has decided to proceed with the investigation of the cost of production of twenty-five or thirty commodities, which have been made the subject of complaints, calling for an equalization of costs through the elevation or reduction of customs duties. The list of these commodities will be announced shortly.

Plans for Procedure

Field investigations into the costs of production of the chosen commodities, which include chemicals and textiles, will be made and public hearings are to be held. It is stated by the commission that it will be 2 months or so before sufficient information has been gathered to warrant commencement of the hearings.

The Tariff Commission is enlarging its staff for this work and announces appointment of a chief and an assistant economist. Dr. John R. Turner, dean of the Washington Square College of New York University, has been appointed chief economist of the Tariff Commission.

Dr. A. L. Faubell, also of the Washington Square College, was named as assistant chief economist. Their university duties, it is said, will require their attention until May 15, after which date they will assume their new posts with the Tariff Commission.

Reforestation for Paper Pulp Industries

Paper Makers' Interest in Timber Growth Increases—Many Firms to Aid Work

As a result of the increasing scarcity of natural forest acreage available for exploitation by paper pulp interests, the manufacturers in this line are more and more turning their attention to reforestation of cut-over lands.

In this connection, the Chateaugay Pulp & Paper Co., Chateaugay, N. Y., has recently arranged with the New York State Department of Conservation for the planting of 150,000 Norway spruce trees for artificial reforestation for paper pulp supply. The Bogalusa Paper Co., Bogalusa, La., has transferred to the state for technical forest management a total of 53,000 acres of land. It is proposed to co-operate with the state for the scientific growth of timber to insure permanent raw material supply for the local mills. The Mead Pulp & Paper Co., Dayton, Ohio, has been conducting a series of experiments in the Ohio Valley district for reforestation with woods adaptable to pulp production, and plans to develop a large mileage for this purpose.

In Maine, three paper companies are now giving active attention to future raw material source, utilizing spruce as well as pine. The Eastern Manufacturing Co., Bangor, is giving over land for this development, as are the Orono Pulp & Paper Co., Orono, and the Pejepscot Paper Co., Brunswick.

The Canadian Department of Forestry is working with the Price Brothers Co., Quebec, for the reforestation of land for mills of this organization. So far, 900 square miles has been turned over to the department for a pulp wood forest.

Tariff Commission Studies Foreign Discrimination

Unfair Treatment of U. S. Products Causes Complaints—Cottonseed Oil a Case in Point

THE retaliatory provisions of the new tariff bill may be invoked if the present investigations of the Tariff Commission confirm the numerous complaints of discrimination against American commodities by foreign countries.

The commission expects to complete its study of these complaints shortly. If the State Department agrees to the procedure initial steps in retaliation will then be taken. This will be difficult, according to the commission, because much of the discrimination is under the cloak of most favored nation clauses of commercial treaties.

Cottonseed Oil Case

Italian imports of American cottonseed oil are an example. Italy has a most favored nation clause in its commercial treaty with the United States, but at the same time imposes a higher duty upon cottonseed oil than upon other oils usable for similar purposes. While the duty so imposed would apply equally to other nations, the fact remains that nearly all of the cottonseed oil originates in this country and the high customs rate on the commodity in comparison with other oils is considered as in effect a discrimination.

Other countries against which complaints of discrimination have been brought are Canada and Finland. Canada has a preferential tariff agreement with Great Britain and in addition agreements with France and Japan which are complained of as operating in discrimination of this country's products. American automobile manufacturers complain that French cars enjoy a 30 per cent advantage compared with their product on entering Finland.

Iota Sigma Pi of Yale Invites Women Chemists

The Yale Chapter of Iota Sigma Pi, national honorary society for women in chemistry, announces that it extends a cordial invitation to all women in any branch of chemistry to attend the meeting of the American Chemical Society at New Haven, April 2 to 7. A special program is being arranged by the young ladies in the departments of chemistry and physiological chemistry in the Graduate School of Yale, and they also expect to take care of the entertainment of visiting women chemists.

Iota Sigma Pi is represented by active chapters in a number of the leading universities of the country and is proving a very valuable means of encouraging interest in the subject, especially in graduate work. The requirements for membership are a completion of forty year-hours of chemistry with a grade of B, but the major portion of the membership is composed of graduate students and women actively engaged in chemistry. Mme. Curie is one of the honorary members of the organization.

Announcement will be made later of the special features of the program concerning this organization and the name of the speaker, a noted woman chemist, who will deliver a special address some time during the A.C.S. meeting.

Hafnium Samples Coming to America

The first definite information upon the discovery of hafnium is contained in a letter from Dr. G. Hevesy of Copenhagen, the discoverer, to Dr. George F. Kunz, president of the New York Mineralogical Club. Dr. Hevesy wrote as follows:

"We investigated a great number of zirconium minerals from all parts of the world, and we found in all these specimens 5 to 10 per cent of hafnium. Taking into account Clark's estimate of the zirconium content of the earthcrust (0.018 per cent), our estimate of the hafnium content of the earthcrust, one to one hundred thousand, is certainly not too high. All commercial preparations of pure zirconium contain 1 to 5 per cent of hafnium."

Dr. Kunz's Opinion

Dr. Kunz, in commenting upon the discovery, said:

"We are awaiting with the greatest interest more detailed information regarding the special properties of this element. It is too early to say what commercial value it will have or what use will be made of it, but the discovery of new fundamental elements is so rare that this in itself is noteworthy. It may even exist in greater quantities than these two eminent scientists believe."

Zirconium, from which the element was extracted, is in free commercial distribution, and is used in the manufacture of refractive substances.

Match Manufacturers Form Merger

Corporation Perfected to Meet Competition of Powerful Companies Will Be Third Largest of Its Kind

A merger of nine of the small match companies of the United States has been formed under the name of the Federal Match Corporation in order to obtain collectively the strength needed to compete with the larger companies in the field.

The consolidation of these companies represents about 20 per cent of the business of the country, and will result in economies through centralized management, purchasing, reduced freight costs and sales expense.

Companies Forming Merger

The companies forming the Federal Match Corporation are: Fred Fear, Bloomsburg, Pa.; the Pennsylvania Match Co., Bellefonte, Pa.; Union Match Co., Duluth, Minn.; Reliable Match Co., Ashland, Ohio; Indiana Match Co., Crawfordsville, Ind.; National Match Co., Joliet, Ill.; Wheeling Match Co., Wheeling, W. Va.; Cleveland Match Co., Cleveland, Ohio, and Minnesota Match Co., Duluth, Minn.

The total net assets of the companies are about $5,000,000, and the authorized capital stock of the newly formed Delaware corporation is $6,000,000. Preferred stock, of which about $5,000,000 is to cover the net assets of the corporation, will be issued. It is not planned to offer any of the stock issued to the public. Heavy timber purchases and operation of block plants are features in the plan to meet the competition of large companies already in the field.

Mines Bureau Expands

To provide for the additional duties which have been entrusted to the Bureau of Mines by the Congress and by the Secretary of the Interior, Director Bain has announced an organization change creating a leasing branch of the bureau. The new branch is to be under the immediate supervision of A. W. Ambrose, the assistant director, who also will act as consulting engineer to all branches of the bureau on matters relating to petroleum and natural gas.

The name of the investigations branch of the bureau is changed to research branch. Dorsey A. Lyon, the chief metallurgist of the bureau, has been placed in charge of the research branch with the title of assistant director. As assistant director, he will continue to perform the duties of supervisor of the bureau's experiment stations.

F. J. Bailey, as assistant to the director, will be in charge of the operations branch of the bureau. T. T. Read has been appointed supervising mining engineer. C. E. Julihn will succeed him as chief of the information service. Francis Winslow will succeed Mr. Julihn as chief mining engineer of the War Minerals Relief Commission.

Mammoth Oil Well Found in Venezuela

The recent bringing in of one of the largest oil wells the world has ever known, with a daily production of more than 100,000 bbl., has greatly stimulated interest in oil development in Venezuela, where a number of American and British companies are in lively competition with one another to open up promising fields in which they have secured concessions.

Many of the concessions which these companies have obtained date back to the days of former President Castro, while a few run back into the last century. The present Venezuelan Government, however, is respecting all these concessions, no matter when acquired, and concerns which are operating under them are doing so without any trouble, according to advices received here.

Among the British companies operating are the Venezuelan Oil Concession, the Colon Development Co., the British Controlled Oil Fields, Inc., the North Venezuelan Co., and the Caribbean Petroleum Co.

Air Reduction Enters the Cyanide Field

It has been recently announced that the Air Reduction Co., Inc., of New York has joined with Los Angeles capitalists in the formation of a company to be known as the California Cyanide Co. to engage in the manufacture of liquid hydrocyanic, sodium cyanide and kindred products. The Air Reduction Co. itself is one of the two largest producers of oxygen, nitrogen, acetylene and oxyacetylene and welding apparatus in the United States. Among its directors are P. A. Rockefeller, Robert W. Goelet, Samuel F. Pryor, Guy Cary, Frederick B. Adams, John McHugh and Frederick W. Allen, of Lee, Higginson & Co.

A Million Dollar Concern

The interests in southern California which have joined with the Air Reduction Co., Inc., are headed by F. W. Braun, of Los Angeles, long known as a pioneer in the application and use of liquid hydrocyanic in citrus fruit tree fumigation, as well as in the use and application of sodium cyanide in mining operations. Mr. Braun has accepted the presidency of the California Cyanide Co. Steps have been taken by the two groups involved to raise more than a million dollars for working capital for the new company, and work on a new plant will be started immediately.

A ten-acre tract on Boyle Avenue may be selected as the site for the plant. Associated with Mr. Braun in executive and directorate capacities in the new corporation are John Pike, vice-president; J. D. Neuls, in charge of field work; R. W. Poindexter, in charge of laboratory and research work; H. W. O'Melveny, S. F. Pryor, L. F. Loree and C. C. Adams, directors.

Commerce Department to Amplify Coal-Tar Reports

While the February report of the Department of Commerce giving in detail imports of coal-tar dyes at New York during that month was an improvement over the first report of this character, that for January, in that it showed the quantity proportion of each shipment by country of origin, it has been announced that an effort will be made to amplify these statistics further hereafter. The future amplification will not be in the direction of further information regarding dye imports, it is said, but will be an effort to add statistics of other coal-tar products.

The importance of giving information of imports of coal-tar intermediates, as well as finished products, has been recognized and it is probable that the first extension of the service will be inclusion of intermediates in the monthly reports. Some of the intermediates are imported in a condition so nearly finished that without information of the volume of such receipts domestic producers do not have the full picture. It is known, for instance, that considerable indoxyl is coming into the country, about 95 per cent completed for indigo and requiring only a little air until finished.

Later, if the finances of the statistical department will stand the strain, it is hoped by the chemical division of the Department of Commerce to add coal-tar chemicals other than dyes and also synthetic organic chemicals from other than a coal-tar base.

Navy Department to Have Helium Plant

The Navy Department has requested the Bureau of Mines to design and install a plant at the Lakehurst flying field for the repurification of helium. The plant is to have a capacity of 10,000 cu.ft. of helium per hour. It will combine high-pressure purification and charcoal purification at low temperatures. The high-pressure cycle will step up the helium from 85 to 94 per cent. The charcoal will boost it from that point to practically 100 per cent. The plant will be completed this fall. The design of the new plant is being made by Dr. R. B. Moore, the bureau's chief chemist.

Naval Stores Export Corporation Requests Charter

Rosin and turpentine of all kinds will be exported by the Naval Stores Export Corporation of New Orleans if the papers which have been filed with the Federal Trade Commission meet with approval. The corporation would include in its organization about twenty firms doing business at present in Florida, Louisiana and Alabama. At the present time the United States produces about 75 per cent of the world's total supply of naval stores, of which more than half is exported. In 1921 the value of our exports of these commodities was over $11,000,000.

Limits Alsace Potash Exportation

French Bill Leases Mines for 75 Years and Outlines Plan of Distribution

No potash in the future will be exported from Alsace until French requirements have been met. This is in accordance with a bill recently passed by the Chamber of Deputies, which acts as a pendant to that recently voted ratifying the agreement with the Badische Anilin and Soda Fabrik, whereby the Alsace mines are to be leased for 75 years. Both bills provide for the production of fertilizers essential to agriculture by companies organized on national lines and working on the co-operative principle. It is estimated that the Alsace mines should produce a quarter million tons of potash annually.

Bureaus Co-operate to Study Corrosion

To avoid any duplication of work, a co-operative arrangement has been completed between the Bureau of Mines and the Bureau of Standards for the handling of studies being made of corrosion. The work is confined mainly to the corrosion problem as it affects metals and alloys exposed to mine waters.

Despite the fact that corrosion has been one of the most active deteriorating agents throughout the entire history of the use of metals, the factors underlying the phenomena of corrosion are little understood. It is with the idea of illuminating this subject that the Bureau of Mines and the Bureau of Standards are contemplating more active work on it. Considerable progress already has been made, particularly in the devising of methods whereby corrosion can be brought about quickly in the laboratory to an extent which would require years of exposure under ordinary conditions.

Professor Paterno Honored

The Italian Association of General and Applied Chemistry has appointed a committee under the presidency of P. Ginori Conti, to arrange a celebration in honor of the seventy-fifth anniversary of Professor and Senator E. Paterno.

As a permanent memorial of the occasion, the committee has decided to establish a memorial fund for the "Paterno medal," which will be conferred annually upon the author of the most important contribution to chemistry, regardless of his nationality.

In order that the endowment of this medal may be given an international character, the committee welcomes contributions from the chemists of the world in support of the medal. Subscriptions from American chemists may be forwarded to the Division of Chemistry and Chemical Technology of the National Research Council, Washington, D. C., for transmission to the Italian committee.

Fertilizer Monopoly Seen by Trade Commission

The mixed fertilizer business in the United States is increasingly passing into the control of seven large companies and their subsidiaries, the Federal Trade Commission reported to the Senate March 3 in response to the Norris resolution for information. The report indicated a tendency toward price control through uniform contracts making dealers virtually agents.

Co-operative buying by farmers was described as the most important factor in lowering the price. The American Agricultural Chemical Co. dominates the fertilizer situation in the North and the Virginia-Carolina Chemical Co. in the South, according to the report. Their combined output is about one-third of the country's total. These two companies, with the International Agricultural Corporation, the F. S. Royster Guana Co., the Armour Fertilizer Works, Swift & Co. and the Baugh companies and subsidiaries, produced 65 per cent of the commercial fertilizer in 1921, compared with 58 per cent in 1916.

Oil Leases Denied to Aliens

The decision of the Interior Department holding that companies in which aliens have a controlling interest cannot obtain leases of American oil lands was reaffirmed in a decision announced March 6 in the case of the Roxana Petroleum Corporation. Approval of the decision was said to be the last official act of Secretary Fall before he retired from office.

The policy of the government regarding alien control of domestic oil supplies was announced in 1922, but had never been tested until the Roxana company appealed from the department regulation which prevented it from carrying out operations designed to take over extensive lands held by the Creek tribe in Oklahoma. In the hearing granted the company by the Interior Department, it was developed that although it was a domestic corporation, more than 65 per cent of its stock was owned by Dutch and British interests.

Potters Plan Convention

The annual meeting of the United States Potters' Association, postponed from December last, will be held at the Hotel Astor, New York, April 10-12. A feature of the meeting will be a report of the research committee of the organization, of which A. V. Bleininger, Homer Laughlin China Co., Newell, W. Va., is chairman. It is expected that President Frank P. Judge, National China Co., Salineville, Ohio, will be re-elected to this office. Charles F. Goodwin will be re-elected secretary-treasurer and historian. At the last annual meeting at Washington, D. C., fifty-eight companies in the general ware line were registered, representing 633 kilns, with three companies in the sanitary ware branch of the industry, representing 87 kilns.

Reparation Dyes Resold in U. S. by Italy

Of the dyestuffs imported into the United States in February, 26 per cent were reparation dyes, sold on the American market by Italians, according to statistics recently made public by the Department of Commerce. According to this report every pound of dyes brought in from Italy and much of those from France were made in Germany.

Officials of the Tariff Commission say these dyes were granted to the Italian Government as reparations and resold to American importers. It is the well-established policy of Italy to take reparations in any goods whatever and convert them into gold.

Helium to Fill Dirigible

Helium will be used for the inflation of the balloon in the navy's first rigid dirigible, ZR-1, which is being built at Lakehurst, N. J. The dirigible will require 2,000,000 ft. of the gas. Although the United States possesses helium in comparatively large quantities, this plan will draw heavily upon the supply. Nevertheless, helium is to be used regardless of cost, in order to reduce the explosion risk to a minimum.

The recent navy appropriation bill increased the amount allowed for the production of helium, permitting the continuous operation of the plant at Fort Worth. It was planned to produce 12,000,000 cu.ft. during the next fiscal year. At that time the combined helium stocks of the army and navy were 1,822,000 cu.ft.

Bureau of Mines Reviews Rain-Making Scheme

Method of Precipitating Rain and Dissipating Fog Described by Dr. Moore, the Bureau's Chemist

Dr. R. B. Moore, chief chemist of the Bureau of Mines, has authorized the following statement in connection with the work of L. F. Warren and Dr. W. D. Bancroft in connection with the dissipation of clouds and the precipitation of rain with electrified sand:

About 2 years ago Mr. Warren came to my office several times and talked over the plans of himself and Dr. Bancroft in the dissipation of clouds and fog and the possible precipitation of rain from such clouds. He explained his ideas and I encouraged him, because the scheme at least showed possibilities of success, although its value could be determined only by actual trial I am very glad to know of the results of the recent tests and that my judgment was not entirely wrong.

Use of a Dielectric

The method consists in charging a dielectric, such as fine sand, with a static charge, and then sprinkling this sand over the top of a cloud by means of an airplane As everyone knows, clouds consist of minute particles of water, a large proportion of which are charged. All the particles in the same cloud are charged either pos'tively or negatively, and therefore as they carry the same sign, they repel one another when they come into too close contact. This militates against the coalescence of the particles to a size that allows them to fall through the atmosphere in the form of rain. Anything which will dissipate the charge on the particles will help coalescence, and therefore will assist in precipitation.

There was no doubt in my mind 2 years ago that the scheme of Mr. Warren would have at least partial success. The whole question that had to be proven, however, was to what extent precipitation in the upper part of the cloud would have on the rest of the cloud below. In other words, would the effect be cumulative so that the whole cloud could be dissipated? This point could be cleared up only by trial.

The Apparatus Used

I have had no opportunity for personal observation in connection with tests already made, but I have read the affidavits of the observers and also of the army fliers who took part in the tests. From these affidavits it appears that a single airplane has been able to dissipate a cloud a mile or two long and over 1,000 ft. deep in a few minutes by using about 100 lb of charged sand

The apparatus which Mr. Warren uses for charging the sand is not by any means perfected, and he is able to get only 12,000 or 14,000 volts on the particles. In addition, it has not been possible so far to charge more than a small proport'on of the sand grains I see no reason why the voltage cannot be increased with improved apparatus up to 30,000 volts or even more, and also why the percentage of charged grains cannot be greatly increased Under such conditions a still greater effect should be obtained with a given weight of sand

Possible Utility

The work is still in its initial stages and it is difficult to state definitely its possibilities in the future. No trials have yet been made on fog, as the conditions have not yet been favorable for an airplane to go up in a fog and make the tests

Fogs are a combination of mists or "clouds" in contact with the earth, mixed with more or less smoke Whether it will be more difficult or easier to get rid of such fogs than has been the case with clouds high up in the air is yet to be determined, but the methods certainly show great promise and justify a complete investigation by a satisfactory series of trials with improved apparatus If such fogs can be dissipated, the results would be of tremendous value to cities such as London and San Francisco, besides being of great use to the Air Service in connection with its flying fields

Refractories Investigation Begins

The Bureau of Mines laboratory car "Holmes" is now at the plant of the American Refractories Co. in Baltimore, where initiatory work on the co-operative investigation between the Refractories Manufacturers Association and the bureau has begun. The objects of this investigation are to decrease fuel consumption in burning refractories, to shorten the time of burning, and to improve the quality of the product.

Paint Men Not Indicted

The United States District Attorney in Philadelphia has announced that the findings of the federal grand jury will lead to no indictments against the Paint Manufacturers Association of the United States or any of its members. Charges of price fixing, restraints of trade and other alleged violations of the Sherman anti-trust law were investigated.

California Chemists Are Active

On March 2, Professor Blasdale of the University of California addressed the California Section of the American Chemical Society of San Francisco on "Equilibria in Solutions Containing Carbonates and Chlorides of Sodium and Potassium." G. H. West also read a paper on "The Manufacture and Purification of Oil Gas."

Discriminating Law Hits Bauxite Producers

The Legislature of Arkansas has passed a bill that proposes a production tax of 25c. per ton on bauxite produced in the state. This amounts to 2½ per cent, based on the average price of bauxite ($10) in 1921 and 1922; 3.9 per cent, based on the average selling price ($6.38) of domestic bauxite in 1921, and 5.2 per cent, based on the average selling price of the domestic product before the war. That the new measure is discriminatory is indicated by the fact that coal is taxed but 1c. per ton and timber bears a burden of only 7c. per 1,000 ft.

The effect of the measure, if signed by the Governor, may well be to curtail production of bauxite in the state, which contributes 90 per cent of the domestic supply. Such curtailment would stimulate foreign competition and prove highly detrimental to the exploitation of domestic deposits.

Obituary

Frederick Bennett Randall, secretary and treasurer of the Mann Linseed Oil Co., Buffalo, N. Y., with which he had been for many years, died recently.

In the sudden death on March 1 of Prof. Harry Harkness Stoek, the coal industry lost one of its foremost investigators and the chemical and metallurgical industries lost a friend whose advice and counsel have been reflected in many fundamental studies of our fuel problems.

Professor Stoek had been professor of mining engineering and head of that department in the University of Illinois since 1909. After being graduated from Lehigh University in 1887 and completing a year of post-graduate work in mining and metallurgy at the same institution, he spent a number of years as a mining engineer in the coal field

PROF. H. H. STOEK

of Pennsylvania. Returning to Lehigh in 1900, he was instructor in mining, metallurgy and geology. It was in this capacity he became familiar with the iron and zinc industries of eastern Pennsylvania, as well as the anthracite coal mines of that section.

For 9 years prior to September, 1909, Dr. Stoek was managing editor of *Mines and Minerals*. Later on in connection with other editorial work he revised and edited the mining publications of the International Correspondence School, "Coal and Metal Miners' Pocketbook," Fulton's "Coke," Lake's "Prospecting for Gold and Silver" and "Examination Questions for Certificates of Competency in Mining" and prepared for the United States Geological Survey a chapter on "Anthracite" included in the Twenty-second Annual Report of the Survey. His own publications include several well-known volumes on coal mining, mining education and the problems of coal storage. It was toward the last-named problems that his more recent efforts have been directed. He had just been appointed by the American Engineering Council to serve on a committee of engineers to make a detailed study of storage for commercial and industrial purposes. During the Christmas holidays he aided in the preparation of the preliminary report on coal storage for the Federal Fact-Finding Coal Commission, of which he was a member.

Professor Stoek was a widower at the time of his death. His wife was Miss Miriam Ricketts, of Wilkes-Barre, Pa., to whom he was married Dec. 20, 1894. He is survived by one daughter, Miss Leigh Stoek, of Urbana, Ill. He was just past 57 years of age, having been born in Washington, D. C., Jan. 16, 1866.

IRA A. SHOFF, chief engineer, West Penn Steel Co., Brackenridge, Pa., since its organization in 1908, died on February 28.

Personal

LEASON H. ADAMS, of the Geophysical Laboratory, spoke before the Chemical Society of Washington, March 8, on "Reactions and Properties of Substances at High Pressures."

PERRY H. BASCOM and CLEO HAROLD KIDWELL, formerly with Raymond F. Bacon, consulting chemical engineer at 50 East 41st St., New York, have organized the firm of Kidwell & Bascom, Inc., with offices and laboratory at 27 Thames St., New York. The new firm will do consulting chemical engineering work and developmental research. Raymond F. Bacon is a director of the firm, and Elizabeth N. Kidwell is bacteriologist.

Dr. CHARLES B. BAZZONI, professor of experimental physics, University of Pennsylvania, spoke before the Franklin Institute, March 8, on "Ionization and Resonance Phenomena."

Dr. HENRY R. CURME, formerly a non-resident Fellow of the Mellon Institute of industrial Research, connected with the staff of the Carbide & Carbon Chemicals Corporation, Clendenin, W. Va., has accepted a position with Savell, Sayre & Co., Inc., Niagara Falls, N. Y.

FRANCIS B. DAVIS, JR., connected with E. I. du Pont de Nemours & Co., Wilmington, Del., in an engineering capacity in different departments for a number of years, has been appointed assistant general manager of the pyralin department, and will assume his new duties about March 15. During the war period he was identified with the black powder department as division superintendent, and later was successively assistant engineer, resident engineer and assistant manager at the guncotton plant at Hopewell, Va. He acted as assistant manager in connection with the construction of the Old Hickory guncotton and smokeless powder plant for the United States Government. At the close of the war he was appointed vice-president and general manager of the du Pont Chemical Co.

Dr. HARRY ESSEX, professor of physical chemistry at Syracuse University, addressed the Syracuse Section of the American Chemical Society on March 9. His subject was "Isotopes."

General AMOS A. FRIES gave an interesting address at the February meeting of the Delaware Section of the American Chemical Society, Wilmington, on "Chemical Warfare Materials—What They Are, How Produced and Their Peace-Time Uses."

Dr. WILLIAM D. HARKINS, professor of physical chemistry at Chicago University, gave a course of three technical lectures, March 7, 8 and 9, at Carnegie Institute of Technology, Pittsburgh, on "Isotopes and the Building and Disintegration of Atoms."

CHARLES H. MACDOWELL, president of the Armour Fertilizer Works, sailed for Europe recently and expects to return about the middle of April.

Dr. ROYAL A. MEEKER has been appointed Commissioner of Labor and Industry of the State of Pennsylvania by Governor Pinchot, to succeed Dr. Clifford B. Connelley. Dr. Meeker has been chief of the scientific division, international labor office, of the League of Nations since August, 1920. Previously, from 1913 to 1920, he served as United States Commissioner of Labor Statistics by appointment of President Wilson. Since 1916 he has been secretary and treasurer of the International Association of Industrial Accident Boards and Commissioners. Dr. Meeker is a native of Pennsylvania and attended the Iowa State College, Columbia University and the University of Leipzig.

Dr. EDMUND S. MERRIAM of Marietta, Ohio, has resigned as chief chemist for the Safe-Cabinet Co. in order to resume his consulting work in connection with natural gas, casinghead gasoline and carbon black.

F. P. PALMER, a member of the metallurgical staff of the Carpenter Steel Co., Reading, Pa., gave a comprehensive and illuminating address on the subject of "Tool Steel" at the meeting of the Lehigh Valley Chapter of the American Society for Steel Treating, Easton, Pa., March 1.

CHARLES W. PHELLIS, general manager of the Pyroxlin plastics division of E. I. du Pont de Nemours & Co., has resigned to follow personal interests. Mr. Phellis is widely known in the explosive industry of the U. S.

EDGAR S. ROSS, for a number of years engaged in research dealing with production of metallic tantalum and columbium and more recently chemist and metallurgist for McKechnie Bros., Inc., of Philadelphia, has recently accepted an industrial fellowship at the Mellon Institute of Industrial Research, University of Pittsburgh.

C. A. UNDERWOOD, formerly chief chemist of the American Refractories Co., at Joliet, Ill., has been transferred to the sales department at New York as New England representative.

SAMUEL M. VAUCLAIN, president of the Baldwin Locomotive Works, has accepted an invitation from Dr. Thomas S. Baker, president of the Carnegie Institute of Technology, to address the general assembly of students March 14.

Dr. F. C. WEBER, for many years chemist in the Bureau of Chemistry, has resigned to accept a position with the Fleischmann Co., New York City.

JOHN MORRIS WEISS, consulting chemical engineer, of Weiss & Downs, New York, has been selected by the Manufacturing Chemists' Association to serve as its representative on the recently formed sub-committee on benzol poising of the Chemical Section of the National Safety Council.

EDGAR C. WELBORN and WILLIAM CHAPIN HUNTINGTON announce the formation of a partnership to extend the work heretofore carried on under the name of E. C. Welborn. They will continue to make business surveys of industrial enterprises.

The Social Organization of Hungarian Engineers has elected the following officers for the coming year: President, Alexander Strobl, Chemical Engineer; vice-president, Dr. Adalbert Elek, of the Rockefeller Institute; secretary-treasurer, Julian J. Wittal, M.E. (132 Nassau St., New York City). This organization, which comprises in its membership most of the engineers of Hungarian extraction, had a very successful dance-dinner at the Hotel McAlpin, on March 3. The Hungarian Consul-General attended.

Business Profits in 1922

Study of Net Earnings of Important Industrials Offers a Better Index of Business Than Statistics of Production, Consumption, Sales and Prices

THE season of annual reports is with us again and careful students of business are profiting by an opportunity to examine industrial earnings and to compare them with records of past years. While current statistics of production and consumption have offered a fairly precise measure of business activity, there has existed no accurate measure of that more important aspect of business, the amount of net profits. Recently in connection with its "Monthly Review of Credit and Business Condition" the Federal Reserve Bank in New York has tabulated the published statements of net profits for the year 1922 of 122 concerns engaged in production, wholesale and retail trade and public service.

Table I and the accompanying chart show the results of this tabulation by 10 separate groups and in the aggregate for all groups. There is also shown the net operating income of the 193 Class I railroads. In each case the 1919 figures are taken as a basis of 100 per cent.

In every group 1922 net profits were larger than net profits in 1921, but there is large variation between the different groups in the amounts of increase which they show. In 4 of the 10 groups, and in the case of the railroads as well, 1922 net profits were equal to or larger than those of 1919. The aggregate figures for the 10 groups, however, show 1922 figures considerably below those for either 1919 or 1920, reflecting reduced earnings in the steel and other metal industries.

In general, the figures show that 1922 net profits were highest, in relation to 1919, in those industries which deal most directly with the individual consumer. This is true in the cases of food and food products, public utilities, tobacco and clothing. On the other hand it is significant that in the industries of the type of the chemical and metallurgical producers whose production is directed to supplying industry rather than the final consumer, profits in 1922 lagged considerably behind those in 1919 or 1920. The railroads show consistent gains since the year 1920, but even so the percentage of net operating income to property valuation continues to be less than 5½ per cent specified in the law.

A further reflection of changing business conditions is found in the number of concerns which reported deficits. Of the 122 concerns reported, the number showing deficits in each year were as follows:

1919	5
1920	9
1921	34
1922	18

The report points out that in interpreting these data it should be borne in mind that they are simply for a group of concerns, figures for which were available, and are not necessarily typical of all the concerns which deal in the products represented. In a few cases where it has been necessary, fiscal years not corresponding exactly with the calendar years have been used.

Annual reports for a number of prominent companies in the chemical and allied industries will be found on page 520.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	176.76
Last week	176.71
March, 1922	156.00
March, 1921	157.00
March, 1920	252.00
April, 1918 (high)	286.00
April, 1921 (low)	140.00

The prices of all commodities represented by this index number remained at the same level reported last week. A very minor increase in the price of salt cake was responsible for the slight change in this week's index number

TABLE I—INDUSTRIAL EARNINGS IN 1919, 1920, 1921 AND 1922

(Computations of net profits have been before dividends, but after all fixed charges and tax deductions.)

(Thousands of Dollars)

Group	No. of Corporations	1919	1920	1921	1922
Food products	15	51,501	55,255	10,270	54,408
Stores	7	41,447	16,658	*9,938	40,752
Motors	11	53,767	25,757	*23,576	36,408
Miscellaneous metals and oils	8	10,851	7,544	959	2,313

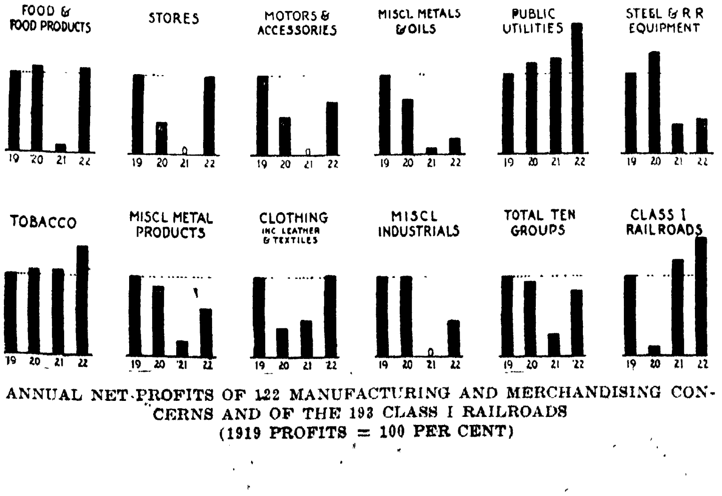
Steel and railroad equipment	14	140,626	176,661	50,466	62,738
Tobacco	9	29,118	30,822	31,007	39,902
Miscellaneous metal products	10	24,996	22,038	5,281	15,228
Clothing (including leather and textiles)	12	28,193	10,312	13,371	28,670
Miscellaneous industrials	12	36,952	36,913	*13,025	17,175
Total 10 groups	122	477,421	449,832	136,328	394,816
Class I RR's	193	516,290	58,152	615,946	776,421

* Deficit



ANNUAL NET PROFITS OF 122 MANUFACTURING AND MERCHANDISING CONCERNS AND OF THE 193 CLASS I RAILROADS
(1919 PROFITS = 100 PER CENT)

Goodrich Earns $3,000,000

The annual report of the B. F. Goodrich Co. for 1922 shows that net sales of the company's products amounted to $93,649,710.08. From this was deducted manufacturing, selling and general administrative expenses of $86,631,163.84 and depreciation and interest provisions of $4,806,060.16. This leaves a net profit (including the miscellaneous income) of $3,047,769.66.

U. S. Gypsum Doubles Earnings

The United States Gypsum Co. and subsidiary companies report for 1922 shows total earnings after expenses incident to operations, etc., of $4,370,770, contrasted with $2,639,552 in 1921, and a surplus after dividends of $2,080,493, against $910,587 in the preceding year. At the end of 1922 the total surplus was $5,615,795, against $3,535,302 on Dec. 31, 1921.

Mathieson Alkali Earnings Show Big Gains in 1922

The Mathieson Alkali Works, Inc., shows its earnings for 1922 to have been $1,633,886 after deducting expenses and other charges. This contrasts with earnings of $366,036 in 1921. The 1922 surplus after dividends was $823,365 as against a deficit of $241,893 in the previous year. The Mathieson company's surplus on Dec. 31, 1922, amounted to $1,949,716, as contrasted with $1,308,432 at the end of 1921.

National Lead Reports Big Earnings

The net earnings of the National Lead Co. for 1922 were $4,927,548 after deducting all expenses, including tax reserves. In 1921 the company's earnings were $3,481,512.

In addition to providing for the regular dividends on the preferred stock, the profits are sufficient to pay $15.59 a share on the outstanding common stock, which totals $20,655,400. Last year the earnings available for the common stock were equivalent to $8.50 per share.

Corn Products Earns $15,453,918

During the year ended Dec. 31, 1922, the Corn Products Refining Co. had a total net income, according to its recent annual report, of $15,453,918, as compared with $10,742,374 in 1921. E. T. Bedford, the president of the company, points out in his letter to the stockholders that the company's surplus was reduced by $20,000,000 as a result of readjustment in the value of operating plants and certain intangible assets such as good will and patent rights.

The consolidated balance sheet on Dec. 31, 1922, shows cash holdings of $1,663,060, as compared with $1,457,805 in 1921.

Better Activity as Prices Advance in New York

Phenol, Acetone, Tin Salts and Barium Carbonate Feature Chemical and Allied Markets

Advances were quite general throughout the list during the past week and the market was fairly active. Manufacturers of acetone announced a new advance due to the increased production costs. Producers of tin salts raised their prices on account of the increase in the metal. One of the outstanding features of the week's trading was the sharp advance in phenol. Scarcity of spot supplies, together with a heavily sold up condition at the works, was directly responsible for the sharp increase. Producers of potassium nitrate announced a reduction of 1c. per lb., on account of the lack of consuming interest. The new level has brought some noticeable trading into producing quarters. Dealers in arsenic report a quiet market, temporarily at least, with quotations fractionally lower for spot and shipment material. Trading in barium carbonate has been more pronounced, with importers somewhat higher on spot. The alkali market continued to improve for export. Caustic soda inquiries were more numerous and several fair-sized sales were reported by the export association. Soda ash continued along steady lines. Oxalic acid, bichromate of potash and soda, copper sulphate, permanganate of potash and caustic potash were very firm throughout the interval, with quotations somewhat higher among first hands.

Principal Price Changes

Acetone—Leading producers announced an advance of 1c. per lb. on carload quantities. Quotations range around 22@22½c. per lb. The demand continues along moderate lines.

Arsenic—Trading has been rather quiet during the week, with resale dealers offering spot goods at 15@15½c. per lb. Shipments were held at 15½c. Consumers have not shown any desire to purchase at present high levels.

Barium Carbonate—This product has shown material strength and leading importers are asking $75 per ton for spot goods. Goods afloat were held around $70 per ton.

Bleaching Powder—Producers reported sales at $2.20 per 100 lb. f.o.b. works for nearby shipments. The market is in a very strong position, with most producers well sold up. Resale lots were quoted around 2½c. per lb.

Caustic Soda—Dealers quoted the market firm at $3.45@$3.50 per 100 lb. f.a.s. There has been an appreciable improvement during the interval, with several large sales reported to South America and Japan. Domestic caustic on spot was quoted at $3.50 per 100 lb. for carload lots and $3.75 for smaller quantities, ex-store.

Caustic Potash—Higher quotations were reported for spot material. Importers quoted 88-92 per cent at 8@8¼c. per lb., with several fair-sized sales at this figure. Higher importing costs, together with the scarcity of spot stocks, were directly the cause of the increased activity.

Phenol—Spot prices have been sharply advanced, due to the extreme scarcity of spot material and the heavily sold up market at the works. Goods on spot were held around 50c. per lb., but actual trading was mostly for small lots. The new level represents an increase of over 15c. per lb. during the past 10 days and also establishes a new high price since January, 1919.

Potassium Nitrate—Manufacturers announced a reduction on all grades. Pure doubled refined granulated is quoted at 6¾c. per lb., in barrels, the powdered at 7¼c. and the large crystals at 7¾c.

Potassium Bichromate—Dealers were somewhat firmer in their views on spot goods, and quotations were fractionally higher. Producers quoted spot material around 10c. per lb. f.o.b.

Potassium Permanganate—Spot offerings were quite scarce, and dealers quoted around 19½c. per lb. Consuming demand has shown an appreciable increase.

Prices Advance Materially in the St. Louis Market

Higher Quotations on Many Items Due to Curtailment of Imports by Ruhr Occupation

St. Louis, March 8, 1923.

Important and striking advances in the drug market since our last letter were the naming of higher schedules on salicylates, bismuth and iodide preparations. In the industrial chemical market there were also a number of important items that were materially advanced, this due principally to developments in the Ruhr situation. Shipments of chemicals from that part of Germany have been materially curtailed, and would not be surprising if they ceased altogether in the near future. The potash salts are the most affected by the curtailment, and spot stocks are hardly obtainable, with prices the highest for many months. Other industrial chemicals and alkalis have also been strengthened considerably, resulting in a heavy buying movement. Transportation facilities are somewhat better, but are still below normal; however, it is the opinion of those directly interested that conditions will greatly improve in the next month or 6 weeks.

Alkalis

The alkali market is firmer now than at any time in the recent past, and while there has been no general increase in schedules, business has been brisk. *Caustic soda* has not changed in price, though a decided improvement in volume of business transacted is reported. *Soda ash*, in sympathy with caustic, is showing improvement.

Schedules have not changed on this item, but prices are firm. *Bicarbonate of soda* has strengthened considerably, 25c. per 100 lb. having been added to the regular schedule recently. Good business on this item is reported. *Sal soda* has been rather quiet recently, though no price reductions have been made. Factors on this item expected this condition to improve.

General and Special Chemicals

Heavy *mineral acids* are going well with a firm market. There have been no startling developments in the *citric acid* market, and while there was a slight increase, the market is still lacking volume. The demand for *oxalic acid* has been very light and the market weak. *Tartaric acid* has not been moving in heavy volume, but the season is approaching when a greater demand should be forthcoming. *Aqua ammonia*, 26 deg., is moving along quiet lines with no change in price. There has been no change in *white arsenic powdered*, and the market is ruling today at 16@16½c. f.o.b. New York. Spot stocks are very scarce and buying is light. Since the advance on bismuth and iodide preparations a very satisfactory business is being transacted. *Glycerine* remains very firm; in fact, is a producers' market. The demand is excellent; prices are holding at 18½c. in drums both for open market and contract quotations. There is a pronounced scarcity of *phenol*, and domestic producers are not in a position to take care of the business. The imported article has advanced and considerably higher prices are expected to prevail in the next few weeks. The spareness of stocks is holding *permanganate of potash* in a strong position and spot goods are hardly obtainable. *Potash carbonate* and *caustic* are much stronger and ruling at higher prices. As a result of the higher market on phenol, *salicylates* have also advanced and stocks in the hands of producers are limited. *Sulphur* is moving in good volume and numerous sales are being reported. Prices are generally firm and declines are not expected. The zinc market is advancing steadily, and *spelter* is quoted today at $7.85 per 100 lb. St. Louis. Excepting during the war period this is the highest price obtained in the spelter market for many years. The *zinc dust* market is also in excellent condition and is advancing in sympathy with the spelter. *Zinc sulphate* is quoted today at 3¼@3⅜c. f.o.b. St. Louis in carload lots and 4c. f.o.b. St. Louis in less than carload lots, with a good volume of business transacted.

Vegetable Oils and Paint Materials

Turpentine is still very firm, the price today being the same as of our previous report, the 5-bbl. price being $1.54 per gal., single barrels $1.58. *Linseed oil* has taken a 3c. advance and is now being quoted at $1.03 per gal. in 5-bbl. lots, $1.13 in single barrels, with the usual differential for boiled over raw oil. *Castor oil* has taken another advance and is now quoted at 15c. lb. in drums. The market is entirely in the hands of producers, with one of the largest factors reporting a shortage of supplies.

Producers in this market report a lively business with firm prices and an increased demand. *Floated barytes* is quoted at $26@$28 in carload lots f.o.b. shipping point, with a $4 differential for single-ton lots. Gilders' *whiting* in carloads is quoted at $18@$20. *Commercial whiting* is quoted at $17 per ton in carloads, with a $3 differential for ton lots applying to both grades.

Iron and Steel Production Reach Record Rates

Market Gaining Strength With Advancing Prices and Heavy Turnover

PITTSBURGH, March 9, 1923.

Production of pig iron and steel has within the last 2 or 3 weeks exceeded the highest rate attained since the armistice, in March, 1920, and is in line, barring accidents, to break the high record of all time, reached in September, 1919. Already the rate in both pig iron and steel is above the greatest production ever attained in a full calendar year.

So far as the market itself goes, there is appearance of greater and greater strength week by week. During January and February the strong features were the advances in finished steel products, with a very heavy turnover in actual tonnage in January. In February one of the outstanding strong points was the refusal of many mills to sell beyond certain dates. In the past week two strong points have been advances in both pig iron and semi-finished steel, with the spread of a delivery premium market in some finished products.

Price Premiums Common

In bars, shapes and plates the basis price or regular market remains at 2.25c., but there are few sellers at this level, and then only for very late delivery. Bars are moving in small lots for early shipment at premiums of from $3 to $5 a ton, while occasionally shapes have gone at such premiums. Plates present the strongest prompt market, as some fairly good-sized tonnages, chiefly for oil tank work, have gone at 2.60c., or $7 a ton premium.

Wire products are difficult to buy at any price, and the market is relatively inactive, with heavy deliveries being made on old contracts. Tubular goods are also very difficult to buy. Consumers and jobbers may be fairly well covered, but their active inquiry would not so indicate. Orders are frequently sent to mills without previous inquiry, and such orders are frequently scaled down in tonnage or rejected entirely. The National Tube Co. has withdrawn as a seller of line pipe or oil country goods, except that it will accept some orders from regular customers, subject to price ruling at date of shipment, and at least one independent has adopted the same policy.

The sheet prices of the Steel Corporation, as recently advanced to 2.65c. for blue annealed, 3.50c. for black, 4.60c. for galvanized and 5c. for automobile sheets, are practically nominal, the company having been sold out for second quarter for some time, while it will hardly open order books for third quarter before about the middle of April. Independents, instead of getting on a uniform basis, as was recently the prospect, are showing a wider range of position. Some have not opened order books even for April shipment, others are quoting for April and others for second quarter, while prices are not uniform. The more common quotations are 2.75c. for blue annealed, 3.60c. for black and 4.75c. for galvanized. Yesterday the Wheeling Steel Corporation and Superior Steel Co. announced advances in their prices to 3.85c. for black and 5c. for galvanized. Automobile sheets alone are uniform in the independent market, mills having opened order books last week for second quarter at 5.35c.

Semi-Finished Steel Irregular

Expectation lately has been that the Steel Corporation would name a $40 price on semi-finished steel for second quarter to the few customers it has retained and that independents would make the same price to their regular customers. In the past week, however, the McKinney Steel Co., Cleveland, has sold some fair-sized tonnages in sheet bars and slabs at $45, Youngstown basis. That figure represents the only market now quotable. A prediction is that the corporation price will be $40 and that independents will split the difference to regular customers, making a price of $42.50.

Is the End in Sight?

While all the superficial market indications are of increasing strength week by week, it is obvious that the market has been stiffening at a dangerous pace and some observers have already grown very suspicious of the future. Clearly the steel market for some time past has not been one that could continue indefinitely. It has not had in it the elements of self-perpetuation. A given batch of purchases has not paved the way for another, but rather has produced price advances and made the mills more reserved about selling additional tonnages. What is occurring is simply a "movement," and thus the question is simply how long it will last. Particular uncertainty exists on account of some mills not having sold far ahead. If mills had all pursued the same policy, as they did before the war, the market could turn quiet at any moment, and production, shipments and consumption would proceed at a high rate for the major part of the year, the industry running on "momentum." That is what it did in 1907, through October. If the market should turn quiet in the near future some mills might in a short time find themselves in need of orders.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 36	- $0 38
Acetone, drums	lb	22	- 23

Soft steel bars	3.19	3.04
Soft steel bar shapes	3.19	3.04
Soft steel bands	3.29	3.19
Plates, ¼ to 1 in. thick	3.29	3.14

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

HOLT—The Central Iron & Coal Co has awarded a general contract to the Ingalls Iron Works, Birmingham, for the erection of a new 1-story plant for the manufacture of cast iron and steel pipe. The estimated cost is reported in excess of $80,000

BIRMINGHAM—The Alabama Hide & Tallow Co, 1608 9th Ave., North, has plans in progress for the rebuilding of its tallow and grease works recently destroyed by fire with loss of about $18,000. Additional equipment will be installed Charles Barber heads the company.

SHEFFIELD—The Alatep Lead Products Co., recently organized, has plans under way for the construction of a new plant for the manufacture of lead battery plates and other lead specialties.

BIRMINGHAM—The Sanitary Chemical Co., recently organized, has plans under consideration for the immediate establishment of a local plant for the manufacture of a line of chemical specialties F T Bell heads the company.

EAST BIRMINGHAM—Following the completion of the first unit of its new pipe manufacturing plant, the McWane Cast Iron Pipe Co, Birmingham, is perfecting plans for the construction of another unit. It is purposed to increase the size of the present foundry, 108x310 ft, to a length of 510 ft. The initial plant will have a rated daily output of 8,000 ft of cast-iron pipe, giving employment to about 150 men J R McWane is president, and James D Sample, vice-president

California

SAN FRANCISCO—The National Lead Co, 485 California St., has awarded a contract to Dyer Brothers, Golden West Iron Works, Kansas St, for the erection of a new 1 story plant at 17th Ave. and East 10th St, Oakland, to cost about $37,000

SAN FRANCISCO—The Jewell Steel & Malleable Co, 1375 Potrero Ave., has awarded a contract to Barrett & Hilp, 918 Harrison St., for the erection of a 1-story addition to its plant to cost about $13,000, exclusive of equipment

Connecticut

SOUTH COVENTRY—The Willimantic Paper Co. is making ready for operations at the plant formerly occupied by the South Coventry Paper Co., recently acquired, and a number of alterations and improvements will be carried out It is expected to commence producton before the close of the month.

Florida

SEBRING—The Town Council is considering the installation of a filtration plant and system at the municipal waterworks, comprising the former plant of the Sebring Light & Water Co., lately acquired for municipal property. Joseph Rawthorne is superintendent

Georgia

ATLANTA—The Atlanta Glass Mfg. Co has acquired a local site and plans for the erection of a new plant for the manufacture of glass bottles and other containers.

WRENS—The McNair-Young Oil Co has tentative plans under consideration for the rebuilding of its local oil plant, partly destroyed by fire, Feb. 23, with loss approximating $50,000, including equipment

TIFTON—The plant of the Tift Silica Brick Co has been acquired by W. W. Pace, Jr., together with a large tract of adjoining property. The new owner will take possession immediately, and plans for general improvements for increased production. The plant will specialize in the manufacture of white silica bricks

FORT VALLEY—The Emergency Products Co., recently organized, is planning for the establishment of a local plant for the manufacture of insect powders and kindred chemical specialties Edward Chambers heads the company.

Indiana

EAST CHICAGO—Following a consummation of the proposed merger of the Youngstown Sheet & Tube Co, Youngstown, O, and the Steel & Tube Co. of America, Chicago, Ill, under the direction of the first-noted organization, plans are being perfected for extensions and improvements in the Steel & Tube Co plants at East Chicago and Indiana Harbor A number of new mills will be built The project is estimated to cost in excess of $5,000,000, with machinery

INDIANAPOLIS—The Chandler & Taylor Co, South Addison St, is planning for the rebuilding of its 1-story foundry, 175x300 ft, destroyed by fire, Feb 24, with loss estimated at $85,000, including equipment The new structure will be approximately the same size The company manufactures steam engine boilers and kindred products. William M Taylor is president

Iowa

MASON CITY—The Cerro Gordo Brick & Gravel Co. is considering plans for the construction of a new brick-manufacturing plant, estimated to cost approximately $40,000 C I Snyder is secretary

Kansas

WICHITA—The Western Glass Co., 531 North Market St., has taken bids on a general contract and will soon make award for the erection of a new 2-story and basement building, 75x130 ft, estimated to cost about $35,000 Edward Forsbloom, Sedgwick Bldg, is architect

Louisiana

NEW IBERIA—The local Chamber of Commerce is considering plans for the establishment of a sugar refinery in or near the city The Parish Farm Bureau, headed by A A Theriot and Louis Pesson, is also interested in the project. It is purposed to select an engineer to prepare plans in the near future.

Maryland

BALTIMORE—Plans are being completed for the erection of a 1-story foundry at the plant of the Bartlett-Hayward Co., Scott and McHenry Sts., manufacturer of machine castings, etc. Parker, Thomas & Rice, Union Trust Bldg., are architects.

HAGERSTOWN—The Elestano Mining Co., 3 Hamilton Row, is planning for the installation of smelting equipment at its new tin ore plant now being established. The company was recently incorporated.

Massachusetts

SPRINGFIELD—The Springfield Gas Light Co. will make extensions and improvements at the purifier building at its local artificial gas plant to cost $23,000. Plans have been completed

BOSTON—The Penn Metal Co, 65 Franklin St., has purchased the local plant and business of the Midvale-Cambria Steel Co., Philadelphia, Pa, covering primarily the steel rod and bar branch of production. The new owner will continue the operation of the mill pending the completion of a new steel rod mill at its own plant, now in course of erection, and later will remove the Midvale works to this location. Expansion in production is planned.

Michigan

MARINE CITY—Sidney C. McLouth is planning for the immediate rebuilding of his foundry, partially destroyed by fire, Feb. 21, with loss estimated at $25,000, including equipment. The plant is devoted primarily to the production of steel castings.

WYANDOTTE—The Michigan Alkali Co., operated by the J. B. Ford Co., has tentative plans under consideration for the erection of a new 2-story plant on Biddle St.

HOLLAND—F. B. Parish has acquired the local foundry of the Holland Engine Co., and will operate the plant as an individual enterprise for the production of iron and steel castings. Extensions and improvements are planned to include the installation of additional equipment.

Missouri

ST. CHARLES—The Crucible Oil & Refining Co., St. Joseph, Mo., has preliminary plans in progress for the construction of a local refining plant, to include a byproducts department for the production of miscellaneous oils The company also operates a works at Wichita, Kan.

ST LOUIS—Tentative plans are being prepared for the construction of a new 1-story foundry at the plant of the Green Car Wheel Mfg Co., 3000 North Broadway. Klipstein & Rathran, Chemical Bldg., are architects

ST LOUIS—The Frictionless Metal Co. has leased property at Cass Ave. and Collins St., comprising a 3-story building, for the establishment of a new plant for the manufacture of babbitt metal The installation of machinery will be commenced at an early date The company is now operating a plant at Richmond, Va., as well as a Canadian branch at Montreal, Que., and it is purposed to remove both of these plants to the new location at a later date. C W Bourne is president.

Montana

GREAT FALLS—The Sunburst Refining Co., recently organized with a capital of $300,000 as a subsidiary of the Sunburst Oil & Gas Co, is perfecting plans for the construction of a new oil-refining plant on local site, with initial capacity of about 4,000 bbl per day. It is estimated to cost close to $150,000 with machinery L. C. Stevenson is president of the parent organization and heads the new company. W. M. Parker is construction engineer in charge.

EAST HELENA—The American Smelting & Refining Co, 120 Broadway, New York, has plans in preparation for the construction of an addition to its local smelting plant, estimated to cost approximately $200,000, including equipment. The extension will be used to handle the increased output from the Hercules and Tamarack mines in the Cœur d'Alene district.

New Jersey

TRENTON—The Trenton Potteries Co., manufacturer of sanitary ware, will immediately commence construction of a 4-story addition to its Equitable Pottery at Lalor and Hancock Sts A 1-story kiln building will also be constructed The new structures will cost about $80,000. S. W Mather & Sons, Greenwood and Canal Sts., have the general building contract.

NEWARK—The Electrified Water Co. has leased the 1-story building at 232 Halsey St. for the establishment of a new plant for the production of water-purifying materials and water-purification systems. The company is operating a number of plants in different parts of the country, and purposes to establish a new works at Los Angeles, Cal. Alfred H. Brundage is president.

NEWARK—The Celluloid Co, 290 Ferry St., has filed plans for the erection of a 1-story addition to its plant at 65-67 Westcott St., estimated to cost approximately $14,000.

BLOOMINGDALE—The Seamless Rubber Co., recently organized, has commenced the installation of machinery in a local building for the establishment of a new plant for the manufacture of hard rubber goods. It is purposed to inaugurate production at an early date.

JERSEY CITY—The Ault & Wiborg Co., 12th St., manufacturer of printing inks, etc., has filed plans for alterations and extensions in its local plant, to cost about $9,000.

TRENTON—George L. Atkins, Langhorne, Pa., has acquired the local foundry of the Reeves Foundry Co., Ward Ave., at a sheriff's sale for a consideration of $72,717. The plant has been closed for a number of months past. The new owner is said to be arranging for the organization of a company to operate the foundry for the production of iron and steel castings.

New York

BUFFALO—The City Council is arranging a bond issue of $2,800,000, of which amount $1,700,000 will be used for the installation of the proposed new filtration plant at the municipal waterworks.

NEW YORK—The Harlem Sugar Co., 2445 8th Ave., has completed plans for the construction of a new 2-story building, 75x100 ft., on the Southern Blvd., near St. Ann's

Ave., estimated to cost about $75,000. Charles Clark, 441 East Tremont Ave., is architect.

BUFFALO—The Federal Concrete Products Co. has made application to the City Council for permission to build a new plant at Kensington and Wyoming Aves., for the manufacture of cement and concrete products, to consist of a main 1- and 2-story building, 80x110 ft., and adjoining structure, 24x67 ft., estimated to cost approximately $30,000, with equipment. Walter E. Jones is president.

North Carolina

BELMONT—The Continental Brick & Tile Co, Chapel Hill, N. C., has commenced the erection of a new plant at Belmont for the manufacture of brick and tile products. Initial production will be devoted to brick with output of about 30,000 per day J G Gullick is president.

Ohio

LISBON—The American Vitrified Products Co is said to be planning for the early rebuilding of the portion of its plant destroyed by fire, March 2, with loss estimated at about $100,000, including equipment.

Oklahoma

SAPULPA The Star Gasoline Co, has commenced the construction of a new gasoline absorption plant in the Boggy farm section, to be equipped for an initial output of 2,500 gal per day

Pennsylvania

LOCK HAVEN—The Harbison-Walker Refractories Co, Farmers' Bank Bldg, Pittsburgh, is said to have preliminary plans under consideration for the construction of a new firebrick and refractory manufacturing plant in the vicinity of Lock Haven

SHARON—The Sharon Brick & Clay Co, recently organized by H. D Beegle, New Galilee, Pa, and associates, has taken over the local plant and business of the Sharon Clay Products Co., secured for a consideration of about $100,000. The new company plans for immediate operations and will make improvements and extensions to develop an output of about 250,000 bricks a week

PHILADELPHIA—The Philadelphia Salt Co, Delaware and Oregon Aves, manufacturer of chemical products, has filed plans for the erection of a new 1-story plant addition, estimated to cost $20 000

BOWMANSTOWN—The Aluminum Pigment & Products Co, Bowmanstown, recently organized, will locate its proposed new plant at this place instead of at Lehighton, Pa, a previously announced A general contract for the building has been awarded to Charles Fenstermacher, Lehighton, and a portion of the initial equipment installation will be handled by the Fuller Lehigh Co, Fullerton, Pa The plant will be devoted to the manufacture of aluminum pigments

NEWCASTLE—The Grasselli Power Co has tentative plans under consideration for the rebuilding of its press mill, recently destroyed by fire. The estimated loss has not been announced Headquarters of the company are in the Guardian Bldg., Cleveland, Ohio

Tennessee

KNOXVILLE—The Cherokee Brick Co. has purchased a tract of more than 20 acres of land in the Chestnut Ridge section, and plans for the early erection of a new brick-manufacturing plant, with initial daily output of about 40,000 bricks. The company was organized recently with Roy Newman as president, and J. C. Wright, secretary and treasurer.

ERWIN—The Southern Potteries Co., recently taken over by new interests, has tentative plans under consideration for the construction of a new unit, comprising about seven kilns, with various production departments. Other improvements will be made at the pottery for increased output. Charles W. Foreman heads the company. G F Brandt is in charge of factory production.

Texas

DALLAS—The Standard Spring & Axle Co, 2614 Main St., will install a heat-treating department at its new plant at 2816 Main St., on which work has been commenced. L. K. Weaver is president and treasurer.

SAN ANTONIO—The Kahn Oil Co. is planning for the installation of a new laboratory at its plant. C. H. Nunn is chemist, in charge.

Industrial Developments

CERAMIC—The Crescent China Co., Alliance O, is advancing production at its pottery and has commenced operations at the new 7-kiln plant, recently completed. The pottery will run full for an indefinite period.

The Auburn Shale Brick Co, Auburn, Pa, is arranging for early curtailment at its plant for necessary machinery repairs and plant improvements The plant will be closed for a few weeks and will then resume on a full capacity schedule

The Andalusia Brick Co, River Falls, Ala, is operating at full capacity and plans are under consideration for improvements to provide for greater output The company was recently acquired by new interests, headed by C L Benson

The E. H. Sebring China Co., Sebring, O, is running at full capacity with full working force, and will continue on this basis for an indefinite time The company has plans under consideration for the construction of two additional kilns at the pottery.

The Hazleton Brick Co, Hazleton, Pa, is making a number of improvements at its plant, including repairs to machinery, and plans to resume production early in the spring, giving employment to a full working force

The Gratztown Brick Works, West Newton, Pa recently acquired by new interests, has resumed production after a shutdown for about 24 months It is expected to maintain capacity operations for a number of months to come Eugene Servi heads the new company

Lenox, Inc, Trenton, N J, manufacturer of fine chinaware, has added a number of employees to its working force, including former operatives recently on strike, who have returned on an open shop basis, as lately established by the company. Operations are close to normal and will be maintained on this basis

RUBBER The Traveler Rubber Co, Bethlehem, Pa., is operating at full capacity with normal working force Incoming orders are in excess of the plant output and it is currently estimated that the company is now about 35,000 tires behind in deliveries Preliminary plans are under consideration for enlargements in the plant

In connection with proposed plans for maximum spring production, the Goodyear Tire & Rubber Co., Akron, O, has increased immediate output from 28,000 to 30,000 a day The mill is now giving employment to close to 14,000 workers Manufacture will be further advanced as soon as additional employees are available

The B F Goodrich Co Akron, O, has increased production in the tire departments at its mills from 18,000 to 20,000 tires per day A full working quota is being employed.

CEMENT—The Coplay Cement Co., Coplay, Pa, has resumed production at its Mill "B" following a shutdown for several weeks past, owing to necessary repairs and alterations in machinery. It is expected to develop capacity at an early date, with full working force

The Signal Mountain Portland Cement Co, Chattanooga, Tenn, is pushing construction on its new local mill, and expects to commence production late in April or early in May giving employment to a large working force The plant represents an investment of close to $2,000,000.

According to statistics compiled by the Portland Cement Association, mills throughout the country are running better than 65 per cent capacity, gross, an increase of 80 per cent as compared with this same time a year ago.

IRON AND STEEL—The Replogle Steel Co., New York, is making repairs at its large blast furnace at Catasauqua, Pa., including relining, with day and night working forces. The stack is expected to be ready for resumption within a few weeks.

The Wheeling Steel Corp., Wheeling, W Va., has blown in its Top Mill blast furnace, following a suspension since last August. The stack will give employment to about 100 men. All plant units of the company are now on the active list, operating at close to 75 per cent of normal.

The wages of puddlers and rollers in the Youngstown, O., district have been advanced 2.1 per cent and 2.5 per cent, respectively.

The Ulster Iron Works, Dover, N. J., are making ready to resume production at their puddling mills on West Clinton St. Plans are under way for extensions in the plant, to include the installation of two more furnaces and the erection of a mill to cost approximately $100,000. The working force is being increased in the different departments.

A total of 50 out of 51 steel mills are now in operation in the Niles, O., district, the single mill being that of the Mahoning Valley Steel Co, a shutdown of the unit being necessary on account of a breakdown. It is expected to be on the active list within a few weeks

MISCELLANEOUS—The Scott Paper Co., Philadelphia, Pa, is maintaining capacity production at its mills at Chester Pa., with employment of full working force This shedule will be maintained indefinitely.

The Tennessee Copper & Chemical Co, 61 Broadway, New York, has opened its new acid phosphate plant at Cincinnati, O., and will develop capacity production immediately It is said that the entire spring production of the new unit has already been completely sold

The Atlas Mineral Products Co, Mertztown, Pa, manufacturer of paint specialties, is running full with regular working force It is stated that orders on hand insure the continuance of this schedule for at least 6 months to come.

The Mathieson Alkali Works, Providence, R I is now operating at about 90 per cent of maximum capacity, as compared with less than 75 per cent at this same time a year ago

New Companies

THE CAMEL CHEMICAL CO., Portland, Ore., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are C W. Hall, W B Potter and George J Dreis The company is represented by S S Johnson, 909 Wilcox Bldg., Portland.

THE BURROWLITE NICKEL STEEL CO., care of the Corporation Trust Co. of America, du Pont Bldg, Wilmington, Del, representative, has been incorporated under Delaware laws with capital of $1 000 000 to operate a metal smelting and refining plant.

THE WAGGONER REFINING CO, Electra, Tex, has been incorporated with a capital of $300,000, to manufacture refined petroleum products. The incorporators are W. T, E P., and G. L Waggoner all of Electra.

THE MID-WEST WALL PAPER MILLS, INC., Fuller Tract, Logan Ave, Joliet, Ill, has been incorporated with a capital of $95,000, to manufacture paper products The incorporators are William E Lamb William M. Kearney and Thomas J Reardon.

THE FUNDY PAINT CO, Brooklyn N Y., care of E N Baar, 51 Chambers St., N. Y., representative, has been incorporated with a capital of $20,000, to manufacture paints, varnishes, etc The incorporators are E. R. Bagarozy and M Craushaar

THE SPRINGFIELD BRICK CO., Springfield, Mass, has been incorporated with a capital of $97,500, to manufacture brick, tile and other burned clay products Clayton H. Goodell is president, and Harold E Clark, treasurer, both of Springfield. The last noted represents the company.

THE ANGLO-AMERICAN ANILINE & CHEMICAL WORKS, INC., care of the Colonial Charter Co, Ford Bldg, Wilmington, Del, representative, has been incorporated under Delaware laws with capital of $450,000, to manufacture chemicals and chemical byproducts, dyes, etc

THE SWATARA CHEMICAL CO, Hummelstown, Pa., has been incorporated with a nominal capital of $5,000, to manufacture chemicals and chemical byproducts William Karmany, Hummelstown, is treasurer.

THE WEST VIRGINIA CHEMICAL CO., Fairmont. W. Va, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are J. M. Moran and H. H. Curry, both of Fairmont.

THE INTERNATIONAL PRODUCTS CO., 333 Ardmore Ave., Trenton, N. J., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, etc. The incorporators are John R Turner, Alfred F McCabe and Charles J. Hofman.

THE COLUMBIAN COLOR & CHEMICAL CO, Brooklyn, N. Y., care of Gilroy & Hyman, Woolworth Bldg., representatives, has been incorporated with a capital of $20,000, to manufacture chemical products, colors and affiliated specialties. The incorporators are J. J. and F. J. Sullivan, and J. R. Cusack.

THE ELLWOOD BRICK & TILE CO., care of Delaware Registration Trust Co., 900 Market St., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $75,000, to manu-

facture brick, tile and other burned clay products.

THE MARSHALL REFINING CO., 332 South Michigan Ave., Chicago, Ill., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Frank Sullivan, Harry N. Weinberg and Paul M. Godehn.

THE MONESS CHEMICAL CO, New York, care of A. M Silverman, 276 5th Ave, representative, has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are J. M. and E. Moness, and L. D. Malin.

THE BROOKS CHEMICAL CO, New Cumberland, W. Va, has been incorporated with a capital of $15,000, to manufacture chemicals, compounds, etc. The incorporators are C. L. Gray, John R. Platinburg and George W. McNeil, all of New Cumberland

THE LINSEED OIL PRODUCTS CO, Philadelphia, Pa., has been incorporated with a nominal capital of $5,000, to manufacture linseed oil and other oil products J H Webster, 34 East Willow Grove Ave, Philadelphia, is treasurer.

THE MANNING FERTILIZER CO, Manning, S. C., has been incorporated with a nominal capital of $50,000, to manufacture fertilizer products. Charlton Durant is president, and C. R. Sprott, secretary and treasurer, both of Manning.

Industrial Notes

MCCLELLAN & JUNKERSFELD, INC., engineer and contractor, of Philadelphia and New York, has added to its staff N B Ambler, J. T. Brusky, Harrison E Kleffel and Thomas Richardson. Renshaw Born has also recently been added to the staff and is in charge of the Philadelphia office at 112 South 16th Street.

THE CUTLER STEEL CO, of Pittsburgh, announces the appointment of W. F Furman as district manager, with headquarters at 50 Church St, New York. Mr. Furman was for many years with the American Locomotive Co and more recently the Eastern representative of the LeMoyne Steel Co, of Pittsburgh The general sales office of the company, which has been maintained for the past 2 years at 50 Church St., New York City, has been transferred to the Bowman Bldg., Pittsburgh, Pa. W. H Waddington, vice-president in charge of sales, will make his headquarters at the Pittsburgh address.

THE UEHLING INSTRUMENT CO., Paterson, N. J., has placed Royal E. Terhune in charge of the northern New Jersey sales territory. Mr. Terhune was formerly associated with the Uehling laboratories John E. Arnold, 15½ South 4th St, Tulsa, Okla, has been appointed an agent for the Oklahoma territory and H. R. N. Johnson, 917-A Marquette Ave, Minneapolis, has been appointed agent for the Minnesota, North Dakota and South Dakota territory. Walter C. Lange, 20 West Jackson Blvd, recently returned to the Chicago territory after 2 months spent at the Paterson plant, assisting in the development of the new Uehling CO, or combustible, recorder. This company also announces that it has appointed Mitsui & Co. representatives in Japan and China for Uehling CO_2 recording equipment and other Uehling power plant instruments and gages The head office of Mitsui & Co is located in Tokio and their New York branch is at 65 Broadway.

THE WEBSTER MFG CO, of Chicago, Ill and Tiffin, O, announces further expansion in connection with its Canadian business by starting a new corporation—Webster-Inglis, Ltd—which will be located at 14 Strachan Ave., Toronto, Ont., Canada The facilities of this plant will enable the company to design and manufacture elevating, conveying and power transmission machinery along the same lines as are now manufactured by the Webster Mfg. Co

THE HARRISBURG MFG & BOILER CO, of Harrisburg, Pa., recently opened a sales office in the Park Row Bldg., New York City. The company builds boilers, tanks, steel stacks, breechings and special steel plate and structural steel jobs. It also has large machine shops and makes a specialty of contracting to build entire lines of machinery for companies not having their own shops.

JOSEPH T. RYERSON & SON, INC., Chicago, Ill., announces that Clyde M. Carr has retired as president, on account of poor health. He has not taken an active part in the management of the firm for the past 2 years. He will continue, however, as a director. At the regular annual meeting of the directors, Joseph T. Ryerson was elected president. Joseph T. Ryerson, the grandson of the original Joseph T., succeeds to the presidency with a background of 22 years in the steel business. He was born in 1880 and immediately after graduating from Yale in 1901 went to work for the American Sheet Steel Co., now the American Sheet & Tin Plate Co., at its mill in Vandergrift, Pa. In October, 1902, he started with Joseph T Ryerson & Son at Chicago and in 1904 was elected treasurer, becoming vice-president in 1922

THE COMBUSTION ENGINEERING CORP., New York, announces that T J. Cleary, who has recently opened an office in Atlanta, Ga., for the sale of power plant equipment, has been appointed its Southern agent Communications should be addressed to Room 702, Candler Bldg. Atlanta, Ga.

THE KEWANEE BOILER CO is now located in its new building at 822 West Washington St, Chicago.

THE NATIONAL ANILINE & CHEMICAL CO., INC, announces that E. L Rimbault, formerly reclamation manager of the company, at the Buffalo plant, has been appointed manager of the intermediates and certified food color divisions. Mr Rimbault will be located at the main office of the company at 40 Rector St, New York City.

THE MONSANTO CHEMICAL WORKS, St. Louis, Mo., announces that at its annual meeting on Jan 15 the stockholders elected the following directors to serve during 1923: John F. Queeny, Gaston Du Bois, Beverly D Harris, Edgar M. Queeny, H O. McDonough, Joseph D. Lumaghi and Theodore Rassieur At the directors' meeting immediately following, the officers were elected as follows: Chairman of the board, John F. Queeny, president, Beverly D. Harris; first vice-president, Gaston Du Bois; second vice-president, Edgar M Queeny; third vice-president, Frank L. McCartney; treasurer, H. G. Gunther; secretary, W. R. Phemister, assistant secretary, C. A. Zacher Frank L. McCartney's title is now vice-president in charge of sales, while Edgar M. Queeny is vice-president and assistant general manager.

DWIGHT P ROBINSON & CO, INC., New York, has added as consulting materials engineer C. L. Chapman. Mr. Chapman, who has been active in the work of the American Society of Testing Materials and the American Concrete Institute, will, in the future, represent Dwight P Robinson & Co. in the committee work of these societies

THE POWER SPECIALTY CO. announces that Paul T. Buckler, for 14 years with the Detroit Stoker Co as manager successively of the Pittsburgh, Cleveland and New York offices, is now in its New York Office, assisting in the sale of Foster superheaters and economizers

THE WESTERN PRECIPITATION CO, Los Angeles, Calif, has moved its Eastern office from Philadelphia to New York City This applies as well to the office of the subsidiary company, the International Precipitation Co The Eastern office is now in the same quarters as those occupied by the company's associate, the Research Corporation, at 25 West 43rd St.

THE CONVEYORS CORP. OF AMERICA, Chicago, Ill., announces the acquisition from the Green Engineering Co, East Chicago, Ind., of all rights to the Green steam jet ash conveyor, the transaction having become effective Feb 1. It acquires all the patterns, patents and manufacturing rights pertaining to the Green conveyor All orders for replacement parts and extensions to the Green conveyor will be filled by the Conveyors Corp of America

THE ELECTRO BLEACHING GAS CO, manufacturer of liquid chlorine, announces the advancement to general sales manager of S W. Jacobs, succeeding D. K. Bartlett, resigned Mr. Jacobs is a chemical engineer and has supervised the installation of a number of chlorine plants His office will continue to be at the main office of the company, 18 East 41st St, New York City.

THE HARRISBURG PIPE & PIPE BENDING CO, Harrisburg, Pa, at a meeting of the board of directors, elected Christian W. Lynch president and director of the company, to fill the vacancy caused by the resignation of Alfred K. Barker Mr. Lynch up to the last year was president and general manager of the Harrisburg Foundry & Machine Co, Harrisburg, Pa., and prior to that was for many years president and general manager of the W. O. Hickok Mfg Co., Harrisburg, Pa

THE MERRIMAC CHEMICAL CO, 148 State St, Boston, Mass, announces that it has added to its list of products the following: Merclor, a bleach and disinfectant to be used in laundries, dairies, freight cars, markets, etc., and acetic acid in strengths from 56 per cent to glacial.

THE NEW YORK TESTING LABORATORIES, New York City, has installed a new automatic 100,000 lb. Tinius Olsen testing machine for handling of tensile tests, compression tests, transverse tests, etc.

THE ALEXANDER MILBURN CO., of Baltimore, Md., manufacturer of oxy-acetylene welding and cutting equipment, has recently placed on the market an addition to its line, viz., a portable acetylene welding generator designed to obviate the use of high-pressure cylinders. The company says: "The generator is of 30 lb. carbide capacity, or equivalent of 150 cu.ft. cylinder gas. It is simple to operate, having few parts, operates automatically with no clock or motors; steel body welded throughout, and all parts easily 'get-at-able'."

Coming Meetings and Events

AMERICAN ASSOCIATION OF CEREAL CHEMISTS will hold its ninth annual convention at Hotel Sherman, Chicago, June 4 to 9.

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va., May 7 to 9.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O., April 28 to May 4.

AMERICAN GAS ASSOCIATION will hold its annual convention the week of Oct. 15 at Atlantic City. An elaborate exhibition of gas-making and gas-utilization equipment is planned.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting June 20-23 at Wilmington, Del

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Eastman Hotel, Hot Springs, Ark., April 30 and May 1.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 10 and 11 at the House of the Institution of Civil Engineers, London, S. W. 1.

NATIONAL ASSOCIATION OF MANUFACTURERS OF THE UNITED STATES OF AMERICA will meet in annual conference May 14 to 16, inclusive, at the Waldorf-Astoria, New York City.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH) will be held in New York Sept. 17-22.

NATIONAL FOREIGN TRADE COUNCIL has postponed its annual conference from April 25, 26 and 27, to May 2, 3 and 4. It will be held in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

FIFTH PAN-AMERICAN CONFERENCE will be held at Santiago, Chile, March 25, 1923.

SOCIETY FOR STEEL TREATING—Eastern sectional meeting will be held June 14 and 15, in Bethlehem, Pa.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City; March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Salaries for Public Servants

BRIGHTENING the closing days of Congress, Representative UPSHAW of Georgia introduced a bill to increase Congressional salaries from $7,500 to $10,000 a year. In support of his measure he quoted no less an advocate than the late FRANKLIN K. LANE, to the effect that men in government service should be better paid. From the flowers of Mr. UPSHAW'S rhetoric we glean information to the effect that conditions have so changed since the present rate of compensation was fixed that it is now impossible for Congressmen to live properly and in a seemly fashion on less than $10,000 a year. He painted a pitiful picture of Congressmen borrowing money with which to take themselves and families back home.

We should be the last to gainsay the assertion that the cost of living has gone up; and we know from experience that Washington is an expensive city. But our meditations follow those of the late Secretary LANE even more closely than do those of Congressman UPSHAW, for the latter is thinking of Congressional salaries only, while the former was known to have had the deepest concern for the welfare of scientific and technical employees of the government, most of whom are notoriously underpaid. Our thought goes out to examiners in the Patent Office, whose lot was recently improved in some degree, and to chemists, physicists, geologists and other scientists, engineers and men of learning who worry along in the various government scientific bureaus on $1,800, $2,500 and $3,600 a year. Years of service and unusual ability may eventually carry them to the dizzy summits of affluence in civil service with a reward of $4,000 or $5,000 per annum.

It is neither unfair nor intended to be unkind to compare the qualifications and pay of these scientific servants of the government with those of its political representatives. We admit the comparison is odious, but we cannot help remembering that scientists in the government service are required to show special and extraordinary qualifications for the work they desire to do. They are tested and examined to determine their eligibility. Rules and regulations are laid down, and only through their strict observance do we permit these men of knowledge and scholarship to work for the people. And for all these requirements the remuneration is about 60 per cent honor and 40 per cent coin of the realm. Against this picture paint the corresponding qualifications and pay of Congressmen: local popularity, persuasive oratory, political regularity, a campaign fund, and a salary disproportionate to the intrinsic value of the service rendered.

All this, however, is far from proving that the pay of Congressmen should not be increased. But we should like to see it done on the basis of special qualifications for the job. Perhaps our point would be driven home with greater effect if Congressmen were engaged on a civil service basis—required to prove by test and examination that they are specially qualified for their work. Without boasting, we think we could organize an examination that would result in a marked improvement in the competence of our great law-making body. We should be inclined to ascertain the measure of intelligence of each candidate and his knowledge of public affairs, economics, finance and business. Oratory, on the other hand, we should rate very low; indeed the addiction to impassioned oratory would be regarded as a disqualification. Then when we had thus selected our Congressmen we should pay them such salaries as are now given to other civil service employees of exceptional and proved qualifications—and await the result. It is not at all certain that even under these conditions we could keep Congressional salaries from running away from those of government scientists, but we feel quite sure that in the first shock of realization there would be a tendency to increase salaries all around. If Mr. UPSHAW would give due consideration to the technical employees of the government we should have more sympathy for his proposal.

Another Boost For Lignite

RESULTS obtained during the past year by the United States Bureau of Mines in carbonization of lignite have attracted a great deal of favorable notice. Indeed, they indicate more promising opportunities for lignite briquets than have ever been prophesied before. As a natural consequence of this important development the Canadian authorities, who also have been studying this subject, are now concerning themselves directly with the methods used by the bureau.

This work now takes very definite form in an arrangement whereby the Bureau of Mines will act as consulting engineer for the Lignite Utilization Board of Canada. Under this arrangement the bureau will design an oven to be built by the Canadian investigators in connection with their plant at Bienfait, Sask. This new installation will follow closely the lines of the simple internally heated retort which was operated so successfully at Grand Forks last summer. Thus we have further evidence of the success of the co-operative agreement under which the bureau and Professor BABCOCK, of the University of North Dakota, have been working.

The new type of oven does not provide for gas or byproduct recovery. By some this may be regarded as a return to the old beehive oven principles; as a matter of fact, it is substantially that. But the oven gives results that promise to be commercially as well as

technically successful, and that is the true measure of industrial achievement. It would have been more satisfying to our technical sense of conservation of all products from raw materials if the tar, ammonia and gas, which theoretically might be evolved from lignite, could also be saved. But equipment that would recover these byproducts is far too costly both to build and to operate for greatest present-day success in lignite processing. The bureau very wisely, therefore, chooses a method that has commercial prospect of success in furnishing a smokeless domestic fuel for states otherwise far from sources of such material. It will be time enough later to add the refinements of design and operation when the basic work of the industry, manufacture of lignite briquets, can stand on its own feet financially.

Making a Fetish Of Secrecy

TOM MIDGLEY said not long ago: "When you bolt the door of your research laboratory, you're locking out more information than you're locking in." He was enunciating a principle of open-mindedness that has characterized the automobile industry and has been responsible for much of its progress. In this principle there is a lesson for many of our chemical manufacturers, particularly those affected by the German blight that surrounds a part of our industry with an air of mystery and secrecy. The war did much to improve this condition, but it did not eliminate it. Many chemical plants, making standard products by well-known processes, have closed their doors to the outside world in order to guard more carefully their precious manufacturing "secrets."

It has been our experience that it is in those plants where the German influence is most pronounced that the greatest reserve is maintained. Sometimes this is carried to a degree that is ridiculous. We recall the case of a fine chemical factory established here many years ago by some German chemists and engineers. The plant burned down recently and has just been reconstructed under the direction of the original superintendent, Herr Doktor B. When the architects drew up the plans for the new building, the superintendent insisted that all dimensions and proportions be given incorrectly in the specifications in order to make it more difficult for anyone to copy or duplicate the installation. When the equipment was ordered special scales were provided for reading all thermometers and gages, and only the superintendent had record of their real calibration. Another interesting precaution was the insistence that the aluminum kettles used in the process be painted black, so that if any of the competitors observed them during shipment, there would still be a mystery about their construction. These are but a few unimportant observations, but they are prime examples of suspicious and self-centered policies maintained by a few of our chemical manufacturers. It is perhaps significant to point out that after the chemical plant we have just mentioned was completed, serious difficulties were encountered in one of the distillation operations. Rather than call in a recognized consultant who was expert in such matters, the superintendent made an expensive trip to Germany and at a high cost purchased the information he needed from an employee of one of his foreign competitors.

But the German chemist is not the only one to worship at the shrine of secrecy. JOHN P. HARRIS makes the statement in an article in *The Cotton Oil Press* (extracts from which appear elsewhere in this issue), "that the art of edible oil refining has progressed less since its inception than any other branch of applied chemistry . . . because practically all of the manufacturers have made a great fetish of secrecy, even introducing it into their own organizations so that only the chosen few shall know of the 'wonderful secrets' by which their efficiency is obtained." He shows very clearly the industry's need for real co-operation in the free exchange of technical information and in the common effort to advance the industry by improving the quality of its products.

There is sound logic in this doctrine and the chemical engineering industries will find that removing the millstone of secrecy from about their necks is one of the surest and quickest steps toward technical and scientific progress.

How They Do It In England

PLENTY of criticism has been directed at the National Research Council. Many times we have been tempted to join the chorus of disapproval. An organization that is all overhead, that has funds with which to "start" and "co-ordinate" researches (some derivative of the word *liaison* should be used here, despite early acquaintance with the nasty word in the novels of DAUDET and BALZAC), but which has no money to prosecute investigations—such an organization is sure to be an easy butt of ridicule.

Undoubtedly it would be more desirable to describe a better method. So at the risk of being suspected by the Hearst publications of being pro-British, we should like to call attention to the activities of their Government Department for Scientific and Industrial Research. This was formed to organize and foster industrial research. As a matter of fact, this department controls the activities of the National Physical Laboratory—corresponding somewhat to our Bureau of Standards—but in addition it has done one thing since the great war. During those red years, science was found to be of value not only to the government but to industry as well. Particularly has the awakening occurred in the metallurgical industry in its many branches—steel making, iron founding, non-ferrous alloying, rolling mills and heat-treating shops. So this national organization has brought together the firms in various branches of industry into several research associations, which are charged with the duty of fostering, organizing and *paying for* researches into practical matters affecting the industry. For instance, nearly all the big and little firms making brass and bronze have joined the Non-Ferrous Metals Research Association. Financial support is apportioned according to the size or output of the member, and the government matches the expenditures for research, pound for pound, for 5 years. Ten different investigations into common troubles are now under way. Each of the studies is costing up to £2,000 per year and they are prosecuted at various laboratories fitted to carry them on. Others of them, such as the cause of red stains in brass, are being done at the National Physical Laboratory.

Another active organization in the metallurgical trades is the British Cast Iron Research Association.

It has a membership of 202 foundries and has the good fortune of obtaining PERCY LONGMUIR as director of research. It has eight investigations actively under way, on such things as the grading of pig iron, molding sand, cylinder casting, corrosion-resisting irons, ladle linings, "draws and shrinks" in castings, and sulphur holes and hard spots.

Publication of the results of these investigations will eventually be made, although they will be divulged only to the members of the association for a specified time. However, the members are kept in touch with the progress in a unique and intimate manner: Lectures are arranged at various centers by the research staff and to which only members of the association are admitted. A full account of the investigation is then given, and demonstrations are made of recommended practice as developed by the research. Two objects are served in this manner: First, early confidential communication of the results of the research is assured to those who have given it financial support; and second, the investigator gets into close and immediate contact with that section of the industry chiefly interested in his work.

Joint activities of this sort are particularly fine because of the support by industry. Since the industries are helping to pay for the work, they are much more anxious to see the results and to make an attempt to profit thereby. Researches done by outsiders, and published, may be read, but inertia is so great that obvious applications toward individual works-practice may be, and too often are, long delayed.

Such accomplishments by our English cousins appear to be a particularly fine example of how to get a thing done. While the work is sponsored by a governmental department, there is no more compulsion on the part of industry to co-operate than there is in this country. The essential difference is that over there a fund is available to match, pound for pound, the contributions of industry, and the National Research Council would undoubtedly do well to compare the net results.

The Mystic Quest In Science

ON THE 19th of February it was 450 years since NICHOLAS KOPPERNIGK, known as COPERNICUS, was born at Thorn, in Poland of those days and later of Prussia. His uncle was a bishop. He studied law at the University of Cracow, astronomy (and canon law) at Bologna, and medicine at Ferrara. He was his uncle's private physician until the bishop's death in 1512, and then became canon of Frauenberg, after which (according to Dr. C. G. ABBOT in *Science* of Feb. 16) he exerted himself for many years as physician to the poor. His great work "De revolutionibus orbium cœlestium" was completed in 1530, but was not published until 1543, when the first printed copy was brought to the author on his death bed. The year 1543 was only 360 years ago. Let us bear this fact in mind for a few minutes.

The work to which we have referred contained the amazing, surprising, absurd and preposterous proposal that the earth is round like a ball and revolves about the sun! Now everybody knew that the earth was flat like a cake, that it was stationary, and that while a complex system of epicycles had been spun out by the learned to account for the peculiar motions of the planets, all the stars were in fact "lesser lights" and of little more importance than so many tallow dips. There was a plane above the earth and the stars—which was heaven—and another plane below the earth—which was hell. The sun was a big lantern which was raised every morning in the East, and in the evening was let down in the West. Anybody who wasn't insane and possessed of devils or in league with SATAN from choice (or by foreordination) could recognize these facts as facts. So this last and great work which followed a previous extensive treatise on monetary reform by the same author was kindly provided with a preface by his friend OSIANDER, who explained that the whole notion—observations, computations and all—was purely speculative. And it was probably well for COPERNICUS that he passed away in 1543 and not later. He had a proper funeral at all events.

His conclusions were supported by GALILEO, who was not born until 21 years after the death of COPERNICUS, and GALILEO, as we know, had his troubles for his thoughts. He was forced to deny any such foolishness on pain of torture. Not long before he died, in 1642, it is said that he ventured to say that the earth does move after all. But it was heretical to do so, and everybody knew he was wrong. That was 281 years ago.

Only 281 years ago, and this country was already beginning to be settled. Our Fourth of July dates from less than a century later. Now ideas have inertia, and continue to endure even when the reason for them is removed, just as we learn in our books on physics of the movement of material bodies. In economics they call such persistence the "drag." Nearly all our philosophy of life and our dogmas of ethics and religion and our institution of common law date much farther back than 1642. The Holy Inquisition has passed out, but its principles and habits of thought remain. The earnest pleading of ex-Secretary BRYAN against the theory of evolution is an instance of this drag of ideas.

Many persons acknowledge the vastness and immensities of space, but they continue to order their thoughts according to the Ptolemaic system, which we have theoretically abandoned, with its conclusions that spring from a belief in a little, measurable, domestic universe of which the earth is at once the nucleus and the principal substance. It is confusing to think of hundreds of thousands of light-years in connection with space while remaining sound in traditional doctrine. In fact, the world is very much bewildered in these days. Many of us don't know what to believe, and finally we settle the matter by believing in nothing but what we can see or hear. But we can see and hear so very little that it is not enough to give us a grip on life; to give us faith. Then from many of us comes a general denial and we let things go at that. This is the philosophy that GOETHE attributed to *Mephistopheles*, and he pointed to it as the road to destruction.

So the question arises whether the time is not approaching to order our thinking according to the newer and greater light of science and to venture into the field of metaphysics in the quest of faith and understanding. When ASTON computed the resolution of the fractional mass of the hydrogen atom into energy on the creation or organization of helium, did he not do this very thing? He surely sought the greater understanding. And out of the greater understanding there may emerge the greater faith. Is it not right and proper that men of science should seek it? We are in sore need of it.

Readers' Views and Comments

Marketing Of Ideas

To the Editor of Chemical & Metallurgical Engineering

SIR:—The business executive was speaking and he was talking about a subject you have frequently discussed in your columns. It was of his technical men and of their difficulties in selling themselves and their ideas that he was speaking. But, you ask, who is this executive? All that I can tell you is that he is vice-president and general manager of a large organization operating a string of plants extending from Chicago west to San Francisco. He is what is termed a self-made man; his formal education had been completed in the elementary grade school. Initiative, hard work and persistence had brought him to the top. The rungs on the ladder had not been forgotten. His old associates pointed with pride to his accomplishments and respected and admired him.

"Frequently," said he, "the technical man wonders why he does not attract a larger salary. He wonders why, when so many plans and products are brought to him for an opinion, and often this is the determining opinion of their worth or feasibility—why, when he seems such an important cog in the machinery of his organization, he should draw a salary of such modest proportions. It so happens that business pays its greatest dividends to him who risks the most, and since these dividends are in the medium of exchange, this means who risks the most money. To the initiator of an idea goes the long reward, provided he knows how to carry it to a successful conclusion, or, as is more often the case, knows how to attract men to him who know the details upon which the success of the enterprise is dependent. Speaking for our own organization and from my experience with other similar organizations I should say that the technical man is seldom the initiator of the type of idea which is possible of successful commercial application. Usually our technical men act in the capacity of consultants to whom a proposition is submitted after it seems commercially feasible. The scope of their work is necessarily limited as compared with that of some of our executives.

"Compare for a moment my work with that of Dr. ——, head of our technical department. As in any organization, the worth of a man to us can be determined by a glance at his salary check. Why is mine greater than his? Simply because I am worth more; I can bring to this organization business on which we show a profit and because all of his duties are only one part of mine. To me is assigned the task of initiating projects and pushing them to a point where they become financially profitable; to him falls the duty of helping me with the technical details of these projects. I am not the only source of energy or ideas in this organization; if I were, it would not deserve that name.

"Sometimes ideas come from the technical department which are possible of profitable application, but, and note this, our technical men, who, by the way, are as able and wide awake as any, can carry these ideas only through the laboratory and to the plant. They can bring them to the point where large-scale production is possible, but there they stop. To someone else then must go the finishing of the job. Developing a process is an important thing, but so managing production and sales of the article produced that it will return a profit to those who have risked money in its manufacture is vastly more important, and incidentally more profitable.

"Take this message back to your technical friends who are dissatisfied with their money-earning capacity. Until they are able to plan a venture, supervise its details and bring it to a point where its returns will more than earn the rental of money invested in it—until that time must they remain relatively unimportant cogs in the machine, responsible for only a part of its operation."

And thinking about this on the way home, what "Sid" said in the *American Magazine* some time ago came back to me with a new force. "How many payrolls are you on?" he asked. "How much did you draw in your *pay* envelope last month, and how much in your *satisfaction* envelope?" I wonder how many of us have answered these questions before we voiced our complaints about the meagerness of our pay envelope and the lack of appreciation of our efforts by business?

ADOLPHUS.

Production of Sodium Sulphide

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest the articles on Sodium Sulphide which you have published in three recent issues of your journal and note the difficulties encountered by some.

For the manufacture of fused product I have never found any better installation that the reverberatory furnace, and even here the upkeep is very high on account of the action on the lining. However, where one wishes the 30 per cent crystals, I have had excellent results on a manufacturing scale from the batch rotary and the continuous rotary.

Some years ago I carried out experiments on a batch rotary for a chemical company in the South and obtained a reduction of 96 per cent of the theory using a charge of 1,600 lb. of coal to 2,000 lb. of salt cake and maintained my temperature between 750 and 850 deg. C. Much better and more economical results were obtained from a continuous rotary furnace using a charge of 2,000 lb. salt cake, 600 lb. of coal and 1,000 lb. of coke or residue from the leaching vats, maintaining same temperature as stated above. This gave 96 per cent of the theory, and one remarkable thing about it was it required no outside heat after it was once started. Due to the coke in the smelt it also obviates the filtration troubles. The sodium sulphide crystallized from the leachings of this material and dried and slightly washed in a centrifugal is practically chemically pure.

How Does Idleness Affect Profits And Selling Prices?

The Executive's Problem of So Adjusting Prices as to Increase Sales and Total Profits When a Plant Is Not Operating at Capacity Involves Considerable Computation—A Simple Method of Solving the Problem Is Described in This Article

BY F. P. MULLANEY
Of Mullaney & Co., Consulting Engineers, Chicago, Ill

IN normal times many articles are written telling how to increase profits. In dull times the question of how to reduce losses is given considerable attention. At present business has reached the point where it cannot be considered either normal or dull. While all indications point to a slow but consistent increase in the demand for manufactured products rather than a tendency to revert to a demand so small that business is considered "dull," still very few industries are running full capacity. This means that there is a certain amount of idle equipment in nearly every line of industry, which, of course, results in a loss of money.

The problem confronting the business executive today is how to increase the demand for his product so that the factory can be run at a greater capacity. While the demand for a product of a factory can usually be stimulated by a reduction in selling price, an executive cannot consider taking this step unless he has a very complete picture of the effect that a reduced selling price will have on the final profit of the business. The first question he must decide is, "Will a reduction in selling price increase the demand for the product?" The next question is of the following nature: "How much can the selling price be reduced, if doing so will increase the demand for the product and still enable the company to make the same net profit?" A selling price slightly greater than this will result in an increase to profits, although the price finally set may still be considerably lower than the present selling price. All of this assumes that the reduction in price will actually increase the volume of sales.

It is the purpose of this article to discuss, first, the relation which plant capacity has on final profits, and then present a chart for the convenient ready solution of the problems involving this relationship.

Every manufacturing plant has a certain definite expense which is incurred regardless of the amount produced. This expense consists of rent of buildings, interest, taxes, insurance, maintenance, depreciation and other fixed charges, and is generally known as "Constant Expense." If the factory is running at its full, or normal, capacity, the constant expense per unit produced is relatively small. However, if the factory is running at only a fraction of its capacity, say one-half, and turning out only one-half of its normal production, the amount of constant expense incurred per unit produced is twice as great as the desired minimum.

Some accounting systems charge the constant expense, no matter how large, against the amount produced, no matter how small. Under such a system the loss incurred shows up as an increase in the cost of production. It is becoming generally recognized that the cost of each unit of product should include only those expenses which contributed to its production and that, therefore, the constant expense should be spread over the normal capacity of the shop. Under this method, the amount of constant expense charged against the output of the factory bears the same ratio to the total constant expense as the amount produced bears to the normal capacity of the factory. Any portion of the constant expense which is not charged to the product, due to the fact that the factory has not been run at full capacity, is charged as a loss against the business. Thus, in a plant running one-half capacity and turning out one-half of its normal production, one-half of the constant expense represents the loss incurred—in other words, the cost of idleness. Of course, the cost of idleness decreases as the used capacity of the shop increases.

Entirely regardless of the accounting method used, the fact remains that, all other factors remaining the same, an increase in the volume produced and sold will not only increase the total income of the business, but will at the same time increase the profit per unit produced. This is because the fixed charges, or "Constant Expense," are less per unit produced. To indicate the similarity between both methods of charging constant expense, let us take a plant the full normal capacity of which is 200 units, but which is using only 50 per cent of its capacity and turning out 100 units. At full capacity the cost is, say, $100, of which $15 represents the fixed charges or constant expense. The accounting methods compare as follows:

	Constant Expense Distributed Over—	
	Amount Produced	Normal Capacity
Quantity produced	100	100
Per cent of capacity used	50	50
Unit cost	$115	$100
Unit selling price (est.)	$150	$150
Unit profit	$35	$50
Total profit	$3,500	$5,000
Loss due to idleness	...	$1,500
Profit after idleness	$3,500	$3,500

In order to study the relation among capacity, selling price and profit, it is only necessary to determine the loss incurred as a result of running the plant at the various rates of capacity less than normal. It is not necessary to change the accounting method, providing the present method indicates the amount of this loss.

Let us take as an example a factory running at 40 per cent capacity. In this case 60 per cent of the constant expense is the cost of idleness. If enough work can be secured to run at 70 per cent capacity, this loss

will be reduced to 30 per cent of the constant expense. Therefore, because of the reduction in the cost of idleness, the selling price can be reduced an amount equal to 30 per cent of the constant expense and the business will still make as much profit as was made previously.

THE PROFIT COMPARISON CHART

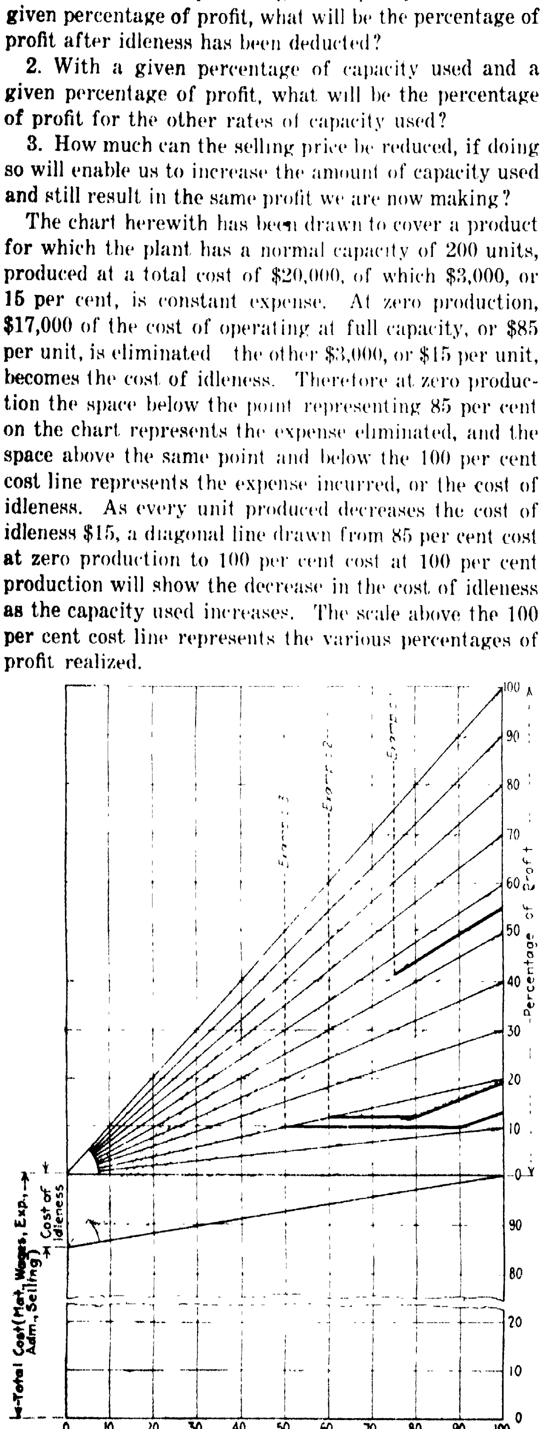
The "Profit Comparison Chart" has been devised to answer the following questions:

1. With a given percentage of capacity used, and a given percentage of profit, what will be the percentage of profit after idleness has been deducted?

2. With a given percentage of capacity used and a given percentage of profit, what will be the percentage of profit for the other rates of capacity used?

3. How much can the selling price be reduced, if doing so will enable us to increase the amount of capacity used and still result in the same profit we are now making?

The chart herewith has been drawn to cover a product for which the plant has a normal capacity of 200 units, produced at a total cost of \$20,000, of which \$3,000, or 15 per cent, is constant expense. At zero production, \$17,000 of the cost of operating at full capacity, or \$85 per unit, is eliminated the other \$3,000, or \$15 per unit, becomes the cost of idleness. Therefore at zero production the space below the point representing 85 per cent on the chart represents the expense eliminated, and the space above the same point and below the 100 per cent cost line represents the expense incurred, or the cost of idleness. As every unit produced decreases the cost of idleness \$15, a diagonal line drawn from 85 per cent cost at zero production to 100 per cent cost at 100 per cent production will show the decrease in the cost of idleness as the capacity used increases. The scale above the 100 per cent cost line represents the various percentages of profit realized.



PROFIT COMPARISON CHART

Solid lines: profit after deducting cost of idleness. Dotted lines: profit before cost of idleness is deducted.

Lines drawn from the point representing 85 per cent cost at zero production to the points representing the various percentages of profit will show the percentage of profit before deducting the loss due to idleness. Lines drawn from the point representing 100 per cent cost at zero production to the points representing the various percentages of profit will show the percentage of profit after the cost of idleness has been deducted. On this chart dotted lines denote the profit before deduction is made for the loss due to idleness. The solid lines denote the profit after this deduction has been made.

HOW TO USE THE CHART

Through the use of a "Profit Comparison Chart" the profit before idleness at any capacity can be converted to terms of profit after idleness without the necessity of detailed figuring. Profit after idleness can likewise be converted to terms of profit after idleness. For example: 60 per cent profit before idleness at 75 per cent capacity is equivalent to 55 per cent profit after idleness. (See example 1.) The result, 55 per cent, is obtained by scaling from the zero point of the solid lines, through the point representing 60 per cent profit and 75 per cent capacity on the dotted line, to the "Percentage of Profit" scale at the right of the chart.

Knowing the profit now made at a certain capacity, it is a simple matter to determine the percentage of profit necessary, at any other capacity, to make the same amount of profit. For example: If a factory is running at 60 per cent capacity and making a profit of 30 per cent before idleness, the same amount of money can be made and the product sold at a price equivalent to a 19 per cent profit before idleness, providing enough work is obtained to run at 80 per cent capacity. (See example 2.) This is determined by scaling from the zero point of the dotted lines, through the point representing the same "Percentage of Profit" at 80 per cent capacity as at 60 per cent capacity and 30 per cent profit before idleness, to the "Percentage of Profit" scale at the right of the chart.

Example 3 shows that if we are now running 50 per cent capacity and making a profit of 20 per cent after idleness, we can make as much profit by selling at 12.8 per cent profit before idleness providing we run at 90 per cent capacity. This is determined by scaling from zero point of the dotted lines, through the point representing the same "Percentage of Profit" at 90 per cent capacity as at 50 per cent capacity and 20 per cent profit after idleness, to the "Percentage of Profit" scale at the right of the chart.

CHANGES IN SELLING PRICE IN DIFFERENT TYPES OF ORGANIZATION

Manufacturing plants may be divided into two classes. The first class embraces those turning out a more or less standard product. By this we mean articles which are regularly catalogued and sold through various representatives. The selling price on the products of factories in this class cannot be changed with any great frequency, but the "Profit Comparison Chart" will be of value whenever the question of selling price is brought up. However, it should be borne in mind that the main object of the chart is to enable the executive to tell at a glance what effect increased sales will have on profit; or, in other words, to determine readily how much the selling price of a product can be reduced, without loss of income, by increasing the amount of plant capacity used. If the selling price is reduced and

enough goods are not sold to run the plant at the capacity expected, less profit will be made. Therefore the executive who uses these charts should be reasonably certain that a price reduction will accomplish the desired results before he takes definite action.

The second class embraces plants turning out articles on job or contract work. Factories of this class obtain work on estimates made on the different jobs after taking business conditions, the amount of work ahead of the shop, etc., into consideration. The executives of these plants will find the chart of great value because, knowing the shop capacity they are now using and the gross or net profits now made, they can readily determine how low they can bid on any job and still obtain the same or better results.

Petroleum Refining Gains 335.8 Per Cent in 7 Years

Output of Marketable Products in 1922 Valued at One and Three-Quarter Billions of Dollars

According to reports made to the Bureau of the Census, the value of products of establishments engaged primarily in refining petroleum amounted to $1,727,440,200 in 1921, as compared with $1,632,532,800 in 1919 and $396,361,400 in 1914, an increase of 5.8 per cent from 1919 to 1921, but an increase of 335.8 per cent for the 7-year period 1914 to 1921. The number of refineries has steadily increased from 76 in 1914 to 320 in 1919 and 336 in 1921. Of those reported for 1921, 67 were located in Oklahoma, 64 in Texas, 53 in Pennsylvania, 45 in California, 23 in Kansas, 16 in Louisiana, 13 each in Illinois, Ohio and Wyoming, 9 in New Jersey, 6 each in Kentucky and New York, 5 each in Indiana, Missouri and West Virginia, 4 each in Colorado and Maryland, 3 each in Arkansas and Massachusetts, 2 in Rhode Island and 1 each in Delaware, Georgia, Minnesota, Montana, South Carolina, Utah and Virginia.

Wage Earners and Hours Employed

In January, the month of maximum employment, 72,298 wage earners were reported; and in September, the month of minimum employment, 56,632; the minimum representing 78.3 per cent of the maximum. The average number of wage earners employed during the year was 63,197, as compared with 58,889 in 1919 and 25,366 in 1914. A classification of the wage earners with reference to the prevailing hours of labor in establishments in which employed shows that for 6,186, or 9.8 per cent of the total (average) number, the hours were less than 48 per week; for 27,471, or 43.5 per cent, they were 48; for 3,808, or 6 per cent, the hours were between 48 and 54; for 890, or 1.4 per cent, they were 54; for 23,294, or 36.9 per cent, they were between 54 and 60; and for 1,548, or 2.4 per cent, they were 60 or over.

TABLE I—STATISTICAL SUMMARY OF PETROLEUM REFINING, 1914-1921

	1921*	1919*	1914
Number of establishments	366	320	176
Persons engaged	74,291	73,473	31,077
Proprietors and firm members	55	59	52
Salaried employees†	11,039	14,525	5,659
Wage earners (average number)	63,197	58,889	25,366
Salaries and wages	$129,262,700	$116,368,700	$27,289,900
Salaries	27,940,300	26,619,000	7,892,400
Wages	101,322,400	89,749,700	19,397,500
Contract work	4,832,000	2,352,000	502,700
Cost of materials	1,382,425,000	1,247,908,400	325,264,500
Value of products	1,727,440,200	1,632,532,800	396,361,400
Value added by manufacture‡	345,014,800	384,624,400	71,096,900

* Figures for 1921 do not include establishments reporting products under $5,000 in value, thus excluding 7 establishments which employed 7 wage earners, and in the aggregate reported products to the value of $22,752. The figures for 1919, however, include 4 such establishments, which employed 2 wage earners, and reported products to the value of $10,996.

† Includes to some extent employees of sales and distributing departments.

‡ Value of products less cost of materials.

TABLE II—DETAILED STATISTICS OF PETROLEUM PRODUCTION, 1914-1921

	1921	1919	1914

*Figures not available

The statistics for 1921, 1919 and 1914 are summarized in Table I; the figures for 1921 are preliminary and subject to such change and correction as may be found necessary from a further examination of the original reports.

Detailed statistics of production for the years 1921, 1919 and 1914 are given in Table II. While the production in the group "naphthas and lighter products" increased 27.8 per cent in quantity, and 15.1 per cent in value since 1919, the increase in the output of gasoline alone was 39.7 per cent in quantity, and 23.7 per cent in value.

University of Minnesota to Have Experimental Blast Furnace

At the North Central Station of the Bureau of Mines, in Minneapolis, plans for the proposed experimental blast furnace for the University of Minnesota have been made. For the purpose of gaining assistance in the design of this experimental furnace, a careful study has been undertaken of the records obtained in 34 experimental runs on small-scale blast furnaces operated by the Bureau of Mines at Minneapolis since 1919. These records will also be studied in considering changes in the bosh and hearth of the furnace stack, now erected outside the Minnesota School of Mines building, which it is expected will be put into blast about the first of May. Several years ago a method of studying the lines of flow of stock in the blast furnace by the use of cardboard models filled with lead shot was developed. This device has also been used in testing the flow of stock in the experimental blast furnace proposed for the university.

Closure for Acid Carboys

A Review of the Report of the Committee Appointed by the Manufacturing Chemists Association

BEGINNING in May, 1920, shortly after the committee was asked to undertake the work and continuing throughout 30 months of active work, the carboy test sub-committee of the executive committee of the Manufacturing Chemists Association has completed a very valuable piece of work. The need for a study of carboy closure was great. Not only was there great unreliability in the average acid carboy closure but there was considerable danger in the use of cement and plaster of paris and other special closure agents from cracking and breaking the carboy lip. No satisfactory stopper or gasket was at hand, and considering the fact that thousands of carboys are used and shipped daily, the necessity of solving the problem was at once imperative and obvious.

The logical development of the work is intensely interesting and it is a pleasure to follow the systematic, ingenious and painstaking study involved. Starting with the three following statements of which the committee was reasonably sure, an investigation of stoppers, gaskets and stopper fastenings was begun:

1. Ground glass closures were entirely satisfactory if fastened in by any reasonably secure method.
2. Carboys with chipped necks should never be allowed for nitric acid.
3. Carboys with necks chipped as much as ¼ in. deep should be condemned.

The Ideal Closure

It will be impossible to discuss in detail the progress which was made. It is illuminating, however, to record the seven characteristics which the committee felt were desirable for an ultimately satisfactory solution to the closure problem:

(*a*) The closure must be vented in some way to prevent accumulation of pressure.

(*b*) The neck of the carboy must be sufficiently smooth to afford a proper seat for a gasket or else the gasket must be so made that it will fill all cracks and crevices.

(*c*) The stopper must be tough, well formed and uniform and must fit closely in the neck of the carboy.

(*d*) The gasket must be such as to afford a tight closure, must not be subject to disintegration through action of various acids, must not become solid so as to hinder removal, and must not discolor the acid through contact.

(*e*) The fastenings must be strong and secure and only slightly, if at all, affected by acid fumes. It must also be easily applied and removed.

(*f*) The entire closure should, if possible, be arranged so that an examination of it in place will show whether it is in good condition.

(*g*) The cost of the parts of the closure and of the labor of applying it must be reasonable.

Prevalent Type of Closure Prior to the Investigation

There were two closures in very general use before the investigation was undertaken. The committee collected considerable data on the specific criticisms of them.

Class I. The glass or earthenware stopper with a gasket, generally paraffined asbestos, held in place by a wire fastening of the "Brainerd" type or of the lever type such as the well-known "Gem" fastener. In this closure the glass stopper is easily broken; the earthenware stopper is frequently poorly designed and made and is sometimes brittle; no efficient venting is easily and surely obtained without the probability of leakage; the paraffined asbestos gasket or, in fact, any gasket of that type is efficient only when it has a nearly perfect seat; the wires of the fastener are frequently too light; and, if the carboy has a chipped neck, an additional coating of plaster of paris or some cement mixture must be applied, but such a coating has generally been found to be inefficient against handling or storage.

Class II. The earthenware (or occasionally glass) stopper sealed in place by means of plaster of paris or similar cement mixture, or possibly clay, applied between the flange of the stopper and the neck of the carboy and also coated over the entire stopper and top of the neck of the carboy and then inclosed in a burlap covering securely tied around the neck of the carboy; sometimes the burlap is further coated with tar or asphaltum. This closure is reasonably efficient when properly made and applied, but is especially undesirable because of the probability of the use of a poor cement mixture and careless application; it is also very liable to deteriorate in storage due to the cement becoming crumbly; the burlap covering frequently conceals the defects until too late to prevent accident.

Development of Stopper Design

Perhaps the first conspicuous progress was made with a porous earthenware stopper and about the middle of March, 1921, it was judged satisfactory. It had the following qualities in its favor:

1. It was hard and could be well shaped in manufacture.
2. It was tough and would withstand rough treatment without breakage.
3. It could be made as highly porous as necessary.
4. It was non-sulphating.

Later on a gasket was developed which gave great promise of filling the needs. It was made of a ½-in. rope asbestos soaked in a mixture of paraffine and oil. This is 50 per cent machine oil and 50 per cent paraffine and is heated and thoroughly mixed and the asbestos rope soaked therein for about 5 minutes and then run through a grooved wringer to remove surplus material, allowed to solidify and cut into proper lengths for use. This gasket is flexible, compressible and tough. Easy application, low cost, tight closure and no discoloration of acid was claimed.

The Progress Report in August, 1921

Conclusions that had been reached in August, 1921, were:

1. Glass stoppers ground to fit and secured in place by burlap or other suitable fastening allowed for all acids. Note: It was thought unnecessary to forbid the use of chipped necks or cracked necks with this form of closure.
2. Glass stoppers with gasket: Not to be allowed.
3. Porous clay or earthenware stoppers with gaskets and fastenings under the following conditions:

(*a*) Allowed for all acids.

(*b*) Stoppers must be made of material sufficiently porous to prevent accumulation of interior pressure under ordinary conditions of transportation. The M. A.

Knight standard porous stopper is to be considered as a minimum for porosity.

(*c*) Stoppers must fit fairly closely inside the neck of the carboy. Shank of stopper must be at least 1⅛ in. long and taper not more than ⅛ in. on the diameter. Stoppers must have two cross-grooves in the upper surface with minimum depth at top of ¼ in. and maximum width of ⅜ in. Stoppers must be tough and not brittle.

(*d*) Gaskets must be made of asbestos rope (not less than ¼ in. commercial) soaked in a mixture of 50 per cent machine oil and 50 per cent paraffine at a temperature of about 250 deg. F. and subsequently wrung out and allowed to cool; other gaskets of similar physical qualities so that they will remain plastic and not disintegrate during use are also allowed.

(*e*) The "Brainerd" or similar efficient wire fastening or a lever fastening of type similar to the "Gem" must be used. Note: The use of a screw thread on inside of neck of carboy with corresponding thread on the stopper is to be investigated.

(*f*) Chipped lips not allowed unless the package will not leak when gasket and stopper are in place and without using some additional means such as plaster of paris.

The wire must be "Armco" or other acid-resisting iron wire dipped in asphalt paint. The diameter of this wire should not be less than some minimum size which will be investigated and determined later. Possibly 0.1 in. (10 gage B.&S. or 13 gage Birmingham) will be all right for the Brainerd closure, while 0.15 in. will be proper for the lever type closure.

Material Progress in the Development of the Carboy Neck-Grinding Machine

About this time the carboy neck-grinding machine was completed, a description of which was published in *Chem. & Met.* (vol. 27, page 1267, Dec. 27, 1922). This was a condition greatly to be hoped for and was considered of the highest importance on account of the fact that chipped and cracked necks of carboys are among the greatest difficulties to be overcome in securing a tight closure. The work on this machine was pushed to a satisfactory conclusion and a separate report rendered. The special recommendation was summarized as follows:

That glass carboys used for the shipment of corrosive liquids must have an even surface around the mouth in which to seat the gasket; this surface must be at least ¼ in. in width for carboys of 7 to 13 gal. capacity and at least $\frac{3}{16}$ in. in width for carboys of less than 7 gal. capacity.

The development of this machine allows us to consider that all carboys may be prepared, before shipment, with a smooth surface for the gasket seat and thus do away entirely with the use of plaster of paris or other cement or clay mixtures, which have undesirable qualities, for the purpose of sealing.

Type of Wire for Fastening Also Studied

The investigation was continued to determine the amount of corrosion of wire fastenings when used with porous stoppers and also to endeavor to develop a wire-twisting device that would be more powerful and effective than the one ordinarily used for the Brainerd closure. A heavy type wire twisting tool was obtained after a very considerable delay and was tried out with heavy wire in several experiments, but without satisfactory results, as a strong tendency was noted to break the lip of the carboy due to the excessive pressure developed. Otherwise the tool and heavy wire were satisfactory.

Before formulating the final report certain special questions were brought up in a questionnaire, the answers being as follows:

(*a*) The venting of carboys closed by ground glass stoppers should not be recommended or allowed.

(*b*) The size of the inside diameter of the neck of carboy should not be recommended for standardization.

(*c*) The dimensions of cross-grooves in the upper surface of stoppers should be recommended as having a minimum depth of $\frac{5}{32}$ in. and a maximum width of $\frac{5}{16}$ in.

Final Recommendations of the Committee

The following recommendations were made by the committee and are reproduced verbatim from their final report:

General

1. The use of clay, plaster of paris and other similar mixtures for sealing carboys should be discontinued. It is possible to get a good seal in this way, but the high probability of getting a poor seal, the tendency of these mixtures to disintegrate during storage, the fact that a good seal is hard to remove and results in chipped and cracked necks, the fact that such a seal is frequently used to cover up serious chips and cracks in the mouth of the carboy, and the lack of necessity for such a seal when proper gasket, porous stopper and good flat seat on carboy mouth are used, make the use of such seals inadvisable.

2. Glass carboys used for the shipment of corrosive liquids should have an even, unchipped and uncracked surface around the lip on which to seat the gasket; this surface to be at least ¼ in. in width for carboy of 7 to 13 gal. capacity, and at least $\frac{3}{16}$ in. in width for carboys of less than 7 gal. capacity. The "neck-grinding machine" described, illustrated and recommended in our report of April 18, 1922, makes this condition a commercial possibility.

3. The stoppers for carboys should be required to fi fairly closely in the mouth of the carboy and have a taper conforming closely to the taper of the inside o the mouth of the carboy.

4. The size of stoppers should be standardized as nearly as possible at not more than ⅛ in. less diameter (approximately) than the inside of the carboy neck.

Stoppers

5. Glass stoppers, ground to fit, should be authorizec for all corrosive liquids, and should be secured in plac by wire, cloth, burlap or other suitable fastening.

6. Clay or earthenware stoppers, porous, should b authorized for all corrosive liquids; they should b made of a material sufficiently porous to prevent accu mulation of interior pressure under conditions of trans portation or storage; they should be tough and no brittle, and of such material as will not be disinte grated by the corrosive liquid contained in the car boys. These stoppers should be of such size that th shank will fit inside the mouth of the carboy with no over ⅛ in. clearance. The shank of the stopper shoul be at least 1⅛ in. long, and should taper not more tha ⅛ in. on the diameter; the upper surface of the stoppe should have two cross-grooves with minimum depth o $\frac{5}{32}$ in. and maximum of $\frac{5}{16}$ in., measured at the cente of the top; provided, that these stoppers, when mad

with screw thread to engage in corresponding threads on inside of carboy neck, need not have the grooves in their upper surface.

7. Glass stoppers (plain or screw, but not ground to fit), clay and earthenware stoppers (not porous) and other similar stoppers should not be authorized for mineral acids or for other corrosive liquids liable to develop considerable interior pressure; such stoppers may be properly authorized under suitable conditions other than the foregoing, but which should be determined dependent on the particular article being shipped.

8. Asbestos rope, treated, should be authorized for use for any corrosive liquid that will not seriously disintegrate the gasket during use; these gaskets should be made of asbestos rope (not less than ½ in. commercial) soaked in a mixture of 50 per cent machine oil and 50 per cent paraffine at a temperature of 250 deg. F. (approximate) and subsequently wrung out slightly and allowed to cool.

9. Flat asbestos, Rubberoid and other similar gaskets (not thoroughly plastic) should not be authorized for use for mineral acids or for other corrosive liquids liable to develop considerable interior pressure; they may be properly authorized under suitable conditions other than the foregoing, but which should be determined dependent on the particular article being shipped.

10. Other gaskets having physical properties similar to the treated asbestos rope gaskets, described above, so that they will remain plastic and not disintegrate during use, should also be authorized from time to time if found to be properly efficient in transportation and storage.

Stopper Fastenings

11. Wire fastenings of the type in which a wire is passed around the neck of the carboy just below the mouth and thence up over the stopper and twisted fast in a way to securely hold the stopper in place (such as the "Brainard" fastener) sould be authorized for all corrosive liquids; the wire should be required to be made of material as highly acid-resistant as practicable ("Armco iron" is recommended), and should be not less in size than No. 14 B.w.g. They should be coated with acid-resistant paint before using.

12. Wire fasteners of the lever type (such as the 'Gem" fastener) should be authorized for all corrosive liquids; the wire should be made of material as highly acid-resistant as practicable and should not be less in size than No. 9 B.w.g. They should be coated with acid-resistant paint before using.

13. Metal screw cap fasteners, consisting of a cap to screw down over the thread on the outside surface of the mouth of the carboy should be authorized for all corrosive liquids; the thread should be required to be heavy and rounded to prevent chipping and should be made so that, with gasket and stopper in place, at least two full threads will be engaged; these caps should be made of material as highly acid-resistant as practicable and not less than No. 18 gage U. S. Standard in thickness. The cap may be allowed to have a hole in the top.

14. "Screw thread on stopper" fastening in which a thread on the shank of the stopper engages in a corresponding thread on the inside of the mouth of the carboy should be authorized for all corrosive liquids; the thread should be required to be heavy and rounded to prevent chipping, and should be made so that, with gasket in place, at least two full threads will be engaged.

15. Action should be taken to advise all users of carboys in regard to the desirability of instituting and enforcing such of the recommendations mentioned above as are considered acceptable.

16. The Bureau of Explosives should be requested to take appropriate action at some future date such that all concerned will have ample opportunity to prepare themselves for the change, to make obligatory and effective throughout the United States and Canada such of the foregoing recommendations as may be acceptable.

Comparison Made on Prices of Cement

The Cement Information Service has recently issued a statement of the facts concerning cement prices, profits, production and distribution, in reply to charges brought against the cement industry as a whole. It is stated that during the early part of 1915 some companies sold cement at 60 cents a barrel at their mills—a price admittedly below cost. Never before in the history of the industry had cement prices dropped so low. Many manufacturers refused to sell their product at that figure. Being confronted with serious financial difficulties, some plants were obliged to close. In reference to this, the Cement Information Service states that it is not fair to take the price of a commodity at an abnormally low point and during a temporary period as an indication of what a reasonable price should be.

A comparison between the price of cement and that of other building materials indicates that the price of cement did not rise to the high point reached by other building materials. Cement prices are therefore extremely low, considered relatively or absolutely. Let us compare today's price of the essential elements in the cost of cement with the price in 1914: Coal per ton delivered at the cement mill in 1914 cost $2.45. Coal now costs $6 per ton. Labor in cement plants in 1914 received on the average 20.1 cents an hour and now receives an average rate of about 42 cents an hour. Gypsum per ton at plant in 1914 cost $2.75. It now costs $6.20 per ton. Bags per 1,000 in 1914 cost about $82. Now bags cost about $215 per 1,000 due to the rise in the price of cotton from 7 cents a pound in 1914 to about 30 cents a pound today, and it takes four bags to make a barrel of cement.

Selling expense is also an important item in the cost of cement. Nineteen Eastern companies report that selling expenses increased on the average from 6.4 cents per barrel in 1914 to 12.5 cents per barrel in 1921. When existing conditions are taken into consideration, present figures for cement compare very well with those prevailing in 1915.

Resistance of Flow of Ore Through Beds of Solids

A large-scale apparatus has been devised at the Minneapolis Experiment Station of the Bureau of Mines for measuring the pressure encountered by a stream of ore in its passage through beds of lumps of coke and ore. More than 150 tests have been made. Three sizes of coke were employed (pea, nut and stove) and in each case it was found that the pressure drop varies as the square of the weight of air forced through a given bed. As yet the effect of the size of the coke on its specific resistance has not been determined. Experiments for the three cokes individually have been made and the binary system pea coke-stove coke has been completed.

Secondary Structures in Steel

Steel Solidifies in Dendrites of Delta Iron; Transformation Into Gamma Iron Involves Recrystallization Into Independent Granules of Austenite; Further Change Into Alpha Iron Causes Three Varieties of Secondary Structure

BY COLONEL N. T. BELAIEW, C.B.

IN 1913 Prof. Federico Giolitti communicated a paper to the Academy of Science of Turin, giving some observations on a piece of metal "whose structure did not correspond to Belaiew's dicta." I received a copy of that paper from Professor Giolitti on the eve of the great war and was unable then to more than glance at it. So that very interesting paper remained unanswered.

Dr. Giolitti also published a series of articles on the structure of steel in *Chemical & Metallurgical Engineering* during 1920. In the first of these, on "Crystallography of Alpha and Beta Iron," he gives a critical survey of my published views on primary and secondary crystallization and scheme of the three main secondary structures—viz., the network structure, the Widmanstattian structure, and the structure of large crystals. Then Professor Giolitti proceeds to give his observations on a sample of sheet steel having 0.32 per cent carbon, which had been heated about 5 months continuously at from 900 to 1,050 deg. C. and then cooled with the furnace, requiring 4½ days to drop from 1,000 to 150 deg. C. He says: "Belaiew's views would require such a piece to have a reticular structure, yet this metal has very coarse crystals and perfectly developed Widmanstattian structure." Thus his idea that ferrite is ejected to the periphery of homogeneous austenite on very slow cooling is not confirmed by study of a really uniform metal, which then actually gives Widmanstattian structure."

Instead of the author's hypothesis, Dr. Giolitti holds that "hypoeutectoid steels, especially, can therefore be classified and their structure explained by the hypothesis that beta iron assumes a granular and alpha iron a laminar habit." The real point at issue between the two views is, therefore, whether a definite type of structure is more or less linked up with certain allotropic modifications of iron, or whether it is dependent on thermal treatment only. Some of the differences undoubtedly arise from the fact that Dr. Giolitti was consulting an imperfect abstract found in a German journal of my early writings.

THREE TYPES OF SECONDARY STRUCTURES

My views on secondary structures in steel were first presented in various papers read before the Russian Technical Society in 1908 and 1909 and subsequently published in my thesis "On Crystallization of Steel on Slow Cooling" (Petrograd, 1909). In 1912 they were traversed again at some length in French in the *Revue de Métallurgie*[1] and in 1920 in English in a paper read before the Institution of Aëronautical Engineers.[2] They also formed the bulk of my two first lectures on "Crystallization of Metals" delivered in 1922 at the Royal School of Mines (University of London).

In proposing my scheme of three secondary structures, I had in view two main considerations: to bring in evidence first the crystallographic relations, and second the relation between these structures and the various areas of the well-known iron-carbon equilibrium diagram (Fig. 1). One of the most important determining factors is also the influence of previous processes on the condition of the metal immediately before secondary crystallization would start. Therefore, there are two of such processes now to be taken into consideration: the solidification process or "primary crystallization," occurring in the mushy zone between the liquidus and solidus lines and the process of "granulation" taking place in the austenitic zone.

Primary Crystallization results in the formation of dendritic crystals or dendrites in every alloy. After

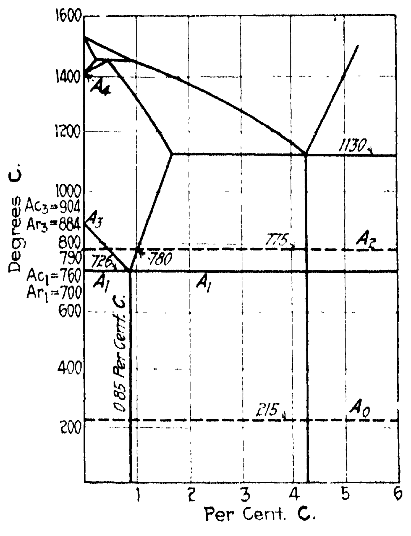

FIG. 1—IRON-CARBON DIAGRAM, AS PROPOSED BY HONDA

having completely solidified the alloy will be constituted of juxtaposed and interlocked dendrites. Every dendrite is a unit both from the crystallographical and chemical point of view. Alloys solidifying over a range of temperature—i.e., forming solid solutions—develop a chemical non-homogeneity in the dendrites which remains during its cooling and may be revealed at ordinary temperatures by proper methods. We say, therefore, that "development of macrostructure reveals dendritic structure."

The importance of primary crystallization has been sufficiently realized these last few years, and advantage taken of it. The same cannot be said about the subse-

[1] "Sur la Cristallisation et Structure des Aciers refroides lentement," *Rev. Mét.*, 1912, p. 321.

[2] "The Structure of Steel," *J. Inst. Aëronautical Engineers*, 1920, vol. 1, No. 3, p. 14.

quent phenomenon of granulation. A considerable amount of confusion appears to exist in the minds of several authorities, and the author feels compelled to re-cover the ground already traversed in his previous papers, some of which are quite inaccessible.

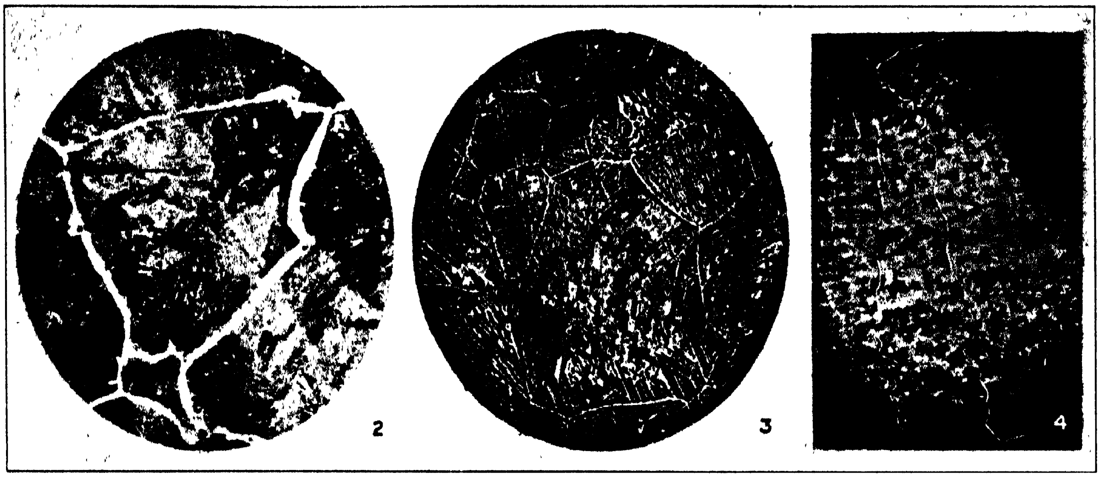
Granulation

On entering the austenitic zone every alloy is built up of dendrites; in leaving that zone, as the direct observations of Osmond and Baykoff show, every alloy is build up of "grains" or "granules."

The structure of dendrites (Fig. 4), as already mentioned, can be revealed by macro-etching - for instance by the method of N. I. Belaiew (diluted picric acid), by the cupric reagent of Stead and Le Chatelier, or by one of the "Damascene etchings." The structure of the granules can be revealed by etching the steel while in sequently of crystalline grains) are also altered. The general character of the process, however, remains the same and the resulting structures remain polyhedral, as appears to be true for all known allotropic transformations.

Therefore the present author has advanced the view that the granulation process is linked up and even caused by an allotropic change in iron. In his view the granulation zone is the one true gamma zone, while in the area of primary crystallization the iron is in another modification (as some authors suggest it exists in the delta state).

The final result of the granulation process is the breaking up of every alloy in a number of crystalline polyhedral grains, every such grain or granule being an allotriomorphic crystal. So it happens that the crystallographic unity of dendrites is destroyed in the



FIGS 2 TO 4 TRIAD OF SECONDARY STRUCTURES

Fig. 2—Network structure × 40. (Steel No. 5, carbon 0.60.)

Fig. 3—Widmanstättian structure. × 4 (Steel No. 8, carbon 0.60.)

Fig. 4—Dendritic structure with ferrite mesh × 1 (Steel No. 6, carbon 0.60.)

the granulation zone by the method of Saniter or Osmond.[3] The same structure is revealed afterward by secondary deposits.

Dendrites have become very familiar to us now and it is well to bear in mind that that structure is a macrostructure—i.e., a structure usually visible by a naked eye, hence the dimensions of dendrites are usually large. The structure of granules or the general picture of granulation is but seldom seen by an unaided eye; larger magnifications are needed and hence the name of microstructure. As a rule a great number of granules arise from one dendrite. The dimensions and distribution of the dendrites of primary crystallization depend on conditions of cooling during solidification. Correspondingly, the dimensions and distribution of the granules depend on the conditions of cooling in the austenitic zone. These processes are different and independent and the resulting structures are also different and independent.

The process of granulation is governed by the same laws as every process of recrystallization in a solid crystalline body—i.e., nuclei are appearing at a certain rate and transformation starts from these with a certain linear velocity. As the conditions of cooling are altered the number and distribution of nuclei (and subsequently of crystalline grains) ...

[3]"Microstructure of Iron and Mild Steel at High Temperatures," by H. S. Rawdon and Howard Scott, A.I.M.E., February, 1920, meeting. Chem. & Met. vol. 22, p. 787 (1920).

granulation zone; every alloy on leaving that area is built up of new crystallographic units. However, the chemical non-homogeneity of austenite (due to the mode of dendritic crystallization) remains, so that both of these structures can be revealed on every such alloy or piece of metal. Proper etching will reveal both the dendritic structure of primary crystals and the boundaries between the granules.

Decomposition of Austenite

It is in such an alloy, built up of a number of allotriomorphic crystals or granules, that the decomposition of austenite into the excess constituent and pearlite occurs. Every granule possesses its own crystallographic orientation and all the elements of such a grain are crystallographically identical; but where different grains meet there must be a kind of neutral zone, or "no man's land," where the crystalline matter cannot assume the orientation of either of the grains. This thin layer, which according to Beilby, Rosenhain and others is in an "amorphous" state, seems predestined to facilitate the ejection of the first particle of the crystallizing pro-eutectoid element, the latter tending to form an envelope about the remaining austenite. Given sufficient time and other suitable conditions the whole of the excess element will be ejected to the periphery of the grain, forming a membrane

of a certain thickness. On a plain section such structure will be seen as a cellular or network structure (Fig. 2). Thus arises one of three secondary structures seen in steel.

Widmanstättian Structure

If the whole of the secondary deposit had time to segregate in this way a pure "network structure" would ensue. The main condition is a correct relation between the size of the grain and the velocity of crystallization. It is easy to see that the larger the size of the grains the more difficult it is to expect that the whole of the secondary deposit would collect at the boundaries. Then, if the process were to continue at a more accelerated pace in a coarse-grained metal, a certain proportion of the excess constituent would be forced to crystallize out "on the spot"—that is, not at the boundary but in the middle of the grain, whereupon the habit and the orientation of the crystalline austenite would be the dominant factors controlling the shape of the deposits. Ordinarily the latter would arrange themselves along the cleavage planes of the mother crystals. Cleavage planes in an octahedral grain are parallel to four faces of the octahedron. Ferrite precipitated along such planes would build up the appearance of Widmanstättian figures on a section. These Widmanstattian figures together with the network form the "Widmanstättian structure." (Fig. 3.)

Structure of Large Crystals

The third possible type of secondary structures would occur if the secondary deposits would lodge themselves parallel to the axes of the dendrites, reminding one of the crystal skeletons of the macrostructure. That will occur in the absence, total or partial, of granulation. Then the crystallographic unity of dendrites remains undestroyed and the elements of secondary crystallization lodge themselves preferentially parallel to the dendritic axes. Such structures may be seen either in hypereutectoid steels, where the granulation zone is nearly absent, or in large steel crystals like the famous Tshernoff crystal, when the granulation zone was apparently passed too rapidly. Such structure the author calls the structure of large crystals. (Fig. 5.) Together with the Widmanstättian and the network structure it forms the triad of secondary structures.

In my opinion the occurrence of various secondary structures is thus explained without assuming with Dr. Giolitti that beta iron assumes a granular and alpha iron a laminar habit. By studying the secondary crystallization and the subsequent formation of pearlite grain I have never been able to find any crystallographic or structural difference between the alpha and beta varieties. Recent X-ray studies seem to confirm this view, while they also confirm the existence of the delta modification.

Genesis of Secondary Structures

A series of steels were made in 1907 and 1908 according to my directions at the Poutilov and Ijewsky Works in Russia. The carbon content was about 0.60 per cent for alloys Nos. 5, 6 and 8 and 1.80 and 2.20 for alloys Nos. 1 and 2 respectively. All these steels were prepared under the conditions indicated by Anossoff and Tshernoff for the manufacture of Damascene steels—i.e., cooled at an extremely slow rate—the area of secondary crystallization was passed very slowly indeed and the deposition of ferrite lasted not less than 2 hours. The process of granulation was also very marked in the hypo-eutectoid alloys, the granules growing sometimes as large as 7 sq.cm. in cross-sectional area. Steels Nos. 5 and 6, prepared at the Poutilov Works, exhibited a pure network structure, but on a very large scale. On the other hand, alloy No. 8, made at the Ijewsky Works, exhibited a splendid Widmanstättian structure. Hypereutectoid steels gave the structure of large crystals.

The conditions of cooling at the Ijewsky Works differed from those at the Poutilov Works in that the steel ingots were stripped earlier, presumably during the process of secondary crystallization. Therefore I arrived at the conclusion that Widmanstättian structure will be favored by a somewhat greater cooling speed in the interval of secondary crystallization. These conditions would be present either when the velocity of cooling through the secondary range is not excessively low, or when a marked undercooling occurs after a very slow cooling. If a steel is undercooled the secondary crystallization—i.e., the throwing out of the free element—proceeds at a considerable velocity in spite of

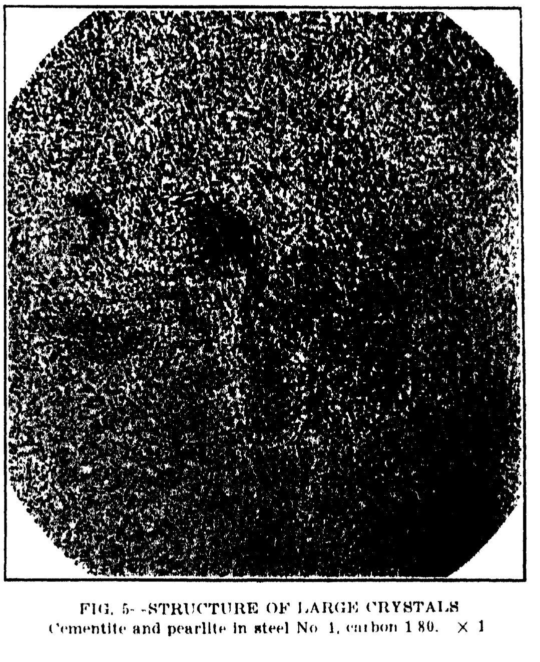


FIG. 5—STRUCTURE OF LARGE CRYSTALS
Cementite and pearlite in steel No. 1, carbon 1.80. × 1

the cooling being extremely slow, or the temperature even nearly stationary. In practice, this usually occurs in muffles, runners and the like; several instances were mentioned by the author in his thesis and have been noted by other writers.

The piece of sheet steel described by Professor Giolitti,[4] which had been heated for about 5 months continuously in the granulation zone and then cooled slowly, also comes under the heading. Its Widmanstättian structure is entirely in accordance with the present author's views. Here I would like to draw attention only to the importance of granulation and the size of the granules, in the production of such structures. The first and paramount condition for obtaining a well-defined Widmanstättian structure is the devel-

[4] "Crystallography of Alpha and Beta Iron," by Federico Giolitti *Chem. & Met.*, March 31, 1920, vol. 22, p. 585. Fig. 5 of this article is incorrectly described. It is a view of steel containing but 0.60 per cent carbon. Fig. 6 should also be called "Structure of Large Crystals."

opment of large grains of austenite while in the granulation zone. Once that is achieved, it will be comparatively easy so to modify the velocity of secondary crystallization as to cause the largest possible amount of the free element to crystallize out along the cleavages of the large granules and produce the Widmanstättian figures.

The smaller the granules the greater must be the speed of secondary crystallization to produce the Widmanstättian structures.

In my 1909 thesis I insisted on the importance of a uniform orientation of the elemental octahedra in the large granules as the most important preliminary condition for the subsequent development of Widmanstättian structure. In other words, each grain must be a true crystal, as far as its internal arrangement is concerned. In my later French paper (1912) I also dwelt on the relation between the size of the granules and the velocity of secondary crystallization, and on the importance of undercooling to produce Widmanstättian structure. It is regrettable that my views were rendered somewhat incorrectly and the illustrations wrongly labeled in the text which was mainly used by Professor Giolitti.

It is very difficult to bring out simultaneously the white ferrite mesh of the network structure and the dendrites of primary crystallization. I attempted to show that the "dendritic" structure as a rule is in no way related to the secondary structure; in some cases one dendrite is cut up in a multitude of granules, in another, one granule or one ferrite mesh contains several dendritic systems. That idea has been considerably developed by the present author in his French paper and in the publications following. I should therefore like to take this opportunity of saying that on this point I am in complete agreement with the views of Professor Giolitti and would like to indorse the conclusions of the latter's paper on the "Relationship Between Dendritic Structure and Ferrite Mesh"[5]; I feel, however, that if rightly interpreted the dendritic structure showing thin ferrite meshes shown in Fig. 4 could find its place in the latter paper, alongside Professor Giolitti's very interesting photos.

SUMMARY

To sum up, the present author believes that by suitably altering the velocity of cooling through the granulation zone and the zone of secondary crystallization any one of the three types of structures can be produced. So, for instance, my alloys Nos. 5 and 6 with 0.60 per cent C exhibit a macroscopic network structure; alloy No. 8 (C = 0.55 per cent) is a typical example of Widmanstättian structure, and my alloy No. 1 shown in Fig. 5 exhibits the structure of large crystals. The famous Tchernoff Crystal (C = 0.60 per cent) is the classic example of the structure of the latter.

This shows that the type of structure "depends in the first instance not on the chemical composition, but on the conditions of cooling, and brings into evidence the importance of crystallographic relation not only in crystals and isolated grains but in ingots and in every article manufactured of iron, steel or any other metal or alloy."[6]

Creating a New Industry

Prodigious Wood Waste Will Be Made Available for Industry by a New Process

AT THE present time, it is safe to say, not much over 40 per cent of the average timber tree gets into the shape of lumber at the mill. The waste of limbs, of unused portions of the trunk, of bark, of sawdust, of slabs and trimmings at the mills make up nearly 60 per cent of the total timber volume. Of course some of this material is burned to fairly good advantage and not infrequently some of it is available for paper making, but from the 30,000 sawmills in the United States the total loss from waste wood must be prodigious, so it is with considerable interest, from both the economic and the technical standpoint, that the recent announcement of the National Lumber Manufacturers Association has been welcomed. Two men on the Pacific coast, W. T. Dumbleton and W. A. Leuenberger, have developed a process for utilizing this wood waste in the form of briquet that will have a thermal value equal to that of the best anthracite coal.

WHAT THE SAVING MAY MEAN

The mill waste which may be used in this new development may amount in value to as much as 50 per cent of that of the large mills. In a fair-sized sawmill, producing 200,000 b.ft. of lumber per day, there will be 200 cords of waste material to dispose of. It is a wicked economic fact that more than half of this material is probably burned in waste burners because there is no market for its utilization. From such a mill the men referred to have produced over 60 tons of charcoal briquet at a manufacturing cost of $8 per ton, nothing being allowed for the cost of the material when the briquetting plant is operated in conjunction with the mill. In addition to this, 15 gal. of tar oil, 30,000 cu.ft. of wood gas and 7 gal. of acetone are recovered for each ton of briquet delivered. With that method of making briquets, it is entirely possible that they will find a use in the metallurgical industries on the Pacific coast, where they would be able to replace high-grade coals at roughly $15 per ton. If such a thing works out economically, it will undoubtedly prove a big boom to the industrial Northwest, where steel and pig iron have not been able to develop because of lack of good coking coal.

POSSIBILITIES OF THE PLAN

From an economic standpoint, the saving is conceivably stupendous. The mills in Washington and Oregon produce 9,000,000,000 ft. of lumber a year. If they were all to introduce this new carbonizing and briquetting process, their waste would make 2,700,000 tons of briquets a year, enough to meet the requirements of the section for high-grade domestic fuel as well as prospective metallurgical requirements on a large scale. Applied to the entire amount of the lumber output of the United States, the potential amount of fuel of equal quality to anthracite realized by this process would be close to 10,000,000 tons. The same land that makes briquets can produce acetone, tar oil and gas with some comparatively inexpensive additional pieces of equipment, and this would net roughly 2,500,000 gal. of tar oil, 5,000,000 cu.ft. of gas and 1,000,000 gal. of acetone each year.

In addition to these figures can be added some considerable savings due to the use of logging wastes, which are about as large as those of the mill waste.

Evaluation of Decolorizing Carbons

It Is Contended That Present Empirical Methods Should Be Replaced by General Adsorption Data

BY MARSHALL T. SANDERS
Atlas Powder Co., Wilmington, Del.

ALTHOUGH decolorizing carbons have been of commercial importance for a decade or two, there is as yet no standard method for evaluating them. Each manufacturer and each buyer has his own test. One selects bone black or some carbon as a standard, and, more or less arbitrarily, says that his product is, perhaps, thirty times as efficient; another rates his product on its "decolorizing power," a test dependent upon percentage of color removed by a given quantity of carbon from a certain solution. A third tries to measure the amount of dye which he can add to an aqueous suspension of the carbon without coloring the water. In all of these methods lies a common fallacy. A straight line cannot be determined by one point, nor is one equation with two unknowns capable of definite solution. It has been shown that decolorization is an adsorption phenomenon. The empirical adsorption equation most widely used in relation to experimental data dealing with adsorption is that proposed by Freundlich:

$$\frac{X}{M} = kC^{\frac{1}{n}}$$

where X is the amount of solute adsorbed by M grams of the absorbent and C is the concentration of this material remaining in the solution at equilibrium. Both k and n are empirical constants and any method of evaluating decolorizing carbons must take into consideration the fact that there are two of them.

METHODS OF MEASURING COLOR

The evaluation of decolorizing carbons postulates the measurement of color, so it might be well to consider immediately the commercially used methods for measuring color of liquids.

There are three of these methods:

(1) The use of Nessler tubes or a Duboscq type of colorimeter.

(2) The use of instruments in which the color of the liquid is matched with tinted glasses.

(3) The use of instruments depending on the measurement of the extinction coefficient for certain wave lengths of light.

Nessler tubes or the Duboscq colorimeter are used only when the colors of the unknown and known samples can be perfectly matched by the dilution of one of them. If several coloring matters are present and are not in the same proportions in both samples, the tints will be different, and a match of the colors practically impossible. L. W. Parsons and R. E. Wilson[1] have found that a Duboscq colorimeter may be used for the measuring of the color of certain oils. In our work with sugars, however, we have found that the color of the decolorized solution cannot be matched with any dilution of the original sample. In such a case, either Nessler tubes or Duboscq colorimeter are useless.

The Lovibond tintometer is an example of the second class of instruments. The chief drawbacks of these instruments are the large assortment of colored glasses necessary, the rather long time consumed in taking a reading, the difficulty of checking results and of two operators reading a given solution alike. Parsons and Wilson in the article referred to above also point out that the Lovibond color scale is not directly proportional to the true color scale. This may be due in part to the loss of light by reflection from the many surfaces exposed when a number of colored slides are used.

In the third class fall spectrophotometers, and possibly the Hess-Ives tintphotometer. A spectrophotometer would doubtless be far better than the Hess-Ives tintphotometer, but the original cost and the care needed for its operation disqualify it for ordinary laboratory work. The color screens of the Hess-Ives tintphotometer transmit rather wide regions of spectrum. However, we have found it quite satisfactory in our type of work.

MODIFIED UNITS FOR HESS-IVES INSTRUMENT

Meade and Harris[2] propose a system of units for use with the Hess-Ives tintphotometer. These units are based on the extinction coefficient. Meade and Harris give equal weight to the units representing red, green and blue violet light. The units which we use are those of Meade and Harris, weighted by the luminosity of each color. A system of these units is given in Table I.

The writer believes these modified units more closely represent the color of a solution as it affects the human eye than do those of Meade and Harris. The scale read-

[1] *J. Ind. Eng. Chem.*, vol. 14, p. 269 (1922).

[2] *J. Ind. Eng. Chem.*, vol. 12, p. 687 (1920).

ing of the Hess-Ives tintphotometer for each screen is translated to "units of color" for that screen. The sum of these values for each screen is taken as the color of the solution.

It is the writer's desire to take exception to a recent statement[3] that the color units read by viewing a ½-in. layer of liquid are not twice the value determined by viewing a ¼-in. layer. The law for the absorption of light by a transparent colored liquid is:

$$\frac{I}{I_0} = E^{-kcd}$$

where I is the intensity of the transmitted light

I_0 the intensity of the incident light

E the base of natural logarithms

k a constant

c the concentration of the light-adsorbing substance

d the thickness of the layer of liquid.

It is a well-known fact that if a colored substance suffers change on dilution, this law does not hold rigidly, but there is no evidence to sustain the opinion previously stated. The writer has found in the case of sugar and molasses solutions that when the thickness of the layer of liquid is doubled the "color units" also double.

At the fall meeting of the American Chemical Society in 1921, Dr. F. W. Zerban presented a paper in which he stated that he had found that the removal of color by carbons follows the adsorption equation, and that by using the Meade-Harris color units in place of the concentration terms X and C in the adsorption formula

$$\frac{X}{M} = kC^{\frac{1}{n}}$$

he had obtained straight lines for the plotted relations of the log $\frac{X}{M}$ to log C.

The modified Meade-Harris units, given in Table I, may be used equally as well in place of the concentration terms X and C. When X and C were expressed in these modified Meade-Harris units, the plot of log $\frac{X}{M}$-log C was a straight line in all cases tested by the writer, except for that end of the curve corresponding to very small quantities of carbon and a consequent slight color removal. It is believed that the determination by the Hess-Ives tintphotometer of the color removed and the use of the modified Meade-Harris units will be found a satisfactory method. However, as has been pointed out above, the Duboscq colorimeter may be used with assurance of accurate results in certain special cases.

Conclusions

In view of the fact that the adsorption equation satisfactorily represents the action of a decolorizing carbon in any given case, it seems that the logical way to evaluate decolorizing carbons is by means of the adsorption isotherm. Furthermore, as the constants of the equation (k and n) are for one particular coloring matter and one initial concentration of that coloring matter, the action of the various decolorizing carbons should be determined for the particular solution it is intended to decolorize.

D. C. Henry[4] is of the opinion that the exponent $\frac{1}{n}$ is the ratio of the osmotic work of adsorption to the total work $\frac{RT}{RT + W}$ where W is the non-osmotic work of adsorption. If this is the case $\frac{1}{n}$ will vary with the coloring matter to be removed. There is no apparent reason why the action of the carbon in one case should be of itself any criterion for its action in any other. It is a well-known fact that often a carbon that is more efficient than another in one case is less efficient in another case.[5] Suppose in the decolorization of a given solution by each of two carbons, that the exponents $\frac{1}{n}$ for these carbons are not identical. Then the efficiency of the two carbons will vary with the color of the solution after decolorization.

We are now in a position to see the fallacies of the present methods of comparing decolorizing carbons. To say that one carbon is so many times as efficient as another is valueless. To rate a carbon on its "decolorizing power" or on some arbitrary test with a dye, while it is a step in the right direction, is inconclusive and misleading. The carbon will probably be used on some solution other than the one on which it was standardized. Even if by chance this should not happen, still by these methods only one point on the adsorption isotherm is determined, and the position or direction of the curve remains unknown.

The ultimate method for evaluating decolorizing carbons must take into account two factors. The various carbons do not act similarly on different solutions and the action of decolorizing carbons, being an absorption phenomenon, follows the adsorption equation.

Increase in Copper Metal Exports

According to *Commerce Monthly*, exports of copper from the United States in 1922 showed a gain of 16 per cent over 1921 and were only 11 per cent below the pre-war average. The declines, as compared with 1921, in shipments to Germany and Japan were more than offset by the gains in exports to Italy, France, the United Kingdom and Belgium.

Ninety per cent of the exports in 1922 was in the form of refined copper, in bars and ingots, 7 per cent as copper rods, less than 2 per cent as uninsulated wire and 1 per cent as plates and sheets. Exports of unrefined, old and scrap copper were under 1 per cent.

Copper exported from the United States meets as its chief competitors in the international market the exports from Australia, Japan, Spain and Africa. Chile, Peru, Canada and Mexico likewise export large quantities, but most of their shipments, either because of financial control or for convenience in shipment, are sent to the United States. A large part of this output is refined here. As a refinery requires a large capital investment, the refineries of the United States play a large part in this country's control of the market.

The ease with which copper may be worked led to its use in many household utensils, although in the Western world it has been displaced in this use to some extent by aluminum and enameled steel. In Eastern countries copper and brass are still almost the only materials from which domestic utensils are made, and large quantities of those metals are imported.

Engine Experiments With Oxidized Oils*

BY J. H. JAMES AND F. C. ZEISENHEIM
Department of Chemical Engineering,
Carnegie Institute of Technology, Pittsburgh, Pa

Engine experiments with a fuel made by the catalytic oxidation of kerosene and a fuel of similar character made by the oxidation of gas oil show that the oxidized kerosenes develop approximately the same power as ordinary kerosene, in spite of the fact that their thermal value is one-eighth less. It is believed that there is a better "clean-up" in the combustion of these partly oxidized fuels, which accounts for their efficiency. These oxidized kerosenes show lower detonation tendencies than the straight hydrocarbon fuel. Similar experiments with lower boiling oxidized fuels in an automobile engine gave results which show that the above results hold here as well.

IT WAS pointed out in a previous article[1] that in the catalytic oxidation of petroleum hydrocarbons there is always a portion of the product having a lower boiling range than that of the raw material, and for convenience this was called "oxidized kerosene." As shown by the distillations of the oxidation products used in the experiments described in the present paper, this material always had between 20 and 35 per cent boiling under 200 deg. C., while the upper limit in every case was taken at 300 deg. C.

Further it was noted in the earlier paper that the fuel value of these products was about one-eighth less than that of ordinary petroleum hydrocarbon mixtures boiling within the same range.

Reasoning from the work of other investigators, particularly that which had been done on alcohol, it was believed that these oxidized kerosenes might show desirable properties when used as a fuel in an internal combustion engine. To test out this idea, the experimental runs described here were made, particular attention being paid to the behavior of the engine as to any "knocking" or detonating characteristics of the fuels, as well as to the power developed in each case.

The fuels tested were: (1) Ordinary kerosene (for comparison), (2) oxidized kerosene made by the oxidation treatment of Pennsylvania kerosene and taking the portion boiling up to 300 deg. C., (3) oxidized kerosene made in the same way from high-sulphur Mexican kerosene, (4) oxidized kerosene made by applying the oxidation treatment to Mexican gas oil, and distilling out the portion boiling up to 300 deg. C.

The Engler distillations of the fuels used in the kerosene engine tests and the later automobile tests are given in Table I.

STATIONARY ENGINE AND AUTOMOBILE TESTS

The kerosene engine used in the first set of experiments summarized in Table II was a one-cylinder, 10-hp., 375-r.p.m., Mogul No. H507, made by the International Harvester Co., of Chicago, and kept in somewhat intermittent use for instructional purposes in the Automotive Laboratory of the Carnegie Institute of Technology. This engine is provided with attachments for "warming up" on gasoline. Lubrication is by forced feed. The water injection is provided for lessening the detonation common with kerosene engines and the readings of this adjustment bring out an important characteristic of the oxidized kerosenes.

Table II gives the more important readings taken; in every case the engine was warmed up by running on gasoline.

Additional experiments bearing on the same line were tried as follows on the two oxidized fuels within the gasoline range:

The motor fuel No. 1 was tested in a six-cylinder car (28 hp.) which was run for 90 miles under all sorts of city traffic conditions, yielding 20 miles per gallon, under the same conditions which gave with ordinary "58-60" gasoline 14 to 15 miles per gallon. The most marked feature of the test was the freedom from detonation with spark advanced and on hills, where the "58-60" fuel gave persistent knocking.

DISCUSSION OF RESULTS

The No. 2 fuel was used in a touring test in the same car with the following results:

Lighter gasoline was needed for priming the cold engine. The road-touring test consumed 10.8 gal. of the fuel, giving an average of 16.5 miles per gallon.

*A paper presented at the Richmond meeting of the American Institute of Chemical Engineers, Dec. 8, 1922.
[1] "Some New Petroleum Products" by J. H. James, *Chem. & Met.*, vol. 26, No. 5, pp. 209-12 (1922).

With spark advanced almost no detonation was observed at any stage of the run. Similar tests with "58-60" gasoline gave about the same mileage, but noticeable detonation.

Realizing that part of the foregoing results on the oxidized kerosene were obtained because of the presence of the fraction boiling below 200 deg. C., it should be pointed out that this portion does not have the ordinary gasoline distillation curve by any means; hence, if we call the portion from 200 to 300 deg. C. kerosene, the under 200 deg. portion resembles, as far as its distillation goes, a heavy naphtha. Looked at in this light, these oxidized fuels up to 300 deg. C. might be regarded as mixtures of ordinary kerosene with heavy naphtha, in ratios from 4:1 to 2:1.

As bearing on this point, an engine run was made

TABLE II RESULTS OF ENGINE EXPERIMENTS WITH VARIOUS OXIDIZED FUELS

Reading No.	Time	Rpm.	Brake Hp	Fuel Weight Lb	Fuel Used Between Readings	Fuel Used Per Bhp-Hr	Temperatures (Deg. C.) Cooling Water In	Cooling Water Out	Air Heater	Exhaust	Fuel Adj	Water Adj	Remarks

with the oxidized Mexican kerosene in the automotive laboratory of one of the large oil companies. The behavior of this fuel as to detonation was checked against a kerosene-gasoline mixture that would give the same low detonation characteristics. It was found that a mixture of 60 per cent kerosene and 40 per cent gasoline was required to bring ordinary kerosene down to that of the oxidized kerosene in low detonating character.

When we note that all the oxidized fuels tried in the kerosene engine have one-eighth lower thermal values than ordinary hydrocarbons within the same distillation range and still gave as good or better efficiencies than ordinary kerosene, the writers believe that we must look to the chemical character of the mixtures for the explanation. According to this idea the original hydrocarbon molecules are weakened toward the oxidation attack in the internal combustion engine because of their oxidized character, so that a better "clean up" results, and perhaps more of a propulsive effect during the explosion which is evidenced by a diminution of the detonation.

Gum Formation With Oxidized Fuels

In the discussion following the presentation of Professor James' paper at the Richmond meeting, Wilbert J. Huff, of the Koppers Co., asked the author if he has noticed any gum formation in the use of this fuel. It was pointed out by the inquirer that gum formation is a very fundamental question in the use of fuels in internal combustion engines and that an investigation by the Bureau of Mines had shown that oxidized gasoline gives a heavy yield of gums. Professor James declared that most of the gum is in the fraction over 300 deg. C. As bearing on the gum formation problem, the oxidation product fractions over 300 deg. C. were made into a lubricating oil by careful vacuum distillation and were used in the same kerosene engine described in the previous tests. There was no varnish-like formation with this lubricant, and the carbon formed was only about half that formed from the well-known commercial engine oil lubricants. This carbon was of a light, fluffy character. Professor James believes that here again the chemical character of the oil is the determining factor in the cleaner combustion.

What Real Co-operation Can Do for the Edible Oil Industry

Manufacturers' Nearsighted Policy of Secrecy Declared a Serious Obstacle to Technical Progress*

BY JOHN P. HARRIS
Chemical Engineer, Kansas City, Mo

OF COURSE we all hate to admit it, but, if we are honest with ourselves, we must acknowledge that the art of edible oil refining has progressed less since its inception than any other branch of applied chemistry. However, we are not willing to admit that this is due to any inferiority of the technical men engaged in this industry, but rather because practically all of the edible oil manufacturers have made a great fetish of secrecy, even introducing this pernicious practice into their own organizations, so that only the chosen few shall know the "wonderful secrets" by which their efficienecy is obtained, with the idea of keeping their quality high above their competitors'. In view of this selfish and near-sighted policy, it is really rather remarkable that the industry has progressed as far as it has. We can readily understand the manufacturers' viewpoint, their idea being to stifle competition and obtain a virtual monopoly upon that business, or at least secure a preference by the discriminating trade.

EXCHANGING TECHNICAL INFORMATION

A few years of real co-operation would make a tremendous difference in the edible oil industry. A few years of pulling together and "speaking out in meeting" would mean a great deal to everyone. The power of suggestion is a wonderful thing and when Jones of the John Doe Co. suggests to Smith of the Richard Roe Co. that we are doing thus and so in our neutralizing process, Smith tries it out, adds his own individual ideas to it and obtains even better results than Jones. He then tells Jones about it, and Jones tries out Smith's suggestions, which he improves by adding some new ideas of his own, and so on ad infinitum. The entire industry becomes stimulated, and undreamed of improvements and economies result.

Would it not be wonderful if we could attend a convention where no one attempted to secure all the information possible from everyone else, at the same time withholding all of his own information and intentionally deceiving everyone else, with the result that no one profits by attending the convention?

Of course we must realize that no firm is ever going to be broad gage enough to sacrifice profits for the uplifting of the industry, but what we do insist is that the sort of co-operation we have mentioned, which sounds like the coming of the millennium, would be of benefit to everyone in the long run, and that the most efficient concerns and those who do the greatest amount of advertising would be the ones to profit most.

Many employers of laborers condemn labor unions because they do not help raise the standard of labor. And yet those very men belong to trade organizations possessed of wonderful potential possibilities for the advancement of their industries, which have never made one single move for the production of higher quality products by that industry.

And the vegetable oil industry is no exception. There is not one concern in the industry which is producing the very best product of which it is capable, even though a part of its product may be very superior. And many concerns, through ignorance or through a near-sighted policy of "getting by" with the least possible cost, are producing a product which is so poor that it is consumed only by the lowest class of trade and forever prejudices the discriminating trade against vegetable oil products, if they happen to try using it.

This condition of affairs cannot be changed without a stiff battle, but could be overcome by the Interstate Cottonseed Crushers' Association and the American Oil Chemists Society if they would inaugurate a *real* campaign for co-operation with deeds instead of words. Those who err through ignorance should be assisted, and those who err through greed should be enlightened and shown that the best way is always the cheapest way.

*Extracts from an article in *The Cotton Oil Press*, official organ of Interstate Cottonseed Crushers Association and the American Oil Chemists Society.

Loading Limestone

Bureau of Mines Issues Paper of Interest to All Plants Utilizing Limestone

IN PLANTS which utilize limestone the removal of fragments of broken rock from the quarry floor and the placing of these in cars for transportation to the kilns is a very important process. At most plants of this nature, the loading constitutes the largest single item in quarry cost. In view of the great expense involved, the Bureau of Mines has made an investigation of the subject and has published the results of this investigation in a paper entitled (Serial 2446) "Rock Loading at Lime-Plant Quarries."

HAND LOADING

Hand loading is prevalent at most lime quarries today, and this method has numerous advantages. The greatest of these advantages, which applies particularly to the small operator, is the necessity involved with a mechanical-loading system for the investment of a large amount of capital, against which the hand-loading system involves very little outlay. Another advantage of the hand system is that a certain amount of sorting of the material occurs as it is loaded by hand. In addition, by hand loading the fines are sorted out to the maximum amount in the first place, so that only large lumps are shipped to the kiln. A final advantage of the hand-loading system is that it eliminates the possibility of breakdown inherent in all mechanical systems.

This hand-loading method, however, has many disadvantages, two of which only need be mentioned. The first is the fact that with the hand-loading system a much larger gang of laborers is necessary and all the troubles which follow on the employment of a large quantity of unskilled labor will attend the operation. The second disadvantage is the fact that the removal of waste and dirt will lag behind the removal of good stone inevitably where the hand-loading system is used, so that extra labor must be employed to remove this waste in proportion to that used for the limestone, and it will be found that the cost runs 2 or 3 cents per ton greater for handling the waste than for handling the good stone. This is not the case with the mechanical method.

LOADING WITH A STEAM SHOVEL

A steam shovel is used in loading limestone in connection with a crushing and scraping equipment, all of which involves a rather high first cost. The extent of the operation should govern the size of the shovel used —for an output of 150 to 300 tons of rock per day the small tractor shovels with ¾ to 1¼-yd. dippers are suitable. The size of the shovel should be increased from there on in accordance to the size of the operation.

A steam shovel has numerous advantages over the hand method of loading. In the first place, it can handle much larger sizes of material, doing away with a great deal of secondary blasting. Second, a great reduction is made in the size of the labor gang necessary. The Bureau of Mines figures show that one man in a hand shovel gang can load only about one-seventh of the material that a man can load with a steam shovel gang. This is, in fact, the principal advantage of the steam shovel and one that can hardly be overestimated.

The first and main disadvantage of the steam shovel method is the fact that it entails the addition of crushing and sorting material, which is quite expensive. A second disadvantage is the fact that it is hard to make any differentiation in quality of the material loaded, as the steam shovel will load any undesirable material just the same as the good rock. This tends to degrade the final product.

In view of the extra cost involved in the use of a steam shovel, for small plants it is sometimes not well to go into these methods, but it is more economical to retain the hand-loading method.

Mineral Production in Canada in 1922

Canada's mineral production in 1922 was valued at $183,000,000—an increase of $11,106,000 over the value recorded in the preceding year, according to a report issued by the Dominion Bureau of Statistics. This amount was made up as follows: Metallics, $61,000,000; non-metallics, $82,500,000; structural materials and clay products, $39,300,000,

The outstanding feature of the metal production was the large increase in gold in both Ontario and British Columbia, amounting to more than 1,230,985 oz. This represents an increase of 31.0 per cent over 1921. Although nickel and copper were lower last year than in 1921, silver and lead increased appreciably both in quantity and value. The end of the year also saw a marked revival in zinc and cobalt. Metals as a whole advanced 23.9 per cent, to a total value of $61,144,990, as compared with $49,343,232 in 1921.

The slight decline in the production of non-metallics, including coal, amounted to approximately $5,260,343 in value. Since the greater part of this decrease was due to loss of production, caused by labor troubles, it may be regarded as negligible. In the successful marketing of structural materials and clay products, the revival of the building industry has played an important part and during the past year production increased.

The output of natural gas from Canadian fields in 1922 amounted to about 14,954,097,000 cu.ft., valued at $5,468,963. The quantity of gas produced was more than 800,000,000 cu.ft. above the output in the preceding year, and the value in 1922 was about $874,799 more.

The output of asbestos in 1922 reached a total of approximately 136,657 tons of all grades, valued at $4,664,106, as compared with 92,761 tons, valued at $4,906,230 in 1921. The appreciable percentage increase in production was due almost entirely to the activity about the mines during the closing months of the year.

The recovery in mineral production as a whole to a total value of $183,029,595 may be considered most propitious. Comparison with preceding years shows that 1920, 1919 and 1917 were the only years in which this valuation was exceeded.

Factors Affecting Contraction of Alloys

The United States Bureau of Mines lists the following as the most important factors affecting the contraction of a non-ferrous alloy on casting: (1) Chemical composition of the alloy; (2) pouring temperature; (3) cross-section of the bar poured; (4) length of the bar in relation to its cross-section; (5) character of the mold, and the method of molding; (6) gas occlusion, and overheating of the melt. These factors are discussed briefly in Serial 2410, "Contraction and Shrinkage of Non-Ferrous Alloys as Related to Casting Practice," which may be obtained from the Bureau of Mines, Washington, D. C.

The Determination of the Specific Gravity of Coke

Method for Finding Real and Apparent Specific Gravities of Coke and From These Values the Percentage Porosity

BY W. A. SELVIG AND W. L. PARKER
Assistant Analytical Chemist and Junior Organic Chemist, respectively, Pittsburgh Experiment Station, U. S. Bureau of Mines

THE percentage by volume of cell-space of lump coke is usually referred to as porosity. In practice, this is calculated from the true specific gravity of the moisture-free pulverized coke and the apparent specific gravity of the moisture-free lump coke, as follows:

Percentage by volume of coke substance

$$= 100 \times \frac{\textit{Apparent specific gravity}}{\textit{True specific gravity}}$$

Percentage by volume of cell-space

$$= 100 - \textit{percentage by volume of coke substance}$$

The experiments here described were undertaken in order to develop a satisfactory method for determining true and apparent specific gravities of metallurgical coke. The methods used by various laboratories for making such determinations differ considerably, and results obtained on the same sample may vary decidedly depending on the methods used.

TRUE SPECIFIC GRAVITY

The true specific gravity is, as a rule, determined by boiling the pulverized coke in a liquid, usually water, in an accurately calibrated pycnometer, so as to wet the coke particles thoroughly and displace included gases.

Experiments were made as to the effects of fineness of grinding, the medium used, and the time and method of boiling. The pycnometer used was the Hogarth specific gravity bottle, which usually has a capacity of 100 to 125 cc. and is convenient to manipulate. Each bottle was accurately calibrated, and a table was constructed giving capacities in grams of water at a range of room temperatures likely to exist in the laboratory. The true specific gravity was calculated by the use of the following formula:

$$\textit{True specific gravity} = \frac{W}{W - (W' - P)}$$

when W = weight in grams of dry coke
W' = weight in grams of pycnometer + coke + water
P = weight in grams of pycnometer + water.

EFFECT OF TIME OF BOILING AND PARTIAL VACUUM

Two samples of metallurgical coke, pulverized in ball mills to pass a 60-mesh sieve, were selected. One was a 72-hour beehive foundry coke, Connellsville, Pa., region; and the other was a byproduct coke from Franklin County, Ill., coal.

Ten grams of moisture-free coke was boiled in water at atmospheric pressure for periods ranging from ½ to 3 hours; other samples were boiled at atmospheric pressure for a half-hour, and the boiling continued for another half-hour under the partial vacuum of a Chapman water filter pump; while samples were also boiled on a water bath under partial vacuum for 3 hours. The results of these tests are given in Table I.

It will be noted from the table that the same results were obtained by boiling at atmospheric pressure for ½- or 1-hour periods as by boiling for 3 hours; also, no noticeable difference resulted when the boiling was performed under a partial vacuum. These results indicate that boiling the pulverized coke for 1 hour at atmospheric pressure is as satisfactory as boiling for longer periods or boiling under a partial vacuum.

EFFECT OF FINENESS OF SAMPLE AND LIQUID MEDIUM

Two samples of byproduct coke, one of beehive coke and one of low-temperature coke made in the laboratory at a temperature of 500 to 600 deg. C., were pulverized in ball mills until one portion passed a 60-mesh sieve and another portion a 200-mesh sieve. Specific gravity determinations were made on the 60- and 200-mesh samples, using both water and benzene as mediums. The specific gravity determinations in water were made by boiling for 1 hour at atmospheric pressure, and

TABLE I—EFFECT OF TIME AND METHOD OF BOILING 60-MESH COKE IN WATER

Time and Method of Boiling	True Specific Gravity	
	72-Hr. Beehive Foundry Coke, Connellsville Region	Byproduct Coke From Illinois Coal

	Average	1.93	1.96	1.96	1.96
Byproduct coke from Illinois coal	(Ash in dry coke, 14.0 per cent) / (Ash in dry coke, 14.1 per cent)	1.851	1.793	1.920	1.806
		1.845	1.803	1.919	1.803
		1.845		1.919	
	Average	1.85	1.80	1.92	1.80
Byproduct coke from Pittsburgh bed coal	(Ash in dry coke, 10.6 per cent) / (Ash in dry coke, 10.7 per cent)	1.860	1.832	1.882	1.842
		1.864	1.838	1.890	1.842
		1.86[illegible]		1.885	
	Average	1.86	1.84	1.89	1.84
Low-temperature coke (500-600°C.) from Pittsburgh bed coal	(Ash in dry coke, 4.0 per cent) / (Ash in dry coke, 4.1 per cent)	1.517	1.469	1.525	1.550
		1.524	1.468	1.528	1.554
		1.520		1.526	
	Average	1.52	1.47	1.53	1.55

those in benzene by boiling a half-hour at atmospheric pressure. Ash was determined on the 60- and 200-mesh portions in order to ascertain whether any increase of ash resulted from the longer grinding required to pass the coke through 200-mesh sieves. The results of these tests are given in Table II. Sizing tests made on the through 60-mesh samples of the four cokes to determine the approximate fineness of the samples showed:

Mesh	Connellsville 72-Hr Beehive Foundry Coke, Per Cent	Byproduct Coke From Illinois Coal, Per Cent	Byproduct Coke From Pittsburgh Bed Coal, Per Cent	Low-Temperature Coke From Pittsburgh Bed Coal, Per Cent
On 100	34.9	1.6	23.7	24.2
Through 100, on 200	36.3	50.2	41.8	44.0
Through 200	28.8	48.2	34.5	31.8

It is noted from Table II that there is considerable difference between the results obtained with water and those with benzene. In most determinations benzene gave lower values than water, but in some the reverse was true. With benzene all of the metallurgical cokes gave the same results on 60- or 200-mesh samples; however, for the low-temperature laboratory coke, the 200-mesh sample gave the higher specific gravity. With water, all of the cokes gave a higher specific gravity on the 200-mesh samples, the greatest difference being for the byproduct coke from Illinois coal, where it was higher by 0.07 than for the 60-mesh material. The slight increase in ash content of the 200-mesh material, due to longer grinding, was so small that it did not affect the specific gravity of the samples.

Rose[1] made similar true specific gravity tests on a number of cokes, using water and benzene as mediums, and found in each test that the results obtained with benzene were lower than those with water, these differences ranging from 0.025 to 0.150. He also determined the specific gravities in benzene of portions of a byproduct coke, the one portion being pulverized to pass 60 mesh and the other to pass 200 mesh, and obtained a value higher by 0.06 on the 200-mesh material.

[1]Rose, Harold. J., "The Determination of the True Specific Gravity of Coke," *J. Ind. Eng. Chem.*, vol. 14, No. 11, 1922, pp. 1047-1049

There is no apparent reason why water should not be used as the medium in determining true specific gravity of pulverized coke. Other mediums may or may not give results comparable to those obtained with water, and benzene evidently will give results differing from those obtained with water.

The higher results obtained with water on the 200-mesh material, as compared with those obtained on the 60-mesh material indicate that it is desirable to pulverize the coke to pass a 200-mesh sieve for true specific gravity determinations. The greatest difference observed was in the byproduct coke from Illinois coal, where a value of 1.85 was obtained on the 60-mesh material, compared to 1.92 on the 200-mesh material. Assuming an apparent specific gravity of 0.90, this difference would amount to 2 per cent in calculating the percentage by volume of cell-space in the lump coke.

Method for True Specific Gravity

Hogarth's specific gravity bottle with a side tubulure is a convenient type of pycnometer for the determination. This bottle as furnished usually has a capacity of about 125 cc. The bottle should be accurately calibrated, and a table constructed giving its contents in grams of water at room temperature likely to occur in the laboratory. This is readily done from tables prepared by the Bureau of Standards[2] giving corrections for determining the true capacities of glass vessels from the weight of water in air.

A 10-gram portion (W) of 200-mesh coke, which has previously been dried for an hour at 105 deg. C., is carefully introduced into the weighed specific gravity bottle with enough distilled water to fill it about half full. It is then placed on a hot plate, and kept boiling for an hour, with frequent shakings to wash down any coke adhering to the sides. It is then removed from the hot plate, filled to the tubulure with recently boiled and cooled distilled water, the stopper inserted, and permitted to cool to room temperature. (Cooling may be hastened by placing the bottle in water.) Next, the bottle is filled to slightly above the mark on the capillary of the stopper. This is conveniently done by inserting the end of the tubulure in a small beaker of previously boiled distilled water, which has been cooled to room temperature, and applying a slight suction on the stopper. The water level is adjusted to the mark on the capillary by touching a piece of filter paper to the end of the tubulure. The bottle is then wiped dry and weighed (W'). Immediately after weighing, the stopper is removed, and the temperature of the contents taken. The capacity of the bottle in grams of water at the temperature recorded is obtained by reference to the calibration table of the bottle (P).

The true specific gravity is conveniently calculated by the following formula:

$$\textit{True specific gravity} = \frac{W}{W - (W' - P)}$$

in which

W = Weight in grams of dry coke.

W' = Weight in grams of bottle + dry coke + water to fill.

P = Weight in grams of bottle + water to fill.

Apparent Specific Gravity of Lump Coke

The apparent specific gravity of lump coke is determined in practice by immersing the coke pieces in water, and determining the amount of water displaced.

[2]"Standard Density and Volumetric Tables," Bureau of Standards Circular 19, 1916, pp. 52-56.

As lump coke is a cellular substance, considerable water may penetrate into the coke pieces, so some experiments were made as to the amount of this, and attempts were made to determine the apparent specific gravity by preventing any water from entering during the determination.

The apparent specific gravity tests were made with a Nicholson hydrometer, which instrument permits weighing the sample in air and also when totally immersed in water. The capacity of the hydrometer used was approximately 500 grams of coke. Pieces of coke about 1½ to 2 in. in size were used.

Three byproduct cokes were available for the tests. The samples were dried to constant weight at a temperature of approximately 150 deg. C. previous to making the determinations. About 500-gram samples were taken and weighed in air, after which they were immersed in water for about 3 minutes, and the weight of the sample in water determined. The coke pieces were then removed from the water and allowed to drain for about 1 minute, and then were weighed in air again to determine the weight of water absorbed. The same pieces of coke were then re-dried to constant weight at 150 deg. C., and coated by painting with melted paraffine. Apparent specific gravity determinations were made on the paraffined coke pieces, and a correction was made for the coating of paraffine—the results thus obtained were regarded as the correct apparent specific gravity of the coke.

After immersion of the paraffined pieces, all surface water adhering to the paraffine was removed by absorbent paper, and the pieces were weighed in air to determine the amount, if any, of water that might have penetrated into the coke. The apparent specific gravities of the cokes as determined (1) without correcting for absorbed water, (2) correcting for absorbed water, and (3) as determined on the paraffined pieces, are given in Table III.

TABLE III—APPARENT SPECIFIC GRAVITY OF COKES
(1) Not corrected for absorbed water (2) Corrected for absorbed water, and (3) As determined on paraffined coke

Condition	Apparent Specific Gravity		
	Coke No. 1 Weight of sample 413 grams	Coke No. 2 Weight of sample 407.5 grams	Coke No. 3 Weight of sample 488 grams
No correction for absorbed water	1.16	0.98	1.09
Correcting for absorbed water	1.03 44 grams water absorbed	0.91 30 grams water absorbed	1.00 39.6 grams water absorbed
Determined on paraffined coke and correction made for paraffine	1.05	0.94	1.02
Correcting for water absorbed by paraffined coke	1.04 5.5 grams water absorbed	0.93 4 grams water absorbed	1.00 10.8 grams water absorbed

The tests show that considerable water was absorbed by the coke during the 3-minute immersion in water, the amount varying from 7 to 10 per cent of the weight of coke. It is evident that unless a correction is made for the water absorbed, a considerable error will be introduced. The absorption of water by the dry coke proceeds rapidly after immersion. Coke No. 3, after immersion for 3 minutes, was weighed in air and re-immersed for 30 minutes. It was found that 39.6 grams of water was absorbed in 3 minutes and 46.5 grams in 30 minutes; however, when a correction was applied for the water absorbed, the apparent specific gravity was the same (within experimental error), being 1.00 after the 3-minute period and 1.01 after the 30-minute period.

The paraffined pieces of coke absorbed a small amount of water during the 3-minute period of immersion, the amount ranging from 5 to 10 grams. As the paraffined coke pieces were dried with absorbent paper after immersion, this small gain in weight may be accounted for by imperfections in the paraffine coating on the coke pieces, which probably allowed some water to get into them. Assuming that this small amount of water was absorbed, and making the slight corrections for it, the values obtained for apparent specific gravity are in close agreement with those obtained in the usual manner when a correction is made for absorbed water. The maximum difference between the values obtained for the paraffined coke and those for unparaffined coke after correction for absorbed water amounted to only 0.02. It will be noted that if a correction is not made for the large amount of absorbed water when determining apparent specific gravity in the usual manner, the values obtained will be considerably higher than if the correction is applied—the differences in the three cokes listed in the table ranging from 0.07 to 0.13. It is evident that such a correction should be made in any method for apparent specific gravity which permits water to be absorbed by the sample during immersion.

METHOD FOR LARGE PIECES OF COKE

The cell structure of coke pieces from the same oven or retort usually shows noticeable variation, and the cell structure of the same piece of coke may vary at different points of the piece. If a small sample of coke is used for apparent specific gravity determinations, it is essential to select the sample carefully so as to be representative of the coke. The Nicholson hydrometer used in the tests described had a capacity of about 500 grams. By careful selection of the portions for duplicate tests, good checks on duplicate determinations can be obtained with the Nicholson hydrometer method. The sample should be in the form of pieces about 1½ to 2 in. in size, and the pieces used for the tests must be systematically selected. Of 170 different cokes on which duplicate apparent specific gravity determinations were made, the average difference between duplicate determinations was 0.03.

A method by which a large sample of large pieces could be used would be desirable, as it would be easier to select a representative sample. Such a method has been used by the Koppers Co., and the method is one of those for the apparent specific gravity of coke adopted by the American Gas Association.[4] The method is as follows: Select 25 to 30 lb. of coke, which should be as nearly representative as possible of the entire quantity under consideration with regard to size, shape and general appearance. Dry the coke thoroughly at 105 to 200 deg. C., and weigh when cool after shaking and brushing off any adhering dust (*A*).

Provide a wash-boiler or other suitable container with a spout, which may be conveniently formed by soldering in horizontally a short ½-in. nipple about 2½ in. below the top of boiler. The boiler should be placed on a level and rigid base or floor. A wire cage or basket provided with a cover and a long wire handle suitable for holding the entire sample of coke should also be provided and placed in the boiler.

Place a tightly fitting cork in the ½-in. nipple and fill boiler with water until the water level is above the nipple. Allow the water to come to rest, remove cork,

[4] "Gas Chemists' Hand Book," American Gas Assn., 1922 edition, pp. 58-59.

permit all excess water to drain, and replace cork. Remove cage, shaking all adhering water back into the boiler and place the dried coke sample in the cage. Lower the cage and coke into the water and let stand for 30 minutes, with occasional stirring of coke to detach any air bubbles adhering to the surface of the coke, but without disturbing the position of the boiler. The coke must be completely submerged at all times. At the end of the 30 minutes, after the water has come to rest, remove cork and allow the displaced water to drain into a weighed container. Weigh the displaced water (B). Quickly remove the cage and coke from the water, allow to drain for 1 minute and weigh wet coke without cage (C).

A = Weight of dry coke.
B = Weight of water displaced by wet coke.
C = Weight of wet coke.
$C—A$ = Weight of water absorbed by coke.
$B + (C—A)$ = Weight of total water displaced and absorbed.

$$\frac{A}{B + (C - A)} = \text{Apparent specific gravity.}$$

(Note: The water should be near room temperature so as not to vary appreciably.)

Results of This Method

As will be noted, the above method uses a large sample of coke, and makes a correction for water absorbed by the coke during immersion, which, according to the experiments previously described in this paper, should give fairly correct values for the apparent specific gravity of coke.

In order to test the accuracy of the method, tests were made on two different byproduct cokes which were available in sufficient quantity to obtain approximately 18 lb. of large-size pieces. A wash-boiler was used as the water container. The coke pieces were dried to constant weight at about 150 deg. C. before the determinations. The same pieces of coke were used throughout the tests, all water being removed before each determination by drying to constant weight. The results of these check determinations are given below:

Apparent Specific Gravity Check Results as Determined on Same Pieces of Coke by Method Using Large Sample

	Coke No. 1 (8400-gram sample)	Coke No. 2 (8050-gram sample)
	0 91	1 05
	0 90	1 04
	0 90	
Average	0 90	1 05

The results show that the method itself is accurate inasmuch as, obtaining close checks, the greatest difference shown was only 0.01.

It was found, when the cork was removed from the overflow spout in order to allow the water in the wash-boiler to come to a constant level, that water would drip from the spout for a long time. Satisfactory results were obtained by allowing the water to drip for 1 minute after the overflow stream started to discharge drop by drop.

Conclusions

For calculating the percentage by volume of cell-space of metallurgical coke, the following conclusions are drawn from the tests on methods of determining true and apparent specific gravities:

1. True specific gravity may be satisfactorily determined by boiling the pulverized coke in water at atmospheric pressure for 1 hour in a convenient calibrated pycnometer such as the Hogarth specific gravity bottle.

2. The experiments indicate that it is not necessary to boil the sample under reduced pressure, or to boil at atmospheric pressure for periods longer than 1 hour.

3. Somewhat higher results were obtained for true specific gravity on coke samples pulverized to pass a 200-mesh sieve as compared to the same samples pulverized to pass a 60-mesh, so it appears to be desirable to pulverize the coke to pass a 200-mesh sieve.

4. It is not advisable to use other mediums besides water for determining true specific gravity of coke, as the results may not be comparable. In the case of benzene, the results obtained did not check those obtained with water, and benzene appears to have a tendency to give lower values than those obtained with water as a medium.

5. In determining the apparent specific gravity of lump coke, a correction should be applied for water absorbed, as metallurgical coke is a cellular substance which absorbs considerable water rapidly after immersion.

6. The method for determining apparent specific gravity, using a sample of 20 to 30 lb. of large pieces of coke, and correcting for the water absorbed, is recommended.

The writers are indebted to A. C. Fieldner, supervising chemist, Pittsburgh Experiment Station, U. S. Bureau of Mines, for helpful suggestions.

Investigation of Mineral Fillers

At the Southern experiment station of the Bureau of Mines, Tuscaloosa, Ala., a special study is being made of the determination of the grain size and character of grains of representative fillers produced in the district. This investigation of non-metallic minerals is for the purpose of determining their use as mineral fillers. It includes a study of the various methods of calculation of average grain size applicable to fillers which vary greatly in size—from diameters of 100 microns or more to zero—and the determination of average grain size of representative samples of commercial fillers, including clay, barite, fullers earth, whiting, mica, ocher, slate, silica and talc. The character and size of particle of fillers is a basic property which has an important effect on the other physical properties and characteristics.

A study of the effect of grain size of fillers in compounding is also being undertaken and will be conducted along the line of determining the difference in actual use between a filler made up of mixed sized grains as usually employed, and the same material classified within as close limits as possible regarding variation in grain size and having the same average diameters as the mixed product. It will also include the determination of the difference in effect between two products of the same material but classified between different limits of grain size.

The effect of heat-treatment on the properties of non-metallic minerals other than clays with respect to their use as fillers is also being studied by the Bureau of Mines. This will involve a determination of the effect of heating at different temperatures on the specific gravity, loss in weight, color, grain size, oil absorption, covering power or spread and ease of grinding. Previous work on clays along the same line has shown an improvement of certain samples for filler use.

The relationship among grain size, oil absorption and covering power of fillers and pigments is also being investigated. The general direction of this relationship is known, but no exact data are available on the subject.

Effect of Ammonia on Steel

In co-operation with the Fixed Nitrogen Research Laboratory, the Bureau of Standards has made a microscopic examination of specimens representing a series of steels varying in carbon content from 0.02 to 0.98 per cent exposed to a current of ammonia at temperatures in the range of 100 to 700 deg. C. The purpose of this test was to determine the effect of change in carbon content upon the method of attack of heated ammonia. No change was observed on the specimens up to 400 deg. C.; at 500 deg. a film of white nitride was followed by the layer of nitride needles. At 600 deg. C. this effect increased, while at 700 deg. a new compound of nitrogen was formed following directly the film of white nitride layer. At 700 deg. C. the nitride needles in low-carbon steels removed further from the edge to the center. They are absent at that temperature in high-carbon steels of 0.49 to 0.98 per cent C.

Testing a Cost System

The rules to apply in analyzing the soundness of a cost system are:

Does your cost system give you up-to-date costs, not merely history?
Does it aid in stablizing your wages and piece work rates?
Does it point out defects in your routing system?
Does it help you maintain a perpetual inventory?
Does it increase your production?
Does it measure your overhead?
Does it detect new overhead expense?
Does it point out leaks in expense?
Does it encourage your employees?
Does it promote intelligent competition?
Does it point to non-profit paying lines?
Does it permit you to bid safely?

Twelve suggestions for testing the value of a cost accounting system are given in a pamphlet issued recently by the fabricated production department of the Chamber of Commerce of the United States.

A cost accounting system is very much like the engine of an automobile, only there are more various kinds of cost systems and their idiosyncracies are legion. If a cost system fails to show what it should, it consumes profits. It pays to check your system; you ought to determine the upkeep and make sure it pays.

Wear Tests on Steels

Some investigations on the wear of steel have been under way at the Bureau of Standards, in connection with the work sponsored by the Gage Steel Committee. Especial effort has recently been made to keep the surfaces of the specimens clean and free from all adhering abraded particles while under test. A cloth buffing wheel, rotated at high speed by electric motor, has been used successfully for this purpose. It has been found that when the wearing surfaces are thus kept free of abraded metallic dust, the rate of wear drops to a comparatively almost negligible quantity.

Record Sugar Crop in Hawaii

Hawaii's sugar cane harvest during the year ended last Sept. 30 was the largest in 8 years, according to an estimate by the Department of Agriculture. Production for the year was placed at 1,184,000,000 lb., or 13 per cent more than that for the previous year

A New Instrument for Testing Glue and Gelatin Jellies

Description of Bloom Gelometer Developed for Factory Control Work, but Useful for Other Jelly Strength Investigations

BY WILLIAM D. RICHARDSON
Chief Chemist, Swift & Co., Chicago

THE jelly strength of glue and gelatin may be considered the most important single determination which it is customary to make on these important substances. Following the old finger test method, which is still in use in many factories in this country and abroad, numerous mechanical devices have been developed for the purpose, all of more or less merit. A description of these is scattered through the literature, and a summary of a number of types, including those of Peter Cooper, Lipowitz, Valenta, Scott, Alexander, E. S. Smith, Forest Products Laboratory, Hulbert, C. R. Smith, Sheppard and Schweitzer, are included in Bogue's[1] recent work on gelatin and glue. In addition to these a number of other types are in use in the laboratories of different glue factories.

The outstanding feature of all previous testing machines for jelly strength is that they have not been standardized and reproducible. Each has been a law unto itself capable of developing comparable results, which were intelligible to the user in terms of certain glue and gelatin standards, the standards being carefuly preserved from month to month and year to year for making comparisons with factory runs and shipments of product. Standards of this sort, however, ultimately became exhausted and when new standards were selected they were probably not identical with the old.

The fundamental idea underlying the development of the Bloom Gelometer, named after O. T. Bloom, its inventor, was that of a machine so constructed that it could be reproduced by measurement and, given precisely regulated conditions, would yield identical results at any time and place on the same sample. It should be understood, however, that due caution be observed in applying the term "precisely regulated conditions," particularly as regards the temperature of the jelly, which must be most carefully controlled and regulated for a definite period of time prior to the test by means of a thermostat bath.

GENERAL DESCRIPTION

This instrument is so designed that the two factors, diameter of plunger and depth of plunge, are maintained constant, and the third factor, time of application of the pressure, which is applied by means of flowing shot, is kept within a reasonably close time limit. While the depth of plunge can be varied, it is kept precisely at 4 mm. for the purpose of testing glue and gelatin jellies, while the time of introduction of the shot is maintained between 2 and 5 seconds. The diameter of the plunger is exactly 12.7 mm. (½ in.) and is constructed of aluminum or hard rubber, the sharp lower edge being rounded to the slightest possible degree to prevent cutting.

The instrument is automatic in its action. Once started by hand, the flow of shot is rapid and continuous between the two contact points, and the cut-off is sharp

[1]"The Chemistry and Technology of Gelatin and Glue," by Robert H. Bogue, Mellon Institute Technochemical Series, McGraw-Hill Book Co., Inc., pp. 369 to 380 (1922).

when the silver disk working between the two contact points reaches the lower point. It has been found in the comparatively brief time that the instrument has been operated that it yields excellent results, accurate beyond the requirements of factory or trade.

In reading the following description and working directions for the instrument, reference should be had to Fig. 1.

The instrument is mounted on the base R_1 and the pillar R_2. The adjustment stand N resting on the base R_1 is provided with a platform N_1 capable of being raised and lowered by the rack and pinion mechanism N_2. Affixed to the upper end of the pillar R_2 by the bracket J_1, the spring adjusting mechanism G holds the spring F and the plunger L, hanger and pan H_1 and H_2 respectively. At the upper part of the plunger hanger, the silver contact disk B is set to operate between the contact points A_1 and A_2. The rod H_3 of the plunger hanger works through the adjustable guide J_{2a} which is affixed to the bracket J_2.

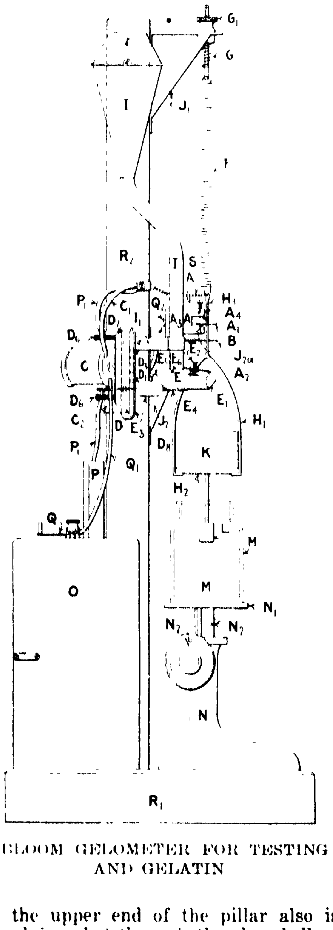

FIG. 1—BLOOM GELOMETER FOR TESTING GLUE AND GELATIN

Affixed to the upper end of the pillar also is the shot hopper I, supplying shot through the clamshell cut-off E-E_1 to the shot receiver K, which rests on the pan H_2. The automatic shot control mechanism D-D_5, working on the clamshell cut-off E-E_1 consists of the electromagnet C, the soft iron bar D_7 carrying the brass dogs D_1 to D_5 and the brass guide bar D.

The cut-off mechanism consists of the clamshell cut-off E-E_1, the control rod E_4, working on the dogs D_1-D_5 and the counterbalance weight E_3. E_2 is the bearing on which the cut-off mechanism turns. The entire cut-off mechanism is adjustable vertically on the pillar R_2 by means of the screws C_2, this adjustment setting and adjusting the pitch of the clamshell cut-off E-E_1. This adjustment is made when the machine is assembled and is permanent.

Electric current is supplied to the electromagnet C through the contact points A_1-A_2 from the 3-volt dry battery O through the connections Q_1, C_1, S and Q_2. P is a small telephone condenser arranged in shunt circuit by means of the connections P_1 and P_2.

The test bottle M containing the jelly to be tested rests on the platform N_1.

The space between contact points A_1 and A_2 is adjusted as follows: With the current cut off by means of switch Q and with the silver disk B resting on contact point A_1, adjustment is made by means of the adjustment screw A_4 so that the distance between the upper face of the silver disk B and the contact point A_1 is exactly determined. This determines the depth of plunge. In the case of glue and gelatin jellies, the depth of plunge is exactly 4 mm. as determined by the standard Brown & Sharpe 4-mm. gage furnished with the instrument.

Adjustment is now made of the silver disk B against contact point A_2 by turning the adjustment screw G_1 (which acts on the spring F) until the silver disk B is in lightest possible contact with contact point A_2. When this point is reached, sparking will be noticed between the point A_2 and the disk B and a make-and-break vibration is set up between the soft iron bar D_7 and the core of the electromagnet C. When this adjustment is once carefully made the machine stays in adjustment for some time, although readjustment should be made occasionally.

The glue or gelatin jelly (or the like), prepared in the usual way or according to standard directions, is placed in the test bottle M and chilled to the test temperature for the desired length of time. The bottle is placed on platform N_1 and raised by means of the rack and pinion mechanism N_2 until the jelly is in contact with the plunger L and the latter is raised until the silver disk B is brought into light electrical contact with contact point A_1. This point is indicated by sparking and make-and-break vibration between the soft iron bar D_7 and the core of the electromagnet C. The shot receiver K is quickly placed on pan H_2 and immediately the lever E_4 is raised to the predetermined position on one of the dogs D_1-D_5. The height to which lever E_4 is raised regulates the velocity of the flow of shot. For weak jellies one of the lower dogs is used, for strong jellies one of the upper dogs. The dog selected should be such as to keep the flow of shot within the prescribed limit of 2 to 5 seconds. The finest chilled shot obtainable is used, No. 12 or finer. The raising of the lever E_4 immediately starts the flow of shot, depressing the plunger L into the jelly until contact is made between the silver disk B and contact point A_2. This closes the circuit which acts on the electromagnet C, moving the soft iron bar D_7 and withdrawing the support of the dog from the lever arm E_4, which immediately falls, thus cutting off the flow of shot by closing the clamshell cut-off E-E_1.

The weight of shot delivered into the shot receiver K plus the weight of the shot receiver itself is the weight required to move the plunger L through the prescribed distance against the resistance of the jelly, and measures the jelly strength. For glues and gelatins this distance is exactly 4 mm. as determined by a Brown & Sharpe gage.

After the combined weight is determined, the shot is emptied back into hopper I and the machine is ready for another test.

The Bloom Gelometer is sufficiently accurate for all control work in glue and gelatin factories and is, in fact, rather more sensitive than previous devices for the same purpose. It can also be applied to the investigation of jellies for scientific purposes and for the determination of the influence of various factors on the strength of jellies, such as concentration, p_H value, time of setting, time of pressure application, etc. It should be used in conjunction with a thermostat bath capable of being regulated to within 1/10 of 1 deg. C. at 10 deg. C., and by preference test should be made in a chill room the temperature of which is carefully controlled at 10 deg. C.

Columnar Crystallization in Ingots of Invar

The Bureau of Standards has studied the ingot structure of ingots of invar (Fe:Ni 65:35) and the relation of the structure to the forgeability of the alloy. It has been found that ingots cast in chilled molds cool too slowly and form excessively large columnar crystals, producing a very brittle ingot which breaks readily on forging. To correct this difficulty a specially designed and refrigerated mold must probably be used.

Synopsis of Recent Chemical & Metallurgical Literature

Ingot Practice for Chromium Steels

In order to find the effect of the rate of solidification on the eutectic network, P. Oberhoffer[1] made six series of chromium steels with carbon varying from 0.65 to 1.50 per cent and chromium from 1.8 to 13.5 per cent. In every series, consisting of two charges each, one was chill cast and the other allowed to cool down with the ladle. On macro-etching, the latter showed a dendritic structure and the former a fine globular structure. On "secondary" etching with a concentrated solution of picric acid in alcohol containing a few drops of nitric acid, the slowly cooled steels showed a large network and chill-cast steels a fine network. Test pieces were then forged down from 45 mm. square to 15 mm. square. On microscopic examination the slowly cooled steels showed long drawn out accumulations of carbide particles, while in the quickly cooled steels the carbides were distributed quite evenly throughout the sections. Mechanical tests indicated that the notch toughness was higher in chill-cast specimens—otherwise the results were quite similar.

Composition of Blast-Furnace Gases

The composition of blast-furnace gas is definite enough to be expressed by a linear formula, as pointed out by M. J. Seigle in *Revue de Métallurgie*, 1922, vol. 19, pp. 11-36. If the respective percentages of nitrogen, oxygen, carbon dioxide, carbon monoxide, hydrogen, water (vapor) and methane are a, b, c, d, e, f and g, so that $a + b + c + d + e + f + g = 100$, then $4.76b + (4.76 - N)c + (2.88 - N)d + 0.88e + f + g = 100$. If the amounts of oxygen (b), of hydrogen (e) and of methane (g) can be left out, then for a dry blast

$$(4.76 - N)c + (2.88 - N)d = 100.$$

In this formula N is a function of the volume of carbon dioxide introduced by the carbonates from the flux (λ), of the volume of oxygen from the oxides in the ore (μ) and of the percentage a of carbon contained in the pig iron, whose total weight is F.

$$N = \frac{\lambda + \mu}{0.495\left(1 - \frac{aF}{100}\right) + 0.54\lambda}$$

It follows from these formulas that the possible values for the volumes c and d of carbon dioxide and carbon monoxide will lie on certain straight lines. These lines are not parallel and the points where they intersect the axes c and d are easily calculated.

Applying these formulas to the extreme case of that of a gas producer, we have $4.76c + 2.88d = 100$.

On the other side, for an electric blast furnace we have the simple equation $a + b = 100$.

This latter line shows the limit for the possible numerical values of CO. and CO. Thus a graphical representation of the composition of blast-furnace gases is conveniently drawn and various theoretical and practical conclusions easily arrived at. Most important is the possibility of predicting the various occurrences which would happen when any changes are introduced in the conditions existing in the blast furnace

Fuel Oils in Internal Combustion Engines

There are three distinct types of difficulties encountered in the burning of heavy oils—namely, ignition, burning after ignition, and impurities. Even an oil that meets two of these requirements is often found unfit for use on account of the third effect. Harold Moore, in a paper which is presented in abstract form in the *Journal of the Franklin Institute* for February, 1923, classifies heavy oil engines in the three groups: Diesel engines using compressed air for firing; cold starting engines which fire by spontaneous combustion, the fuel being pulverized without air blasts; and hot bulb engines in which the fuel is injected mechanically, external heat being applied to insure ignition. The capacity of an engine for burning heavy fuels is not merely dependent upon the cycle and the method of fuel injection; it is also determined to a very marked degree upon the size, speed, compression, fuel-valve tuning and other factors.

Fatigue of Metals

To find out (1) whether a safe "endurance limit" does really exist and (2), what is happening to a metal subjected to alternating stresses, investigations were undertaken by Professor Ludwick[1] at the Technical College in Vienna. Specimens of aluminum, copper and iron were subjected to series of stresses and the results were plotted as curves, having for co-ordinates the unit stress and the number of cycles. The results indicate that even when the number of repetitions becomes infinite, the unit stress necessary for fracture does not approach zero. This means that an endurance limit is passed by metal and that lesser stresses can be applied to the specimen indefinitely.

It has been further found out that the resistance to alternating impact stresses depends not on the ductility or malleability of the metal, but on its elastic limit, its yield point and hardness—in other words, this resistance is not a function of the faculty of the material to endure deformation, but to withstand deformation. For instance, a quenched specimen, in spite of its brittleness, would show a better resistance under these tests than an annealed one

Microscopical investigations show how stresses produce slipping along crystal planes inside the crystallites. If stresses are small such slipping usually

[1]Paper read June 29, 1922, before the German Association for the Study of Metals, and abstracted in *V. D. I. Nachrichten*, 1922, No 28/29a, July 19, pp 310-311

Important Articles in Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature and consequently should be of considerable interest to our readers Those that are of unusual interest will be published later in abstract in this department; but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date

occurs where the metal is less homogeneous—i. e., in the neighborhood of slag enclosures, porosities and impurities. At such places even a certain rise of temperature can be detected, showing that it is there that the metal actually "works"; on the other hand the sound metal would be still subjected to elastic deformations only.

Gas Producers

At a meeting of the Manchester Section of the Society of Chemical Industry, held on Feb. 2, T. R. Wollaston read a paper on "Some Developments in Gas Producers," which was reported in the *Iron and Coal Trades Review* for Feb. 9, 1923.

The results obtained from gas producers of the recovery and non-recovery type are compared with those from an improved plant which has been devised with a view to eliminating as far as possible the faults of the older systems.

Performance

The paper set forth a statement of the average performances of gas producers at the time (10 years ago) when the author began his investigation, and indicated the causes of loss and inefficiency which appeared preventable. These, expressed in B.t.u. and money value and compared with the new plant—the R-G. plant so called—are shown diagrammatically in Fig. 1 and Fig. 2. In Fig. 2 an assumption is made that an ammonia sulphate yield of a gross value of 7s. involves a production cost of 4s.

The R-G Producer

The R-G. experimental plant which gave the records from which these diagrams were made has a 9-ft. diameter producer of 1,300 lb. hourly capacity. The fuel is introduced through a retort in contact with hot exit gases and is thus partly coked, while the gases are enriched. The steam for the process is raised by means of an annular boiler, surrounding the unlined producer body. Blast saturation and superheat are derived from a central cone-shaped boiler within the producer which acts as a flash-boiler.

The author pointed out that the precoking leads to a wide extension of the range of common fuels available, to practical elimination of clinkering, to great ease and economy of working, and to the production of a gas of unusually high value, as for example, CO_2, 10.6 per cent; CO, 18.8 per cent; H_2, 24.4 per cent; CH_4, 3.9 per cent; total combustible, 45.1 per cent; higher heating value, 182.5; lower heating value, 164.5 B.t.u. per cu.ft.

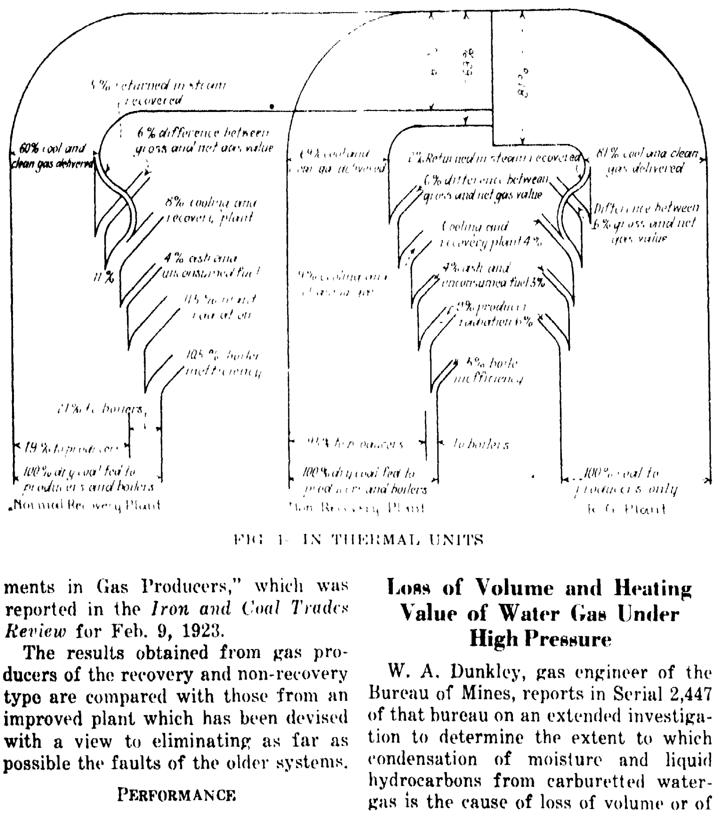

FIG. 1—IN THERMAL UNITS

Loss of Volume and Heating Value of Water Gas Under High Pressure

W. A. Dunkley, gas engineer of the Bureau of Mines, reports in Serial 2,447 of that bureau on an extended investigation to determine the extent to which condensation of moisture and liquid hydrocarbons from carburetted water-gas is the cause of loss of volume or of heating value of the gas. The work was done in connection with the distribution system of the Western United Gas & Electric Co., of Aurora, Ill. That system includes supply of gas over a territory 85 miles long by 35 miles wide at pressure ranging up to 90 lb. per square inch.

This work shows that the condensation of water vapor and of oil vapors in the distribution system does not ordinarily contribute materially to the loss in volume during distribution. Only when the inlet gas is metered at considerably higher temperature and then subsequently compressed and cooled is the volume decreased by as much as 5 per cent due to condensation. The effect on heating value under the conditions of test was a loss of approximately 9 B.t.u. per cubic foot, or 1.6 per cent, but it is believed that this might increase during extreme winter weather to 35 B.t.u., or 6 per cent of the initial heat value under extreme conditions. The full report can be obtained on application to the Bureau of Mines, Washington, D. C.

Silico-thermy and Its Practical Application

The reaction between iron and silicon is one producing a considerable evolution of heat. Therefore when soft iron and metallic silicon are heated together in a crucible to a temperature of about 1,250 deg. C., which is still considerably below the fusing temperature of either of them, a vigorous reaction ensues, the temperature rises rapidly to above 1,800 deg. C., the mass melts, and the whole contents of the crucible become an overheated liquid. If the charge was of about 80 per cent iron and 20 per cent silicon the product would have the composition of the silicide Fe_2Si, if 67 per cent and 33 per cent of FeSi. At intermediate percentages a more or less saturated solution of these silicides in iron is apparently obtained. As alloys so obtained are too brittle for practical use, a certain amount of carbon must be alloyed, whereupon alloys very suitable for making acid-resisting wares are obtained. In describing the process, R. Walter[1] suggests for these alloys the name of "Thermisilid." The valuable properties of "Thermisilid" are obtained because of its homogeneity, which is not attained in other high

[1]A paper read before the German Society of Metals, *Metallkunde*, 1921, pp. 225-233

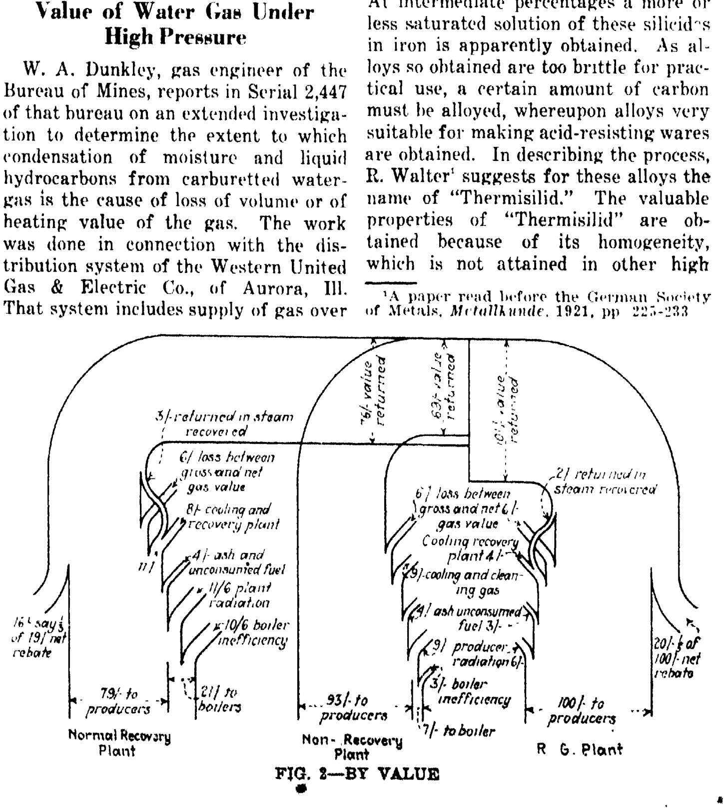

FIG. 2—BY VALUE

silicon irons. Numerous sections are described and the structure of the finished article given as that of polygonal crystals of Fe_3Si imbedded in the matrix of a solid solution of silicon in iron. Carbon is present in the ground mass as evenly distributed fine flakes of graphite.

During the verbal discussions in which, among others, Professors Arndt and Guertler took part, the suggestion was put forward by the latter that a low-melting eutectic might be formed at or about the temperature of 1,250 deg. The formation of the first liquid drop would thus liberate a certain amount of heat and facilitate the liquefaction of further quantities of the charge.

The analogy that exists between alumino-thermy and silico-thermy was also discussed, as well as the possibilities of numerous practical applications for industry.

Buildings From the Manager's Viewpoint

The manager of an industrial organization which is about to construct new buildings has many problems to solve quite outside the usual routine of manufacture. As a guide in the solution of these problems, G. L. H. Arnold has written an interesting article in the March, 1923, issue of *Management Engineering*. This article points out that the questions which arise are inevitable and depend entirely upon the industry for which the buildings are to be erected. Once a decision is reached on any of these problems and the building is erected, it is a fixture. Therefore thought must be taken before any building is started, so that nothing shall be erected which is a hindrance to future operations.

The principal concern of the manager in deciding the type of buildings to erect is with the effect of the new building on his output. In considering this phase of the matter, the following points must be taken account of:

1. Duration of occupancy.
2. Character of occupancy.
3. Extent and character of probable future growth.
4. Advisability of providing space to be rented.
5. Nature of materials used in manufacture.
6. Fire and explosion hazards.
7. Size and weight of units to be handled.
8. Methods of transportation within the building.
9. Class of machinery or equipment to be installed.
10. Receiving, shipping, and storage requirements.
11. Amount and character of departmental intercommunication necessary.
12. Type of labor employed.
13. Density and distribution of population in the neighborhood.
14. Economic arrangement of equipment.

The author goes on to enlarge on these various factors and points out particularly the responsibility of the management in deciding the story height, building width and column spacing carefully with relation to the industrial operations that are to be carried on in the building. In conclusion the paper states that the new building is a machine, each detail of which must be considered with relation to its effect upon the quality, quantity and cost of the product. The governing question as to size and type of industrial building in the last analysis is whether the benefit to the product is sufficient to justify the expense incurred.

Recent Chemical & Metallurgical Patents

Manufacture of Phenyl Glycine—There are several well-known methods for making synthetic indigo which start with aniline as a base, the principal intermediate product being phenyl glycine ($C_6H_5.NHCH_2.CO_2H$). One of the earliest methods developed for making phenyl glycine from aniline was by reaction with chloracetic acid in the proportion of three molecules of aniline to one of the acid. This process has, however, presented considerable difficulties, principally due to the formation of certain undesirable intermediates, such as anilide. These products, of course, affect the yield of phenyl glycine. In a process patented by Charles J. Strosacker, of Midland, Mich., and assigned to the Dow Chemical Co. of that city, the aniline and chloracetic acid are mixed in the presence of water, the water being approximately one part in four by weight of the combined mixture. The mixture is

American Patents Issued March 6, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem & Met* readers. They will be studied later by *Chem & Met.'s* staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,447,203—Process of Making Arsenicals. Carleton Ellis and Vernon T. Stewart, Montclair, N. J.

1,447,208—Composition of Matter for Use as a Roof Paint. Joe Power and Henry Wolfe, Sparta, Ill.

1,447,248—Smokeless-Powder Dynamite. Linwood H. Jones, Kenvil, N. J., assignor to Hercules Powder Co., Wilmington, Del.

1,447,296—Apparatus for the Combined Solvent and Destructive Distillation Treatment of Shale. David T. Day, Washington, D. C.

1,447,297—Process for the Combined Solvent and Destructive Distillation Treatment of Oil Containing Earthy Material. David T. Day, Washington, D. C.

1,447,344—Pulp Washing and Condensing Apparatus. Ira Thomas Fisk, North Hoosick, N. Y., assignor to Stevens & Thompson, Inc., North Hoosick, N. Y.

1,447,400—Process for the Manufacture of Alkaloids. Arthur Stall, Basel, Switzerland, assignor to Chemical Works, formerly Sandoz, Basel, Switzerland.

1,447,401—Apparatus for Producing Smoke. James N. Alsop, Owensboro Ky., assignor to Packer's Meat Smoking Corporation, Chicago, Ill.

1,447,452—Colloidal Decolorizing Material and Process of Producing the Same. Leonard Wilkenden, Flushing, N. Y.

1,447,461—Method for Employing Decolorizing Carbons and Other Absorbing Materials. Joseph Fergus Brewster, Clarendon, Va., and William G. Raines, Jr., Jackson, Miss., assignors by direct and mesne assignments to the Government of the United States and to the people of the United States.

1,447,485—Coloring Matters Derived From Pyrazolone. Emil Reber, Basel Switzerland, assignor to Society of Chemical Industry in Basel, Basel, Switzerland.

1,447,501—Process for the Preparation of Basic Salicylate of Aluminum. Jean Altwegg, Lyon, France, assignor to Société Chimique des Usines du Rhone, Paris, France.

1,447,544—Manufacture of Sodium Phosphate. Walter Glaeser, Brooklyn, N. Y.

1,447,557—Reduction of Nitrocompounds. David Alliston Legg, London, England, assignor to Matthews Atkinson Adam, London, England.

1,447,568—Process of Treating Lime-Containing Materials. Joseph Pelt, Cicero, Ill.

1,447,581—Apparatus for the Combustion of Poisonous Gases in Blast Furnaces. Johann Voegeli, Zurich, Switzerland.

1,447,645—Roasting Sulphur-Bearing Materials, etc. March F. Chase, Cleveland, Ohio, and Frederic E. Pierce and John Skogmark, New York, N. Y., assignors to the Cos Process Co., Inc., New York.

1,447,654—Method of and Apparatus for Drawing Sheet Glass. Arthur E. Fowle, Toledo, Ohio, assignor to the Libbey-Owens Sheet Glass Co., Toledo, Ohio.

1,447,661—Method and Apparatus for Flattening Sheet Glass. Seth B. Henshaw, Charleston, W. Va., assignor to the Libbey-Owens Sheet Glass Co., Toledo, Ohio.

1,447,689—Process of Reactivating Spent Catalyzers. William D. Richardson, Chicago, Ill., assignor to Swift & Co., Chicago.

1,447,930—Preparation of Preservative Substances for Rubber Latex. Samuel Cleland Davidson, deceased, late of Belfast, Ireland, by Frederick George McGuire, Bangor, Ireland, Alfred Agar, Holywood, Ireland, and Hugh Taylor Coulter, Belfast, Ireland, executors.

1,447,937—Process of Making Hydrochloric and Arsenic Acids. Carleton Ellis and Vernon T. Stewart, Montclair, N. J.

1,447,938—Process of Making Arsenate of Lime. Carleton Ellis and Vernon T. Stewart, Montclair, N. J.

1,447,954—Oxidizable Oil. Paul Wentworth Webster, Pelham Manor, N. Y., assignor to Perry & Webster, Inc., Elizabeth, N. J.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

then heated to a temperature at which the reaction starts, whereupon the heat is withdrawn and the action is allowed to proceed to completion. The aniline salt of phenylglycine and aniline hydrochloride are formed. Then a suitable neutralizing agent, such as sodium carbonate, is added in amount sufficient to react with the hydrochloride, with the result that it is decomposed into aniline oil and sodium chloride. After the products are allowed to settle and become stratified, the mixture of the aniline salt of phenylglycine and aniline oil is drawn off and treated with a solution of sodium carbonate to yield the sodium salt of phenylglycine and additional aniline oil. The latter is easily separated and returned to the process. (1,442,732. Jan. 16, 1923.)

Method of Making Phthalic Anhydride—Hidematsu Sasa, of Tokyo, Japan, has been granted a patent for the manufacture of phthalic anhydride from nitro-naphthalene. He claims that his product can be manufactured economically with sulphuric acid of ordinary strength and with a cheap metal such as iron or zinc as a catalyst. Other processes based on the oxidation of naphthalene often require the use of fuming acid and mercuric or other expensive salts as catalysts. In the process here described, 450 kg. of sulphuric acid, 65 deg. Bé., is heated to 150-160 deg. C., and then 35 kg. of nitro-naphthalene is added. After the latter has fused into the sulphuric acid, 80-90 kg. of iron borings or zinc dust is added during agitation. A temperature of 200 deg. C. is maintained until all the gases are driven off; then the temperature is raised about 300 deg. C. and phthalic anhydride is driven off and recovered by condensation at the proper subatmospheric pressure. (1,443,094. Jan. 23, 1923.)

Phosphate Fertilizers — Hermann Plauson, of Hamburg, Germany, has patented a process for preparing a satisfactory phosphate manure by simply grinding the insoluble crude phosphate with six times its own weight in water to which a little acid or alkali has been added. The beater mill employed in the process reduces the phosphate to practically a colloidal condition and in this form, after drying, it is claimed to be an excellent fertilizer in spite of the fact that it is regarded as an insoluble form under normal conditions. (1,445,167. Feb. 13, 1923.)

Production of Zinc Oxide—E. P. Stevenson has assigned to Arthur D. Little, Inc., of Cambridge, Mass., a process for making pure zinc oxide. Normally the color of zinc oxide is not absolutely white and is due to minute traces of other metals, such as copper, iron and cadmium. By digesting a roasted zinc ore with ammonium sulphate a precipitate of basic zinc sulphate is obtained, which is then washed and dried to decompose the ammonium salt. It is then digested further with soluble alkali, which converts the zinc into a mixture of zinc hydroxide and zinc carbonate. This mixture is finally dried and calcined at a low heat to produce commercial zinc oxide, which, however, has an extremely high purity due to the preliminary treatment. (1,445,366. Feb. 13, 1923.)

Agitator—The object of this invention is the construction of an agitator which automatically produces an influx of air into the agitated mass during operation. In order to accomplish this the rotating stirring device is provided with an air passage having an outlet so placed that it discharges the air directly into the agitated mass. The inlet of this air passage connects with a scoop for the entrance of air, which is drawn in by compression within the scoop and by the displacement of liquid produced during the rotary movement of the agitator. In operation air is forcibly ejected through the arms of the stirring device into the agitated material in such a way that a complete mixture of air and material is obtained. While this apparatus is particularly designed for the process of concentration by flotation in handling ores, it will have numerous other applications where agitation and separation or concentration are to be effected at the same time. (1,445,935. Arthur C Daman and Thomas J. Pennington. Feb. 20, 1923.)

Selenium Oxychloride as a Solvent—Victor Lenher, of Madison, Wis., has suggested the use of selenium oxychloride for dissolving unsaturated hydrocarbon compounds of various kinds. This includes rubber, both pure and vulcanized, Redmanol, Bakelite and Condensite, resins, glues, gelatin, celluloid, varnish, lacquer and paints. The solvent action may be increased by adding 20 per cent sulphur trioxide and diminished by diluting with carbon tetrachloride, 2.75 per cent by weight. (1,445,329. Feb. 13, 1923.)

Process for Making Plastic Compositions—A. A. Backhaus, of Baltimore, Md., has assigned to the U. S. Industrial Alcohol Co. a mixture from which a plastic composition may be made. The patent covers the use of ethyl aceto acetate as a camphor substitute in such compositions—for example, 10 oz. by weight of cellulose nitrate, together with a gallon of suitable solvent, such as acetone, amyl acetate, etc., and anywhere from 1 to 4 oz. of ethyl aceto acetate. After this material is hardened it behaves very similarly to the camphor-made product and it is claimed that ethyl aceto acetate provides flexibility and pliability, which obviates brittleness, opacity and blushing. (1,437,952. Dec. 5, 1922.)

Recovery of Waste Potash Liquor—C. T. Whittier has assigned to the Royal Baking Powder Co. of New Jersey a patent whereby the waste potash containing liquor from a tartaric acid manufacture may be recovered. Always in the past this material has been thrown to waste because, in evaporating, calcium sulphate separates out and the organic matter coagulates. This leaves a viscous mass very difficult to handle. By utilizing a spray drier it is possible to obtain this material in an available form. (1,442,317. Jan. 16, 1923.)

Production of Soluble Resins From Furfural—G. H. Mains and Max Phillips of the Department of Agriculture have developed nine soluble resins by heating furfural with the following substances: Meta-nitraniline, alpha-naphthylamine, para-toluidine, beta-naphthylamine, meta-toluylenediamine, methyl ethyl ketone ortho-toluidine, cymidine and xylidine. The process in general is to heat furfural with two parts of the other material (in some cases this is varied) for several hours under a temperature which varies from 150 to 200 deg. The various conditions are for the purposes of abstracts unimportant. (1,441,598. Jan. 9, 1923.)

Manufacture of Orthosulphonic Acids of Aromatic Amines—J. Baddiley, Joseph B. Payman and Harry Wignall, of Blackley, Manchester, England, have assigned to the British Dyestuffs Corporation, Ltd., the following process for the preparation of orthosulphonic acids of aromatic amines. The chlorsulphonic acid of the amines is dissolved in a suitable solvent which will be unattacked by chlorsulphonic acid (tetrachlorethane is used frequently in this work). This process gives often a chlorsulphate addition product which sometimes separates out as a precipitate and may be filtered from the solvent. The material is then transformed into the sulpho acid with the elimination of hydrochloric acid. (1,441,655. Jan. 9, 1923.)

Two-Stage Process for Coke Manufacture—The method for coking proposed by James G. West is a two-stage process intended to produce high-grade metallurgical coke from high-volatile coal which is claimed to be otherwise not suitable for this purpose. In the first stage some coal is carbonized for reduction of the percentage of volatile matter, preferably to about 17 to 20 per cent, but in no event less than 6 to 10 per cent volatile. This semi-coke is ground and mixed with more of the original coal and the mixture carbonized as usual. (1,445,735. Feb. 20, 1923.)

Use of Lepidolite in Vitreous Enamels—Alexander L. Duval d'Adrian, of Washington, Pa., has assigned to B. F. Drakenfeld & Co., of New York, a patent covering the use of lepidolite in vitreous enamels. Used either in the frit or in the ground mass, or in both, it is claimed that a higher grade stronger enamel is produced which is more serviceable and which does not crack or craze. Where tin oxide is used, it is claimed that this may be replaced in part by lepidolite, producing a higher grade product at lower cost. (1,443,813. Jan. 30, 1923.)

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Explosives—Salts of azidothiocarbonic acid, which may be obtained from sodium azide and carbon bisulphide, are used in priming compositions - for example, with phlegmatizing agents such as resin or paraffine solution. The lead salt is of special importance and can be obtained from the sodium salt by treatment with lead nitrate. (Br. Pat. 188,302; not yet accepted. H. Rathsburg, Fürth, Germany. Dec. 29, 1922.)

Absolute Alcohol—A continuous process for the production of absolute alcohol consists in mixing alcohol of 95 to 96 deg. Gay-Lussac with powdered quicklime or other suitable dehydrating agent and distilling the greater part in a continuous still, collecting the alcohol, and continuously withdrawing the remaining liquid mixture, diluting it with water and delivering it to a rectifier, where it is exhausted of its alcohol which is concentrated to 96 deg. and again subjected to dehydration. In the apparatus shown in Fig. 1 lime and alcohol are mixed in a large stirrer A and delivered by a valve B and pump C to a heater worm D and thence to a continuous still E with steam jacket F and stirrers. The alcohol is condensed in the heater D and cooler G and flows out through a testing device H. Only about three-quarters of the alcohol is thus distilled, the remaining liquor being continuously tapped off by a pipe e, diluted with water by a cock S and funnel T and delivered to a continuous exhauster KL, the lower part of which is provided with bubbling plates constructed so as to prevent incrustation with lime. The base M is heated by a steam bubbler which drives the alcohol into the upper part L of the column, where by means of a reflux N it is rectified to 96 deg. and may be withdrawn through a testing-device N^1, and returned to the apparatus for further dehydration. The calcic mud collecting at the base M is passed into an extractor Q with float q operating an exit valve R, whereby a constant level is maintained in M. In the simpler form of the apparatus shown in Fig. 2 the preliminary reaction between the alcohol and quicklime is dispensed with, the crude alcohol being delivered direct to the upper plate of the column K through a heater X heated by waste steam from the exhauster K. Pasteurized alcohol is drawn off from the column L by the pipe u to a measuring device U and thence to the still E, E^1 which carries a partition E^1 dividing the unheated portion E from the portion E^2 which is heated by the steam-jacket F. Quicklime is dropped into E in measured quantities by a rotating recessed plug tap P. It is stated that the testing device W also serves to separate any aldehyde products. If incomplete dehydration is required the pasteurized alcohol may be drawn off at U. Instead of quicklime, fused calcium chloride, anhydrous potassium carbonate, anhydrous sodium or copper sulphate or anhydrous sodium acetate may be employed (Br. Pat. 189,136; not yet accepted. Barbet et Fils et Cie., Paris. Jan. 17, 1923.)

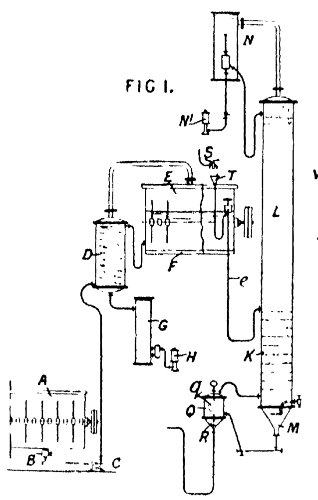

FIG. 1.

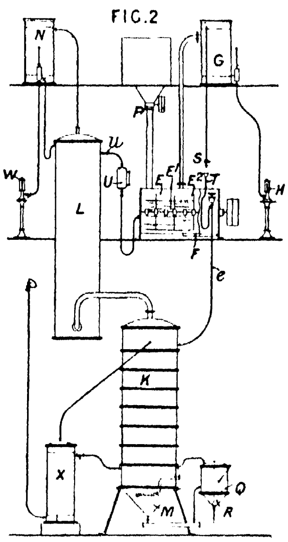

FIG. 2

Dyeing Cellulose Acetate—In the production of azo dyes on the fiber or material of cellulose acetate silk, films, etc., soluble salts are added to the baths containing the parent amines or the developers or to both; suitable salts are the chlorides of ammonium, sodium, potassium, barium, calcium, magnesium, zinc or tin, or sulphates of sodium, potassium or magnesium. Protective colloids, such as gelatine, boiled-off liquor, soaps, turkey red oils, etc., may also be added when the bases or developers are used in neutral or alkaline baths. In an example, acetate silk is first treated in a bath containing dianisidine hydrochloride, magnesium chloride and sodium bicarbonate, then passed to a diazotizing bath, followed by a developing bath containing alpha-naphthylamine hydrochloride and sodium bicarbonate, after which it passes to a second diazotizing bath and a second developing bath containing alpha-aminonaphthol, boiled-off liquor, and magnesium chloride; a black shade is obtained. Specification 176,535 is referred to. (Br. Pat. 187,964; not yet accepted. R. Clavel, Basel, Switzerland. Dec. 20, 1922.)

Dyeing—The waste liquor from aniline black dyeing in which ferrocyanide is used is treated with ferrous sulphate so that the liquor is acid or neutral, and the precipitated blue is separated. The precipitate, which is of no value as a pigment, is dissolved by treatment with an alkali, alkaline earth or ammonia a hydrate of iron being also produced. To the liquor is then added an excess of an organic or inorganic acid, or first a ferrous or ferric salt and then excess of the acid, when a blue precipitate is obtained which is a good pigment. (Br. Pat. 188,208. Bleaching and Dyeing Co., Ltd., and A. J. Hall, Congleton, Cheshire. Dec. 29, 1922.)

Carbon and Briquet Fuels—Peat, lignite, sawdust, or other carbonaceous material is preliminarily treated with a potassium or sodium salt such as carbonate, chloride, sulphate, acetate or phosphate, either by wetting the material with a solution of the salt or, if already wet, by intimately mixing with the salt dissolved in the least possible amount of water, and is then carbonized by roasting the mass on a hot plate while freely exposed to the air. According to an example, sodium carbonate or soda crystals are employed. To obtain a pure carbon the product is boiled with dilute hydrochloric acid and dried. The carbon produced may be worked up into briquets for fuel by use of a binder such as gluten, molasses or casein treated with formaldehyde. (Br. Pat. 188,807. A. M. Hart, London. Jan. 10, 1923.)

Extracting Copper, Lead and Silver Ores—Ores are treated with nitric acid of at least 40 per cent in the presence of iron or acid-soluble iron compounds equivalent to the metals other than iron in the ore, the iron nitrate produced being the effective attacking agent. After the separation of the iron hydrate, the nitrate solution may be treated with sulphuric acid to precipitate the lead and then by cementation to obtain first the silver and then the copper; or the solution after the removal of the lead and silver may be treated with sulphuric acid to obtain crystallizable sulphates which owing to their water of crystallization leave the liberated nitric acid in a concentrated state. Alternatively instead of cementation as above described the metals may be obtained by fractional electrolysis. (Br. Pat. 188,865. J. S. Wetzlar, London. Jan. 10, 1923.)

Technical News of the Week

Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Industrial Alcohol Interests Get Into Action on Drastic Restrictions

Sugar Men Turning Blackstrap Into Methanol—Senator Broussard Urges Utilization of All Available Waste

EVIDENCE is plentiful that the industrial alcohol situation rapidly is reaching a climactic stage. Prohibition enforcement officials propose more drastic regulations than those now in force. On the other hand, the chemical interests, including the sugar producers and those concerned with the expanded use of alcohol as a stove fuel and for internal combustion engine fuel, are ready to combat any more stringent regulations which tend to discourage the manufacture of industrial alcohol. More and more these interests are insisting on being relieved of the provisions of existing regulations which are throttling an industry of increasing importance.

Senator Broussard's Speech

It is understood that wide distribution is to be made of a recent speech made on the floor of the Senate by E. S. Broussard of Louisiana. Senator Broussard's principal interest in industrial alcohol springs from the sugar industry, with which he has been intimately associated all of his life. In the course of that speech, he said:

"While Australia recommends a bonus and many nations are appointing commissions to encourage the manufacture of industrial alcohol, we persist in this foolish course of prohibiting the manufacture of a commodity on the assumption that the manufacturer is a criminal and a crook and may interfere with some sumptuary measure. If we persist, we will find, within 20 years, when gasoline will be scarce, that the advances made in the internal combustion alcohol engines will have been made by foreigners, thoroughly safeguarded by patent rights."

A Crime to Discard Waste

In his address Senator Broussard contended that farm wastes should be made into alcohol. Such use should be made of surplus crops. He cited years in which farmers burned their corn as fuel because it was cheaper than coal and when millions of bushels of potatoes were allowed to rot in the field for lack of market. He pointed out a statement from the Bureau of Chemistry showing that alcohol could be made in 1922 at a cost of 6 cents a gallon from blackstrap molasses, and 7 cents a gallon from corn. "However," he said, "the hand of death was effectively laid upon such use of surplus materials by regulation No. 30, issued on Sept. 29, 1916, by the Commissioner of Internal Revenue. Although the statutes in the original form gave the right to the farmer to convert his waste products into industrial alcohol, these regulations absolutely defeat the law and make it impossible for him to do so."

In Hawaii the sugar producers long have made their own alcohol for use as motor fuel and for stove fuel. Just at this time the domestic sugar producers are taking up actively the use of their low-grade molasses in the manufacture of alcohol, due to the recent rise in the price of gasoline.

Calendar

The following important technical meetings are scheduled for the immediate future:

AMERICAN CHEMICAL SOCIETY
New Haven, Conn., April 3-7

AMERICAN ELECTROCHEMICAL SOCIETY
New York City, May 3-5

AMER SOCIETY MECHANICAL ENGRS
Montreal, May 28-31

AMERICAN FOUNDRYMEN'S ASSOCIATION
Cleveland, O., April 28-May 4

AMERICAN OIL CHEMISTS' SOCIETY
Hot Springs, Ark., April 30-May 1

SOCIETY OF INDUSTRIAL ENGINEERS
Cincinnati, O. April 18-20

SOCIETY OF CHEMICAL INDUSTRY
New York, regular meeting, March 23

SOCIETY OF CHEMICAL INDUSTRY
New York, joint meeting with other societies, April 20

Botanist Finds New Use for Aluminum Sulphate

Experiments conducted by Dr. Frederick C. Coville, a botanist of the Department of Agriculture, have developed the fact that aluminum sulphate when applied to ordinary soil is an effective and inexpensive method of changing the soil reaction from neutral or alkaline to acid. Where soils have been treated with crude aluminum sulphate marked stimulation of growth of certain plants has been noted.

To Study Chemical Tariff

Several Chemicals on List to Be Investigated in This Country and Abroad by Experts

The Tariff Commission, after reference to the President regarding its authority to proceed, has announced field investigations into seventeen commodities regarding which applications for changes in duties under the flexible tariff section of the new act have been received. Included are seven items in the chemical schedule: oxalic acid, paragraph 1, in which an increase is sought; diethyl barbituric acid and derivatives thereof, paragraph 5, increases sought; barium dioxide, paragraph 12, applications for both increase and decrease; casein, paragraph 19, increase sought; potassium chlorate, paragraph 80, applications for both increase and decrease; sodium nitrite, paragraph 83, increase sought; and logwood extract.

Investigations Abroad

Decision whether public hearings shall be held will be determined by the results of the field investigations. In any event several months must elapse before any definite results may be obtained. These investigations are to be carried on abroad as well as in this country.

Three representatives of the chemical section of the United States Tariff Commission will embark for Europe within a month to conduct investigations in connection with relative costs of production here and abroad of these chemicals. Germany, France, Switzerland and England will be visited in carrying out the study.

Personnel of Investigators

Dexter North and M. G. Donk will leave first and will remain as long as is required to complete the investigations. They will be followed by C. R. DeLong, chief of the section, who probably will remain abroad 2 months to supervise the work in Europe. On his return he will present a report to the commission regarding the changes that will be necessary. Much interest is aroused as to the outcome of the application of this flexible provision of the tariff.

Some difficulty is expected by the commission in obtaining foreign production costs in certain instances, but it has been suggested that the price level at which an imported article sold in this country over a given period could be used as a basis for comparison.

Comment on the Chemical Equipment Association

Notable Scientific, Commercial and Government Representatives See Benefit to Business

Many notable figures in chemical industry and the general world of chemical activity have recently commented approvingly on the activities of the Chemical Equipment Association. The association was formed a few months ago by leaders in equipment manufacture and now embraces a national membership of companies manufacturing essential equipment for the chemical, metallurgical and technical process industries.

Brigadier-General Amos A. Fries, chief of the Chemical Warfare Service, recently wrote to the association: "The activities of your organization, I believe, will be of great benefit to the general field of chemical industry." Charles L. Reese, chemical director of E. I. du Pont de Nemours & Co., expressed himself to the association recently as follows:

"I have no doubt that the Chemical Equipment Association can be of great value not only to the chemical equipment manufacturers but also to the chemical manufacturers. As an illustration of the co-operation between chemical manufacturers and the Chemical Equipment Association I might mention a recently appointed committee of the Manufacturing Chemists' Association for the standardization of the chemical ware forms which is to co-operate with a similar committee of the Chemical Equipment Association to bring about these standards, which will make it unnecessary for chemical manufacturers to maintain such large stocks of earthenware, glass, etc., for repairs when a great number of the equipment manufacturers hold in stock standard equipment."

A.C.S. Approves

"One of the most striking letters we have had," according to Pierce D. Schenck, president of the association, "is from the secretary of the American Chemical Society, Charles L. Parsons. Mr. Parsons has written us: 'I have watched with real interest the foundation of the Chemical Equipment Association. I believe it has a decided field for usefulness, and I am confident from the strong names that appear on your letterhead and from others whom I know to be members of your association, that it will do great good toward increasing the quantity and standardizing the design and use of chemical equipment and will be very helpful in the development of American chemical industry.' "

E. W. Washburn, chairman of the division of chemistry and chemical technology of the National Research Council, has also expressed his belief in the advantages to the chemical field as a whole that will accrue from the association, in a letter saying:

"In my opinion trade associations which cover both the producers and the consumers are in the long run likely to prove of the greatest advantage to both parties concerned. . . . The formation of these associations is an indication of great advances which the future will bring forth in the direction of co-operation between manufacturers and users and the increase of scientific knowledge which will result from the research work initiated and supported by such associations."

Malay Rubber Exports Grow Despite Drawbacks

Despite the restricting legislation of the British, rubber exports from Malay continue to grow. During January, 1923, 22,871 long tons of rubber was exported from British Malayan ports, as compared with 18,427 long tons in December, 1922, and 21,642 tons in November, the first month during which the restriction scheme was in effect, according to reports received by the Department of Commerce. The total of 62,940 tons during the 3 months may be compared with 55,257 tons during the corresponding period of 1921-1922.

Texas Engineers Stage Trip

Thirty-five junior and senior chemical engineering students of the Texas Agricultural and Mechanical College, accompanied by the head of the department, Dr. C. C. Hedges, made an interesting field trip on March 7 and 8 through Dallas plants. They inspected the Oak Cliff paper mill, the works of the East Texas Chemical Co., the Dallas sewerage disposal plant and the White Rock filtration plant. While in Dallas, the delegation attended a session of the local branch of the American Chemical Society, and later was present at a barbecue given by the Texas Portland Cement Co.

Yale to Do Silk Research

A fellowship has been established at Yale in silk research by Cheney Bros., silk manufacturers of South Manchester, Conn. This will be awarded to a graduate student who has shown special proficiency in chemistry and biochemistry and demonstrated his ability to pursue research work leading to the degree of Doctor of Philosophy. The recipient of this fellowship is to conduct research on some fundamental problem the solution of which will advance the knowledge of the chemistry of silk and substances and processes used in the silk industry.

Bauxite Again Mined in British Guiana

A considerable force of laborers has been placed at work at the mines and plant of the Demerara Bauxite Co., and it seems probable that a resumption of shipping of this material will begin shortly, according to a report to the Department of Commerce from Consul Chester W. Davis, Georgetown, British Guiana.

Olive Oil Foots Ruling Is Made Public by Treasury

Decision Makes Sulphur Olive Oil, Sulphured Olive Oil and Olive Oil Foots Duty Free

The contention between soap and oil importing interests is settled. No duty is to be levied on olive oil foots, according to the official ruling recently made public by the Treasury Department: The text of the ruling as made in the form of a letter from Assistant Secretary Moss to the Collector of the Port of New York is as follows:

The department refers to your communication of the 3d ultimo, in which you state that it is the practice at your port to pass ol've oil foots free of duty under paragraph 1632 of the tariff act as unfit for use as food or for any but mechanical or manufacturing purposes.

In view of the information supplied relating to sulphur olive oil, sulphured olive oil and olive oil foots, the department is of the opinion that the three names as used in the United States relate to one and the same article, it being an olive oil obtained by the use of a solvent known as carbon bisulphide or carbon disulphide.

Provision for Free Entry

The provision in paragraph 1632 for the free entry of olive oil rendered unfit for use as food or for any but mechanical or manufacturing purposes by such means as shall be satisfactory to the Secretary of the Treasury and under regulations to be prescribed by him, is a re-enactment of a previous provision which appeared in paragraph 639 of the tariff act of Aug. 5, 1909, and paragraph 561 of the tariff act of Oct. 3, 1913.

The department in T.D 29957 promulgated regulations in regard to the denaturing of olive oil under paragraph 639 of the tariff act of 1909, and in these regulations provided that "sulphured olive oil obtained by the extraction of olive oil from press cake by means of carbon bisulphide need not be further denatured."

In a later decision, T D. 34215, collectors were authorized to sample only 10 per cent of importations of oil invoiced as sulphured olive oil or olive oil foots or olive oil which had been rendered inedible abroad.

Provisions of Tariff

Under the provisions of the tariff acts of 1909 and 1913, above cited, merchandise known as sulphured olive oil or sulphur olive oil and olive oil foots was admitted free of duty and it must be presumed that the Congress had knowledge of the department's regulations authorizing the free entry of the merchandise under consideration, and the department is of the opinion, therefore, that its re-enactment of the provision in paragraph 1632 must be regarded as legislative sanction of the department's regulations and the practice of admitting this merchandise free of duty

In view of the foregoing, the department approves your practice of admitting free of duty sulphured or sulphur olive oil or olive oil foots under paragraph 1632 of the tariff act.

U. S. Wants Dust Engineers

Competitive civil service examinations are to be held on April 24 for assistant and associate dust explosion engineers, and on April 25 for junior dust explosion engineer. Entrance salaries will range from a minimum of $1,440 for junior engineer to a maximum of $3,000 for associate engineer. The duties of these engineers are to be in connection with investigations relative to the cause and prevention of dust explosions and resulting fires.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or secretary of the board of U. S. civil service examiners at the post office or custom house in any city.

Government Standardizes Metal Specifications

Organized Committee Now at Work Methods Being Employed Recognize Interests of Government and Industry

The Federal Specifications Board has appointed a technical sub-committee to which is assigned the task of coordinating all existing metal specifications of the several government departments and recommending such new specifications for metals as may be required. The personnel of the committee includes representatives of various technical and supply bureaus of the Navy, War, Commerce and Interior Departments.

Existing navy, army or other government specifications when available are used as a basis for the writing of all specifications. If no existing government specifications are available, commercial specifications such as those of the American Society for Testing Materials or Society of Automotive Engineers are made use of. When possible specifications from several sources are utilized.

How Specifications Are Drawn

Umpire methods of chemical analysis are being incorporated as a part of all specifications. The standard methods of chemical analysis adopted by the American Society for Testing Materials are being used where they apply. When the latter are not available, methods are being developed by the Chemistry Division of the Bureau of Standards. Preliminary specifications are submitted to authorities in the metal industries before adoption. The interests of both the industry and the government are considered in arriving at a satisfactory specification.

Work So Far Accomplished

The specifications before the federal board at present are: Pig lead; phosphor tin; silicon copper; ingot copper; ingot tin; slab zinc; phosphor copper; steel castings; foundry pig iron; high-test gray iron castings; gray iron castings; malleable iron castings; washed metal; silver solder; spelter solder; tin lead solder; manganese bronze castings; aluminum bronze castings; welding wire, iron and steel; copper-nickel alloy castings (Monel metal).

Huston Resigns to Head Huge Oil Corporation

Assistant Secretary of Commerce C. H. Huston has resigned to accept the presidency of the World Commerce Corporation, which has applied for a federal charter.

According to Mr. Huston, the World Commerce Corporation has been organized by substantial New York and Pittsburgh business men for the purpose of exploiting both foreign and domestic oil properties. The claim is made that "half of the oil-producing lands in the world" are controlled by this corporation.

Wainwright Urges Readiness

"Organization for rapid industrial mobilization is necessary," declared retiring Assistant Secretary of War Wainwright, "if we are to be prepared for another war." He also pointed out our specific deficiencies at the present time. His idea of the problem is that of insuring, "so far as foresight may provide, that our industrial establishment and factories be prepared upon outbreak of war to turn rapidly from their peace-time tasks to the production and creation of those things that shall have the primary preference."

The Three Essentials

Roughly, there are three great elements of supply to be provided:

"1. Those things which the ordinary or current productive capacity of the country can be relied upon to furnish.

"2. Technical supplies, such as munitions and aircraft.

"3. The strategic materials—namely, those not produced in sufficient quantity within the continental limits of the United States, such as nitrate, metal alloy, tin, rubber, platinum, tungsten and the like.

"This will show that unless we actually construct in time of peace sufficient reserves of certain vital equipment and accumulate working reserves of strategic raw materials we cannot produce within the continental United States we would not be able to hold our lines during the early period of the war."

Pulped Currency Used for Paper Making

The Forest Products Laboratory at Madison, Wis., has received from the Treasury Department 150 lb of currency cut up and pulped to be deinked and made into paper. It is estimated that the sheets of pulp represented approximately $2,500,000. The first run of paper made in the laboratory resulted in a poor quality because of a high percentage of foreign particles in the bills. Later runs indicate better success in making a clean product. As 2 to 3 tons of bills per day is macerated at the Treasury Department at Washington, the reclamation of the pulp is of importance even if the product can be used only for wrapping paper.

To Take German Nitrates on Reparation Account

Official announcement has been made that Germany has begun direct negotiations with Italy regarding deliveries of nitrates on the reparation account. A statement to this effect has been sent to the Reparations Commission in reply to an invitation that Germany enter into conference relative to such deliveries to France, Belgium and Italy. Owing to the Ruhr occupation, the German Government is not in a position to make deliveries to France and Belgium, and therefore has announced that it will not send representatives to the contemplated conference.

Founders Program Announced

Aluminum Alloys, Sand Investigations and Modern Developments in Foundry Practice to Be Discussed

Arrangements for the Cleveland meeting of the American Founders Association, April 28 to May 3, are nearly complete. The sessions and talks as planned cover a wide range of subjects. Probably of most general interest to all foundrymen will be the two sessions on foundry sand investigations. The joint sand investigation committee of the A.F.A. and the National Research Council will present progress reports of investigations of methods of testing sand, reclamation investigations and of progress in securing geological surveys of the foundry sand resources of the country. A great amount of work has been done by this committee since the Rochester meeting and much information of value to the foundrymen will be presented at these sessions.

Aluminum Alloy Session a Feature

The subject of aluminum and aluminum alloys will be considered at a joint session of the A.F.A. and the A.I.M.E. The developments in this branch of the industry have been so great that the papers committee decided to continue the practice inaugurated at Rochester of devoting at least one session to papers and discussion on this subject. In addition to the usual sessions on steel and cast iron there will be a session for the discussion of the new developments in the foundry world. The electric furnace and centrifugal casting will feature in this session.

The Institution of British Foundrymen will be represented on the program by an address by Dr. Percy Longmuir, one of the world's most foremost metallurgists, who has devoted his life to improving foundry practice.

National Safety Council To Hold Winter Meeting

Handling material, dust and fume hazards and traffic safety are the three main topics on the program of the meeting of the midyear conference of the National Safety Council to be held April 17 at Chicago, Ill.

The morning session will deal with causes of accidents in handling materials, and use of conveyors and trucks in eliminating material handling accidents, followed by a general discussion of specific safety problems in material handling. George T. Fonda, chairman of the Engineering Section of the Council, will preside at the morning meeting.

Preventing dust fires and explosions, health protection against dust, and a discussion of practical methods of dust and fume removal will follow in the afternoon. Homer E. Niesz, treasurer of the National Safety Council, will preside at the banquet in the evening, at which traffic problems will be discussed.

Eyesight Council Elects Officers for Coming Year

Important Work of Conservation Being Carried On in Schools and Factories —Officers Are Announced

A campaign to eliminate economic and physical losses due to poor eyesight in schools and factories is being carried on by the Eyesight Conservation Council of America. L. W. Wallace, executive secretary of the Federated American Engineering Societies, has been re-elected president of this association. Defective vision as a source of industrial waste was revealed by the Hoover Committee on Elimination of Waste in Industry, of which Mr. Wallace was vice-chairman.

Prominent Men Directing

Associated with Mr. Wallace as members of the board of directors and of the board of councilors of the Eyesight Conservation Council, according to the announcement of the election of officers for the coming year, are several prominent engineers, including Prof. Joseph W. Roe of New York University, president of the Society of Industrial Engineers; Dr. Morton G. Lloyd, chief of the Safety Section of the U. S. Bureau of Standards and vice-president of the American Society of Safety Engineers; G. E. Sanford of West Lynn, Mass., past-president of the American Society of Safety Engineers.

Recently Elected Members

Prof. F. C. Caldwell, of the department of electrical engineering, Ohio State University, and Secretary of Labor James J. Davis are recent additions to the governing bodies of the Eyesight Conservation Council. Engineering methods will be employed by the Council in surveys which are to be conducted in schools and workshops. Guy A. Henry of New York has been re-elected general director of the Council and will actively direct the eye campaign from the Council's national headquarters in New York City.

Wisconsin Metal Men Convene

At the request of the Wisconsin Foundrymen's Association, a statewide "Metals Convention" will be held at the University of Wisconsin under the auspices of the department of mining and metallurgy of the College of Engineering. There are 320 foundry groups with 700 different foundries in the state. During the convention a large exhibit of foundry machinery and equipment will be held in the University Stock Pavilion. The Society for Steel Treating will hold a meeting at the university at the same time and will have a separate exhibit of steel-treating methods, appliances and results.

The foundrymen are planning to organize at the convention a statewide association to further co-operation among themselves and with the university for the study of their technical problems.

Boll Weevil Fight Is On

Disagreement Between Active Agencies Does Not Interfere With Progress —Purchasing Bureau Projected

Although there is continued disagreement between the two great agencies aiming at extermination of the boll weevil—namely, the American Cotton Association and the National Campaign for Boll Weevil Control—still it appears that progress is being made.

Dr. Miller Reese Hutchinson has announced the co-operation of Luther Burbank in the N.C.B.W.C. From several statements made during the past week, it appears that Dr. Hutchison is to obtain much support in his campaign. The U. S. Department of Agriculture has signified its willingness to co-operate in every possible way.

Arsenate Agency to Be Formed

M. L. Tilton is in charge of an agency designed to stabilize the market for calcium arsenate. According to the plan a central purchasing bureau is to be established in New York which will contract with various manufacturers over varying periods. This agency will in turn distribute the material so purchased to state agencies, which will be placed in operation in each of the cotton states. The central agency will be placed upon a business basis and do business at sufficient profit to cover the expense of handling the work. Any surplus remaining after the expenses have been paid will revert to the National Campaign, to be used in still further pushing the work of eradicating the boll weevil.

Estimate of Available Arsenate

The amount of arsenate available for combating the weevil this year is far in excess of last fall's estimates. It is stated by R. N. Chipman, insecticide manufacturer, that 22,500,000 lb. of calcium arsenate is in sight. He adds, however, that because of an inactive market, exhaustion of this supply is not unlikely, because manufacturers are unwilling to put difficultly available white arsenic into a form which may not sell.

Government to Use Airplanes

Besides the use of arsenic in the usual manner several other ideas have recently been advanced. One of the most interesting is that of using army planes in spraying, an idea which has met with the approval of the Secretary of Agriculture, who has stated that planes will be used in Louisiana to spray calcium arsenate over experimental fields to determine just how efficacious the treatment from the air will be.

The Department of Agriculture believes that spraying the cotton plants twice daily with calcium arsenate broken into fine particles by the force of the propellers may control the activities of the boll weevil in such a way as to make cotton raising profitable, even in infested areas.

Makes Survey of Scientific Activities in United States

National Research Council Receives Report Concerning Details of Investigations

The co-operative scientific work carried on by the Federal Government and outside agencies is the subject of a report recently submitted to the National Research Council. According to this, there are 553 agencies engaged in research work in the United States, under which more than 1,100 co-operative undertakings are involved. Of these projects approximately 66 per cent can be described as engaged in the acquisition of new knowledge through scientific investigation. The remaining projects have directed their attention to technical service, the gathering of statistics and the enforcement of regulatory measures.

Agencies at Work

In the federal agencies engaged in co-operative work are included twenty-three bureaus and independent establishments maintained by the government. The outside co-operating agencies include various branches of the state governments, municipalities and Chambers of Commerce, endowed universities, etc.

According to the available data, more than $41,000,000 has been expended during the past year in the interests of federal and outside co-operators in definitely organized scientific work for the government. Of this amount, over $14,000,000 was supplied by the federal government, the balance being given by outside agencies.

In making this investigation, the central government had as its object the provision for more adequate scientific investigation of matters of general interest from a national or a regional viewpoint, and the promotion of nation-wide movements of various kinds. In general the forms of agreement or understanding entered into among these co-operating parties are for the purpose of avoiding misunderstanding and of fostering the spirit of co-operation.

Cleveland A.C.S. Hears Slosson

The March meeting of the Cleveland Section of the American Chemical Society was held in co-operation with the Cleveland Engineering Society, Tuesday, March 20, 1923. Dr. Edwin E. Slosson addressed the meeting, to which the Cleveland Chamber of Commerce was invited, on "Chemistry Applied to Industry."

Molybdenum Source Found

A deposit of blue molybdenum ore, rare in the United States, has been discovered near Ouray, Utah. This is the largest known source in the country. A report on this ore is to be issued in the near future by Dr. F. G. Hess of the Geological Survey.

A.C.S. Spring Meeting Plans Near Completion

New Haven Accommodation Problem Being Worked Out—Details of Social Affairs Arranged

In spite of the fact that practically all available hotel rooms in New Haven have been already reserved for the week of April 2 to 7, the executive committee of the American Chemical Society has arranged through the kindness of the people of New Haven to take care of everybody who comes. The Y.M.C.A., Y.W.C.A. and Chamber of Commerce of New Haven have furnished the hotels committee a large list of private homes where rooms may be obtained for the week. To give the local committee ample time, everyone who plans to attend is requested to write as soon as possible to Dr. Ralph Langley, 84 McKinley Ave., New Haven, regarding room reservations. The committee gives assurance, however, that last-minute reservations will be provided.

Council and Reunion Dinners

The councilors' dinner on Monday night is also open to all members of the A.C.S. who purchase tickets obtainable at Byers Hall. An attractive program has been arranged including brief addresses by noted and able speakers.

The time between the close of the section meetings and the polo game on Thursday will be devoted to fraternity and alumni dinners. These "reunion" dinners should prove a very attractive feature of the meeting. All organizations or groups wishing to get together for a dinner should communicate at once with Dr. Arthur H. Smith, 84 Woodlawn St., Hamden, Conn.

As a matter of convenience it will not be necessary to arrange Pullman reservations for the return trip at the railroad station, facilities for this being provided at headquarters at Byers Hall. This service will be in charge of N. C. Magnus, whose office is located at 219 Elm St.

Metal Inquiry Proceeds

Delayed organization of the commission to investigate the gold and silver situation has resulted from the absence and illness of several of its members, including that of the proposed chairman, Senator Nicholson of Colorado.

This time will not be lost, however, as literature on the subject is being assembled and abstracted. Abstracts also are being made of the experiences of commissions and committees which have investigated monetary or precious metal questions in the past. An analysis is being made of freight rates on gold and silver ore as compared with the rates on other commodities. Other basic information is being gathered so that the commission when it meets in April will have before it in concise form the results of similar inquiries in the past and certain other data which will make possible a more intelligent determination of the scope of this investigation.

Paper Exhibition Progress Indicates Success

The list of exhibitors at the Paper Industries Exposition, which is to open at Grand Central Palace, New York, on April 9, indicates that the story of paper is to be well told. Final plans are being formed for the conventions of the T.A.P.P.I. of the A.P.P.A. and of the National Paper Trade Association, all of which fall during the week of the exposition. Government films dealing with the forestry end of pulp are to be shown, and special programs have been arranged on different days. The exhibits are to cover practically every phase of paper making from preparation of raw material to the testing of the finished products. At present the number of exhibits arranged for is approximately sixty. Of especial interest to students of the industry will be the government and Forest Products Laboratory booths.

Montana Arsenic Source To Be Developed

A development of interest has recently taken place in the production of arsenic. The district about Jardine, Mont., has long been the scene of gold mining; but the operations there have been greatly hampered by the arsenical character of the pyrites in which most of the gold values are found. It is now proposed to develop the recovery of arsenic to as large an extent as the market will warrant.

The Jardine Mining Co. has erected a reverberatory furnace with arsenic kitchens, for the purpose of roasting its concentrates and extracting arsenic. The production is 100 tons of white arsenic per month on the present scale of operations. The ores appear to be entirely free of antimony, bismuth or any other element which would interfere with the production of high-grade arsenious oxide.

The present production of this new plant will make no increase in the country's supply of arsenic, as the same amount was formerly removed at the A.S.&R. smelter in Tacoma, Wash., where the Jardine concentrates were shipped. The deposits at Jardine, however, cover a large area, most of which is yet undeveloped; and, when the investment is warranted by the demand, it is expected that the output of the Jardine property will be greatly increased.

Seeks Graduate Assistants

Dean Ketchum, of the College of Engineering, University of Illinois, announces that fellowships are available at that institution for work in engineering research. This may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering and theoretical and applied mechanics.

New Jersey Chemists Hear Prominent Speakers

Brigadier-General A. A. Fries and Dr. Hugo Schlatter Address March Meeting

Growing enthusiasm was evidenced in the March 12 meeting of the New Jersey Chemical Society by the fact that the largest crowd ever turned out was on hand to hear the two speakers of the evening, Brigadier-General A. A. Fries, chief of the Chemical Warfare Service, and Dr. Hugo Schlatter, of Philadelphia.

The Artificial Silk Industry

Dr. Schlatter in his talk brought out many interesting points in regard to the artificial silk industry. He outlined its development from early days, the mechanics of the four usual methods involved in its fabrication, the chemistry of these methods and the general economics applying. He made the point that cuprammonia silk is most largely manufactured in Germany, where it was discovered; nitrocellulose silk in France, where Count de Chardonnet first made it; while viscose silk, of Anglo-English origin, is the major industry in England and the United States. In 30 years the annual consumption of artificial silk of domestic manufacture has grown to 30,000,000 lb. in the U. S.

General Fries on War Gas

Unusual moving pictures and photographs of maneuvers with gas on land, on sea and in air attended General Fries' talk on "War Gas, Past, Present and Future." The fact that the press has vastly exaggerated the deadliness and misrepresented the effects of war gases was emphasized by General Fries, who also spoke of the research now being carried on at Edgewood, where the toxic effect of various gases is being studied and new methods of manufacture are being evolved.

Demonstrates Improved Naval Stores Production

Practical, profitable methods of producing rosin, turpentine and similar naval stores are to be demonstrated by G. P. Shingler, government expert, to interested parties in the South during the next 6 weeks. Mr. Shingler will confer with individual producers who may need and desire his advice, assistance and suggestions regarding improvements in operation.

Headquarters at Savannah and New Orleans

Mr. Shingler will have his headquarters during the remainder of March in the U. S. Custom House, New Orleans, La., and during the month of April in the U. S. Custom House at Savannah, Ga. It is suggested that producers desiring to confer with Mr. Shingler write to him in order that arrangements can be made for a conference either at his headquarters in one of those cities or at the place of the producer.

Salesmen Hold Alkali Dinner

Caustic Remarks Not in Evidence at Regular Monthly Program—Roth and French Give Talks

The New York Section of the National Association of Chemical Salesmen held a most successful dinner at the Chemists' Club on March 14. There was plenty of enthusiasm and at the same time an increased evidence of seriousness of purpose and constructive thought. On behalf of the members of the association who attended the lectures given by Dr. F. E. Breithut on chemistry, Mr. Ashbridge presented him with $70 in gold. Dr. Breithut replied felicitously and announced that if the members of the association were interested in pursuing the work next year, he would be glad to arrange it.

With Mr. Dorland as master of ceremonies, Mr. Boyer, the national association president, and Edward Signor were introduced. Both of these men discussed the problems that confront the association and offered suggestions as to the necessary work.

Charles Roth, of the International Exposition Co., spoke on the policy of his company with reference to the Chemical Exposition. He earnestly requested the members to make definite criticisms. The exposition could be successful only if it was representative of all phases of chemical industry and supported by everyone.

E. P. Finch, of the Alkali Export Association, reported a very interesting change in the attitude of the South American countries toward American heavy chemicals. From suspicion and even hostility, they have changed to a receptiveness and even an eagerness to deal with us.

France Lifts Double Duty

More than $30,000,000 worth of goods purchased by the Allies in the Ruhr previous to French occupation are released from the additional duty of 10 per cent which has been imposed. Chemicals, textiles, dyestuffs, steel and machinery which have been held because of the exporters' refusal to pay the double duty imposed will begin to move again if the French official action of release takes its expected effect. Traffic conditions in the Ruhr for these goods are reported by the French as being favorable. Contracts involving unfinished goods, however, are not subject to this tax-exempt ruling, it is understood.

Dust Hazards Report Coming

A report covering the work of the dust explosion hazards committee of the National Fire Protection Association is about to be issued. This will cover tentative regulations for the installation and use of grinding and pulverizing systems for sugar; for the installation and use of pulverizing fuel systems, and for the prevention of dust explosions in terminal grain elevators.

Export Association to Handle Rubber Commodities

Papers have been filed with the Federal Trade Commission for the formation of a rubber export association. This organization, which will include the United States Rubber Export Co., the Goodyear Tire & Rubber Export Co., and the Miller Rubber Export Co., will not be incorporated, however, but will operate along mutual lines in exporting manufactures of rubber and commodities of the rubber industry.

The three companies, it was stated, will use their own individuality and trademarks, but will probably maintain joint offices abroad, with a single sales force. J. B. Tower, of New York, has been named secretary.

Rubber Trouble Continues

Varying Viewpoints Advanced by American and British Interests Concerning Solution

The controversy over the rubber situation grows. Despite unofficial American protest, the British viewpoint, as voiced by such men as Winston Churchill, defends the Stevenson plan. This plan, providing for reduced production of raw rubber in Malay, is aimed to bring up the selling price of rubber to cover production costs. Consumers in the United States believe, however, that Britain is taking unnecessary means of bringing about this end.

The directors of the Rubber Association of America have made the following recommendations to the Rubber Growers Association of London:

"1. That the Stevenson plan for the restriction of crude rubber exports from British Dominions be abolished in its entirety, this recommendation being predicated upon the firm belief that the natural conditions of supply and demand now existing will fully protect the plantation industry.

"2. A request for immediate consideration by the Colonial Government's advisory committee, of which Sir J. Stevenson is the head, of the announcement by the British colonial or the local colonial governments that it use its discretionary powers with respect to the application of this scheme and release rubber without regard to quarterly periods or prices if necessary to prevent wild fluctuations as part of a speculative movement."

Government Action Advocated by Firestone

The group of American rubber men led by Harvey Firestone believes that government action in the matter is desirable. It is now certain that a survey of possible new sources of rubber for United States consumption is to be made. Secretary Hoover has invited the various rubber interests to co-operate with the government in organizing this work. The Philippines and Amazon Valley are considered to be the best fields for investigation.

Paint Men Make Known Activities of Association

G. B. Heckel, Secretary, Shows Facts of Case and Claims No Need of Vindication

From a recent statement of G. B. Heckel, secretary, the public obtains a clear-cut outline of the activities of the Paint Manufacturers Association, which for the past 2 years has undergone investigation by the government and against which, as was stated in *Chem. & Met.* last week, no charges have been sustained.

The statement says in part:

The last thing our organization has ever contemplated was control of prices. Our organization devotes itself to the improvement of the paint industry and the correction of evil practices, such as misbranding, mislabeling, unfair competition and bribery. Among our activities we conduct a research laboratory at Washington, at the cost of $50,000 a year; an unfair competition bureau at Washington, at a cost of $15,000 a year, and a "Save the Surface" campaign, with headquarters in Philadelphia, which is for the creation of greater demand for paint and kindred products, and which costs $200,000 annually All of these agencies for the benefit of the paint business are open to paint manufacturers of the country whether they are members of the association or not

In view of these activities for the general good of the business it is hard to understand how there can be any machinery for price fixing. The Sherman act is a very ill-defined law which may be unknowingly violated by the most innocent. However, it would not require an indictment to induce an association like that of the paint manufacturers to correct any tendencies which might have existed toward its violation. As a matter of fact, the association has carefully followed the interpretations of the Sherman law with a view to avoiding any possible infraction. It will continue this policy in the future.

Food Standards Discussed

The Joint Committee on Definitions and Standards held its twenty-fourth meeting in the Bureau of Chemistry, March 12 to 16. Consideration was given to definitions and standards for a number of food products. The committee is composed of Dr. W. W. Skinner, chairman; Dr. F. C. Blanck, and R. E. Doolittle, representing the United States Department of Agriculture; Dr. J. Hortvet, of Minnesota, Dr. C. D. Howard, of New Hampshire, and Dr. E. M. Bailey, of Connecticut, representing the Association of Official Agricultural Chemists; Dr. L. E. Sayre, of Kansas, Dr. W. W. Randall, of Maryland, and Dr. R. E. Rose, of Florida, representing the Association of American Dairy, Food and Drug Officials.

Sulphur Agreement Framed

According to dispatches from Rome the Sulphur Export Association has signed an agreement with representatives of the Italian Government, regarding the control of sulphur sales in Europe. Under it the Italian Government will control the output of the Sicilian beds and will co-operate with the three leading American producers, the Union Sulphur Company, the Texas Gulf Sulphur Company and the Freeport Texas Company in meeting European demands.

Personal

H. E. BARNARD, director of the American Institute of Baking, was in New York, March 10 and 11, to attend the formal opening of the laboratory of the Fleischmann Co.

Colonel LEWIS T. BRYANT has been reappointed State Commissioner of Labor, New Jersey, by Governor Silzer, for a new term of 5 years.

E. J. CUTHBERT, formerly vice-president of the Solar Refining Co., Lima, Ohio, manufacturer of refined oils, has been elected president of the company to succeed J. G. NUBAUER, resigned. N. D. KEYS, heretofore general superintendent, has been appointed secretary and treasurer, succeeding F. G. BORGES, who has been elected vice-president.

P. M. DINKINS, formerly of the Dorr Co., has been made sales manager of the division of heavy chemicals with the Kalbfleisch Corporation, New York City.

General AMOS A. FRIES, head of the Chemical Welfare Service, has discussed the work of this bureau in two recent addresses, one before the New Jersey Chemical Society and the other before the Phi Lambda Epsilon fraternity, Columbia University.

W. S. FRISBIE, Office of Co-operation, Bureau of Chemistry, is conferring with the New Jersey and Delaware state and city officials on the co-operative enforcement of state and federal food and drug laws.

HERBERT S. HARNED, assistant professor of physical chemistry, University of Pennsylvania, Philadelphia, spoke before the Franklin Institute, March 15, on "Radiation and Chemical Reaction."

B. OLNEY HOUGH, for many years editor of the *American Exporter*, has resigned that position to establish himself as an expert counselor, consultant and adviser to banks, exporters and manufacturers. His office is at 17 Battery Place, New York City. He will continue his relations with the *American Exporter*, with the title of contributing editor.

Dr. SABASTIAN KARRER, of the Fixed Nitrogen Research Laboratory, addressed the meeting of the American Physical Society recently on subjects of thermal and electrical ionization as related to problems of nitrogen fixation.

WALLACE MONTGOMERY has been made superintendent of the Central Moron of the Eastern Cuba Sugar Corporation. For some time past he has been assistant superintendent.

A. H. NICKERSON, who since 1904 has been with the American Agricultural Chemical Co., has resigned to accept a position with Stone & Webster, Inc., in the mechanical division. Mr. Nickerson started with the former company as chief engineer, holding that position until 1921, when he was made manager of the manufacturing department.

R. B. MOORE, chief chemist of the Bureau of Mines, has accepted an invitation to deliver an address before the New York Section of the Société de Chimie Industrielle of France, on the occasion of the meeting to be held on May 11.

R. J. QUINN has been transferred to New York City as assistant sales manager of the Mathieson Alkali Works, Inc. JOHN W. BOYER, formerly assistant sales manager, becomes sales manager, and J. A. KIENLE, former sales manager, is now vice-president in charge of sales.

PAUL C. SCHRAPS, of the South American Development Co., sailed March 5 from San Francisco for Ecuador, South America.

A. D. SHAMEL, Bureau of Plant Industry, sailed from San Francisco, Feb. 17, for Honolulu, where for several months, while on furlough, he will continue the work begun in 1920 under the auspices of the experiment station of the Hawaiian Sugar Planters' Association in the application of the principles of the improvement of plants through bud selection to the propagation of sugar cane. Mr. Shamel has spent several months each winter since this work was begun in Hawaii developing it. Through the selection of propogating material a large increase in the yield of sugar has been obtained. While absent in Hawaii Mr. Shamel will further develop the selection work with sugar cane and will endeavor to perfect the methods and to extend their application to the entire sugar industry of the islands.

J. THOMPSON SMITH, at the annual meeting of the stockholders of E. I. du Pont de Nemours & Co., was made general manager of the company's explosives department to succeed the late Charles A. Patterson.

Dr. F. P. VEITCH, chemist in charge of the leather and paper laboratory, Bureau of Chemistry, has been appointed a member of the paper specifications committee of the joint committee on printing, which will prepare standard specifications and samples of paper suitable for the government printing and binding.

JAMES A. WATSON, assistant in the experimental work incidental to the introduction of the Allen process at the du Pont Nitrate Co.'s oficina, in Taltal, Chile, in 1920, and since in charge of the plant, has been appointed assistant manager.

Dr. E. R. WEIDLEIN, director of Mellon Institute, Pittsburgh, Pa., spoke before the members of the Hercules Powder Co., Wilmington, Del., March 5, on the subject "Value of Industrial Scientific Research." The meeting was held at the Trinity Parish House and members of the Delaware Section of the American Chemical Society were invited to attend.

Obituary

Prof. EDWARD WILLIAMS MORLEY died at Hartford, Conn., on Feb. 24. He was probably most widely known for his association with Prof. A. A. Michaelson in the far-famed Michaelson-Morley experiment in relation to the velocity of light. For this work he received the Sir Humphry Davy medal in Great Britain in 1907, while Professor Michaelson received the Nobel prize the same year. There are, however, many other records of major research which stand to Professor Morley's credit. His work on the densities of oxygen and hydrogen in the ratio of their atomic weights was a classic contribution to scientific knowledge, and about forty more papers of profound scholarship and of leading importance were published by him. These included repetition of the Michaelson-Morley experiment in view of the Lorentz-Fitzgerald suggestion that the form of bodies may depend on translation through space or through luminiferous ether. Other contributions were on the atomic weight of oxygen, on variations of the amount of oxygen in the air, the vapor density of mercury from 0 to 100 deg., etc.

He was president of the American Association for the Advancement of Science in 1895, and of the American Chemical Society in 1899. He was honorary chairman of the Eighth International Congress of Applied Chemistry at New York in 1912, and had been made honorary chairman of the spring meeting of the American Chemical Society that convenes at New Haven next month. In 1912 he received the Elliot Cressom medal, and in 1917 the Willard Gibbs medal was awarded to him.

Professor Morley was the son of a clergyman, and was born at Newark, N. J., Jan. 21, 1838. He was graduated at Williams College and later received honorary degrees from Yale, Lafayette and the University of Pittsburgh. In 1868 he was appointed professor of chemistry at the Western Reserve University at Cleveland, and held the post for 38 years, until his retirement in 1906. He then took up his residence at West Hartford, Conn., where he had lived with his parents as a boy.

He was married to Isabella Ashley Birdsall in 1868, whose demise preceded his by only 3 months. Immediately after her death he made a gift of $5,000 to the First Church of Christ of West Hartford in her memory, and, later he underwent a major operation at the Hartford Hospital from which he did not recover.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Problem of Maintaining Standard Prices

New Legislation Needed to Clear Up Uncertainties in Important Business Practice

One of the weighty problems facing the manufacturer is the policy of maintaining standard prices for the retail sale of his products. Can he refuse to sell to a retailer or jobber who markets his products at prices lower than the standard schedules set by the producer? Can a manufacturer decide to market his products solely through wholesale channels and then in order to maintain this policy, refuse to sell to a retailer at the jobber's price no matter what the quantity of merchandise involved? These are the questions that have been involved recently in some very important litigation - the Colgate and Beech-Nut cases before the Supreme Court and the Mennen case just decided by the United States Court of Appeals for the Second District.

These decisions, however, do not eliminate the element of uncertainty, for they do not tell the manufacturer just how far he can go in naming his own prices and thus protecting his own property. It is believed by many that the situation will not be cleared until there is definite legislation recognizing the principle of price standardization.

Proposed Legislation

When the last Congress adjourned two bills were pending that were designed to meet this situation. One of them is the Kelly-Stephens bill, originally drawn by Justice Brandeis before he became a member of the Supreme Court, and the other is the Merritt bill, introduced by Representative Merritt of Connecticut, which contains suggestions from Secretary of Commerce Hoover.

The Kelly-Stephens bill would set up machinery for price standardization to permit any independent manufacturer of a standard, identified article to file a schedule of his prices with the Federal Trade Commission. He would have authority to maintain the retail prices of his article or articles, but under section 3 of the bill the Federal Trade Commission may, on complaint of any person, investigate the standard prices so fixed to determine if they are fair. Under another section of the bill a retailer handling the standard price articles would be required to offer them for sale to the manufacturer at the price he paid for them before he would be permitted to offer them for sale to the public at prices lower than the standard fixed prices.

The Merritt bill is more simple and is confined largely to legalizing the principle of price standardization. It would permit the producer or manufacturer to fix his price and to refuse to sell to any dealer who cuts the fixed price. It provides no machinery, but if enacted into law would be rather an expression by Congress of recognition of the principle of price standardization and maintenance.

No Evidence of Price Fixing on Calcium Arsenate

Report of Federal Trade Commission Shows No Cases of Unfair Trade Practices

In its preliminary report on the calcium arsenate industry, made in pursuance to Senate Resolution 417, the Federal Trade Commission reaches the conclusion that "the evidence thus far obtained does not show that the prices (of calcium arsenate) were fixed by agreement." In the commission's detailed report a great deal of correspondence among the different manufacturers is cited and competitive conditions have been carefully analyzed. Although the producers have made a close co-operative study of prices and have discussed them at various meetings of their trade associations, there was no evidence of unfair practices such as price fixing and open-price activities.

From the facts assembled in this preliminary report, the commission submits the following conclusions:

1. That the great increase in the Southern demand for calcium arsenate and the inadequacy of the available supply of white arsenic prevented the insecticide manufacturers from producing sufficient quantities of calcium arsenate to meet this demand, the result being a marked increase in the price of white arsenic and of calcium arsenate during the seasons of 1922 and 1923.

2 The low price paid in the State of Georgia during the term of the Sherwin-Williams contract with that state was in part, at least, responsible for the opinion that an injustice was being done by the insecticide manufacturers to those customers outside the state who were paying a price as high in some cases as 100 per cent greater than that named in the above-mentioned contract, an opinion which was shared by the Georgia consumers after the expiration of this contract, when they likewise had to pay similarly high prices for calcium arsenate.

3 While efforts were made by the insecticide manufacturers to establish an association one of the objects of which seems to have been adjusting or at least discussion of price discrepancies, it does not appear that these efforts resulted in price fixing or open-price activities

4. No widespread or important specific cases of unfair practices in the trade have been found down to the present stage of the inquiry.

Fixing Standards for Naval Stores

Details of Harrison Bill to Establish Grades and Prevent Unfair Practices

During the session of Congress that ended on March 4 there was considerable discussion of naval stores, both as regards co-operative marketing and in the standardization of the many grades and varieties of these products. The Harrison bill, which passed the Senate but was not acted upon by the House, provided the establishment of standard grades of naval stores and also would make unlawful any untruthful representations in the sale or advertising of rosin and turpentine.

The various grades of rosin, from highest to lowest, are to be designated by the letters X, WW, WG, N, M, K, I, H, G F, E, D and B, together with the designation "gum rosin" or "wood rosin."

Turpentines were defined thus:

"(B) Spirits of turpentine" includes gum spirits of turpentine and wood turpentine.

"(C) Gum spirits of turpentine" means spirits of turpentine made from gum (oleoresin) from a living tree

"(D) Wood turpentine" includes steam-distilled wood turpentine and destructively distilled wood turpentine

"(E) Steam-distilled wood turpentine" means wood turpentine distilled with steam from the oleoresin within or extracted from the wood

"(F) Destructively distilled wood turpentine" means wood turpentine obtained in the destructive distillation of the wood.

Fines not exceeding $5,000 and 1 year imprisonment are provided for the "use in commerce of any false, misleading, or deceitful means or practice in the sale of naval stores or anything offered as such."

Upon application, the Secretary of Agriculture would be required to make an analysis of any naval stores and certify as to their classification.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	179.51
Last week	176.76
March, 1922	156.00
March, 1921	157 00
March, 1920	252.00
April 1918 (high)	286 00
April, 1921 (low)	140.00

A marked increase in the index number this week can be traced to the stronger markets for ammonium sulphate, cottonseed and linseed oils. Ammonium sulphate advanced to $4.15 per 100 lb., cottonseed oil to 10.5c. per lb. and linseed oil to 99c. per gal.

A. S. & R. Wipes Out Deficit

The annual report of the American Smelting & Refining Co. shows that the company's net income in 1922 after providing for general expenses, depreciation, etc., taxes and interest amounted to $5,918,142.94, an increase of $4,207,201.83 over the preceding year. After payments of dividends on preferred stock, there was a surplus of income of $2,003,112.94 at the end of 1922, compared to a deficit of $2,457,102.64 at the close of 1921. The surplus disclosed by the report is equal to earnings of approximately $3.28 on the common stock.

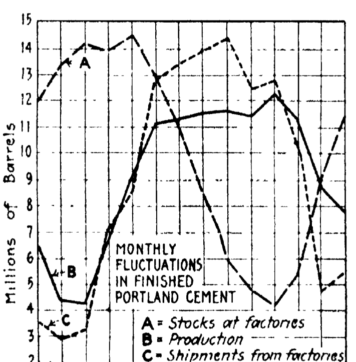
As an incident in the letter of the president of the company it is reported that the production of various important metals and the output of byproducts also showed marked improvement in 1922 over 1921 as follows:

	1922	1921
Copper (lb.)	433,548,000	348,888,000
Silver (oz.)	84,793,931	75,354,443
Lead (ton)	252,898	207,612
Spelter (lb.)	35,140,000	14,628,614
Sulphuric acid (lb.)	28,494,000	9,952,000
Arsenic (lb.)	11,203,052	5,155,522
Byproduct metals (lb.)	12,710,577	5,232,48

The report also shows that the production of some of the above, notably spelter, sulphuric acid and arsenic and the output of byproduct metals, last year greatly exceeded their production in 1913.

Cement Production Twice That of Year Ago

Preliminary figures just announced by the Bureau of the Census indicate that the output of portland cement during February, 1923, was almost double that of February a year ago. The total of 8,085,000 bbl. is an increase of 381,000 bbl. over the preceding month.



CEMENT OUTPUT, SHIPMENTS AND STOCKS

Shipments in February totaled 5,963,000 bbl. and stocks on hand at the end of the month were 13,592,000 bbl. These may be compared with the corresponding figures for last year by means of the accompanying chart showing the monthly fluctuations in production, shipments and mill stocks throughout the country, Dec. 1, 1921, to Jan. 31, 1923.

Ammonium Sulphate Advanced by Producers in a Moderately Active Market

Difficulty in Locating Imported Goods Is Still Evident—Alkali Sales Show Improvement—Vegetable Oils Are Advanced

NEW YORK, March 19, 1923.

THE chemical market during the past week continued along moderately active lines. Sales were in most instances for small orders for immediate requirements and buyers seemed quite cautious about purchasing any surplus stocks. Existing conditions in the Ruhr district have caused a noticeable shortage of importations and several items have already been advanced by second hands. Producers of ammonium sulphate advanced prices for bulk goods at the works. Spot goods for export were also sharply advanced due to the acute scarcity of any large supplies. The alkali market showed a slight improvement and several fair-sized contracts were placed for Japan and Italy. Soda ash also recorded a fractional gain. Permanganate of potash was sharply advanced during the early part of the week, but reacted later and quotations were at the same level as previously reported.

Barium carbonate and chloride were advanced by importers, due to the shortage of shipments. Arsenic continued without any special feature and prices were unchanged. Bleaching powder producers reported a favorable market, with demand up to all expectations. Carbonate of potash was much firmer, although prices remained quotably unchanged. Caustic potash was rather unsteady and dealers were quite anxious to shade on actual business. Copper sulphate was in fair demand and producers reported an active call from the agricultural districts. Yellow prussiate of soda, formaldehyde, oxalic acid, cyanide of soda and bichromate of soda and potash continued without any notable changes.

Principal Price Changes

Alcohol—Producers reported a fair business for denatured alcohol and methanol. Second hands quoted rather low on several odd lots, but the general range for methanol 95 per cent in barrels was around $1.23 per gal. Denatured No. 1 was quoted at 38c. per gal.

Ammonium Sulphate—Leading dealers announced an advance on spot material for export. Quotations ranged around $4.15@$4.25 per 100 lb. f.a.s. for prompt shipment. Bulk material at the works was also advanced, with prices around $3.30@$3.40 per 100 lb.

Arsenic—Importers were rather unsteady and quoted fractionally lower prices on actual business. Buyers were not anxious to purchase in quantity lots at present levels and the general tone was only moderate. Quotations ranged around 15@15½c. per lb.

Barium Chloride—Importers advanced spot prices, due to the unsettled conditions abroad and the scarcity of importations. Quotations ranged around $90@$95 per ton.

Copper Sulphate — Producers reported a moderate business to the insecticide industries, with quotations at former levels. Prices range around $6.40 for 100 lb. for regular crystals.

Formaldehyde—Dealers quoted much under producers' prices, due to the unsteady consuming demand. Resale lots were around the market at 15c. per lb. Manufacturers quoted 16@16½c. per lb.

Caustic Potash—Imported material was somewhat lower on spot. Quotations were heard around 8c. per lb. on spot, with shipments at 8½c. c.i.f. N. Y., duty paid. Demand has fallen off considerably.

Carbonate of Potash — Importers were quite firm on spot material and although prices showed no material advances, round lots were very difficult to purchase at the regular quotations. The 80-85 per cent calcined held at 5¾@6c. per lb., with 96-98 per cent at 7½@8c. per lb.

Caustic Soda—The general demand continued quite steady among exporters and quotations for standard goods held around $3.45@$3.50 per 100 lb. f.a.s. Domestic traders reported a very steady market at $3.75 per 100 lb. ex-store. Contracts remained quotably unchanged.

Prussiate of Soda—Dealers were somewhat higher in their views, although actual business was not of any large dimensions. Spot stocks have been diminishing and prices ranged around 19@19½c. per lb. Shipments were around 18@18½c. per lb.

Sodium Sulphide—Spot quotations have been fractionally advanced by leading dealers. Imports have not been coming in at the rate previously noted and surplus stocks are gradually diminishing. Spot prices range around 4¼@4½c. per lb.

Phenol—Producers continued to report a well sold up condition at the works and second hands were not eager to quote any round lots. Some quotations were heard during the week at 50c. per lb. in drums.

Vegetable Oils Advanced

Linseed Oil—Several crushers announced an advance of 3c. per gal. on spot and nearby oil. There were some dealers, however, that continued to quote former levels. Quotations ranged around $1.01 per gal. in barrels for nearby shipments; 98c. per gal. for May shipments and 95@96c. per gal. for June.

Cottonseed Oil—Crude oil at the mills recorded a new advance, with quotations heard at 10¾c. per lb., tank cars, f.o.b. mill. The demand has only been moderate at the present high levels.

Improved Demand Noted in Chicago Market

Firmer Prices Generally Reported—Heavy Buying Would Cause Shortage

CHICAGO, ILL., Mar. 17, 1923.

The demand for heavy chemicals has improved considerably during the past few days and it is reported that while business was not up to desired levels it was far from dull. In regard to prices, practically all items were firm. Potash compounds in particular were exceptionally firm and nearly the entire list showed advances. So far only a few items are really scarce on spot, but even a short period of heavy buying would without a doubt create a shortage in the local market that would force prices to higher levels.

There was a better demand for alkalis during the past week and the market was firm. *Caustic soda* was quoted from spot stock at $3.50 per 100 lb. for the solid 76 per cent material and $4.15 for the ground or flake. *Caustic potash* was very firm, with the general asking price for small or moderate lots 8½@9c. per lb. basis 88-92 per cent. *Soda ash* was in good demand and the 58 per cent light was quoted at $2.25@$2.30 per 100 lb. in barrels.

Alum Demand Satisfactory

Potash alum was in moderate supply and the demand was satisfactory, according to the principal dealers. The iron-free lump was quoted at 4½@5c. per lb. and the powder of a similar grade at 7½@8c. A much better price on the powdered grade could have been had for prompt shipment from the East. *Ammonium chloride*, white granular, was in fair demand and domestic material was available at 8c. per lb. and foreign at 7¾c. *Ammonium carbonate* was quiet, with only small lots available for immediate delivery. The general quoted price was 10½c. per lb., although it was possible to shade this fractionally in some directions. *Barium carbonate* was easy and it was possible to secure supplies at $85 per ton. *Barium chloride* was unchanged in price, with small quantities held for 5½c. per lb. *Carbon tetrachloride* was quiet, with nearly all dealers quoting 9½c. per lb. for large drums. *Carbon bisulphide* was in a similar position and supplies were available at 7@7½c. per lb. *Copper sulphate* was firm with an advance expected. The spot price for small or moderate lots was 6½@6¾c. per lb. *Furfural* was unchanged at 25c. per lb. *Formaldehyde* was quiet, with only small lots moving, and the price was unchanged at 16@16½c. per lb. *Glycerine* was unchanged at 18½c. per lb. for c.p. material in drums.

Phosphoric anhydride was weaker and it was possible to secure supplies at 33c. per lb. in case lots of 1-lb. tins. *Potassium bichromate* was quite firm with most factors holding the price at 13c. per lb. *Soda bichromate* was not so firm and it was possible to do 8½@9c. per lb. for moderate lots. *Potassium chlorate* was firm with only very small lots available on spot at 9½@10c. per lb. *Yellow prussiate of potash* was scarce and spot supplies were held at 41@42c. per lb. The *red prussiate* was not so firm and several factors were willing to take 85c. per lb. for a moderate lot. *Potassium permanganate* was scarce and 22@23c. per lb. for U.S.P. crystals was the best price noted. *Potassium nitrate* was slow, although the spot price was firm at 7½c. per lb. for the imported granular.

Linseed Oil and Turpentine Sluggish

Turpentine was still in poor demand and the price was somewhat lower than that of a week ago. At the close of today's market it was possible to get single drums at $1.47 per gal.

Linseed oil was in a position similar to that of turpentine and the market was a quiet affair. Single drums of the boiled oil were quoted today at $1.05 per gal. and the raw in like quantities at $1.03.

Labor Shortage Limits Steel Industry

Record Production Is Being Adequately Handled by Improved Transportation Facilities

PITTSBURGH, March 16, 1923.

The steel industry is functioning very well as to production. There are no strikes and no disability from transportation. Operation of some units is prevented by labor scarcity, but there is more employment than at any previous time in this movement.

The Steel Corporation's unfilled obligations stood at 7,283,989 tons at the end of February, indicating an increase of 373,213 tons during the month, the largest monthly increase since last September. The February increase represented about 29 per cent of the month's capacity, and taking shipments at 88 per cent, the bookings appear to have been 117 per cent, against 97 per cent in January and 73 per cent in December. The figures are not indicative of the trade current as a whole. In December the independents had relatively lean order books, and inquiry was chiefly for early delivery, the independents accordingly booking the larger part of the business going.

Generally speaking, independents are not booking business for shipment beyond July 1, for a variety of reasons. They are uncertain as to costs and market prices that may rule later, and they are doubtful whether buyers really know at this time what they will need in third quarter. The Steel Corporation's far forward bookings are chiefly in steel for construction jobs, involving little if any uncertainty as to the steel being required.

The turnover in the steel market, on the whole, is lighter. There is much inquiry, but a great deal of the inquiry is not considered by mills. There are now some developments along the line of work being postponed on account of prices, with particular reference to some tentative car buying by Western roads and a building here and there. The tonnage involved is not large, but the trend is significant. There have been practically no developments in the past week indicating that actual consumption will be heavier in the spring and summer than was to be estimated on the basis of conditions as previously known.

Premiums and Prices

Basis prices for finished steel products have not advanced in the past 2 or 3 weeks, and further general advances are improbable. Premiums for delivery may develop, but there is distinct doubt whether the premium market will be large in point of tonnage. There is premium business being done now, but it covers only an almost insignificant tonnage. Bars, shapes and plates remain at 2.25c. as the general basis, with $2 a ton more paid sometimes, and occasionally as much as $7 on plates.

Steel mills having regular customers in sheet bars will make a price of $42.50 for the second quarter, involving a large tonnage. A few consumers have no regular source of supply, and some with regular sources of supply may require extra tonnages. On such business $45 or more will probably have to be paid, there having already been $45 business done on both sheet bars and slabs. Sheet bars are thus quotable at $42.50@$45 and slabs and billets at $45.

Pig Iron and Coke

The buying movement in Connellsville furnace coke for second quarter is now practically ended, with the larger operators well sold up and with substantially all the operating furnaces, such as use purchased Connellsville coke, well covered, together with most of the idle furnaces that are at all likely to get into blast. The business totaled a trifle over 300,000 tons a month. Most of the buying was at $7, with $7.25 done on much of the later business, making an average for the whole tonnage of nearly $7.10.

Basic iron at valley furnaces has followed the advance in foundry iron reported a week ago, from $28.50 to $30, and as was the case with foundry it appears there were no sales at intermediate prices. Bessemer has advanced $1, to $30, so that the three prominent grades are all quotable at the moment at $30 valley. Furnaces are looking for higher prices, however, and some producers are out of the market. Within a week prices may be $1 or $2 higher. The furnaces seem to be comfortably sold for second quarter and it remains to be seen how well consumption is covered. There is no interest thus far in third quarter.

In all probability Lake Superior iron ore prices will be 50c. higher for the coming season, making Mesabi non-bessemer $5.55 f.o.b. dock. Such an advance, moreover, would restore the 1921 schedule and leave prices $1 below those of 1920, the modern high record.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb.	$0 36 –	$0 38
Acetone, drums	lb.	22	23
Acid, acetic, 28%, bbl	100 lb.	3 15 –	3 40

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

HOLT—The Central Foundry Co will immediately commence erection of a new 1-story foundry, 140x365 ft., for the manufacture of cast-iron pipe for heavy pressure service, 2 to 18 in. in diameter Headquarters are at 41 East 42nd St., New York

BIRMINGHAM—A 1-story foundry will be erected at the plant of the Birmingham Machine & Foundry Co., 11th Ave, to be used for the production of iron castings. It will cost about $12,000, exclusive of equipment

California

BAY POINT—The West Coast Chemical Co., 77 O'Farrell St., San Francisco, has leased a portion of the local plant of the Pacific Coast Shipbuilding Co for the establishment of a temporary factory for the manufacture of sulphur specialties as used in the rubber industry, and chemical byproducts A 5-acre tract of land has been secured in this same section, and at an early date it is purposed to commence the erection of a large plant, at which time the temporary works will be abandoned F A. Somers and H. R. Bostwick head the company

FULLERTON—The Orange County Brick & Tile Co., recently organized, has acquired property from the Moore Brothers Sand Co as a site for a new plant for the manufacture of brick, tile and affiliated burned clay products The works will be equipped for an initial production of about 40,000 bricks per day, and are estimated to cost approximately $50,000, with machinery The company is headed by F C Krause, J W. Carmichael and J. J Lilley

SAN DIEGO—The Union Oil Co, Union Oil Bldg., Los Angeles, has acquired property at San Diego, and plans for the erection of a new storage and distributing plant, with initial capacity of about 80,000 gal

REDLANDS The Jones Vinegar Co has tentative plans under consideration for extensions in its plant to double approximately the present capacity. The company is a recent industry, having been operating since last fall.

SAN FRANCISCO—The Banner Refining Co., Kohl Bldg, is arranging for the immediate erection of a new plant in the vicinity of Seattle, Wash., to cost about $175,000. Plans are also being considered for an oil refinery in southern California or Arizona, to cost approximately a like amount.

RICHMOND—The Pacific Sanitary Mfg Co, manufacturer of sanitary fixtures, has commenced the erection of an addition to its plant at California, 5th and Hensley Sts., estimated to cost approximately $150,000, with equipment

Connecticut

BRIDGEPORT—The Contract Plating Co, 725 North Washington Ave., is planning for the installation of laboratory equipment for chemical and other service R J O'Connor is in charge.

WINDSOR LOCKS C H Dexter & Sons, manufacturers of paper products, have taken bids on a general contract and plan for the early erection of a 4-story and basement addition, 54x100 ft., to be used for the most part as a beater department Greenwood & Noerr 847 Main St, Hartford, Conn., are consulting engineers

Illinois

CHICAGO—The Plunkett Chemical Co., 2940 South Park Ave., has purchased property at 35th and Morgan Sts., 116x160 ft, improved with a 4-story and basement building totaling about 60,000 sq.ft., for a consideration of about $100,000, and plans for the immediate establishment of a new plant. It is purposed to remove the present works to the new location, following repairs and improvements in the structure.

CHICAGO—Gutmann & Co, 1511 Webster St, leather tanners, will soon take bids on a general contract for the erection of a 4-story addition to their tannery, estimated to cost $50,000. I. S. Stein, 35 South Dearborn St., is architect.

CHICAGO—The Asbestos Products Co, 220 South La Salle St., has purchased the factory of the General Combustion Co., at 2100 Fullerton St, from L L Mullins, receiver, for a new plant The site aggregates 150x170 ft., with 1-story and basement building, 50x100 ft. The property was secured for a consideration of $41,000. Machinery will be installed at an early date.

Iowa

SIOUX CITY—The Sioux City Brick & Tile Co, 9 West 3rd St, has awarded a general contract to William Klinger, Warnock Bldg, for the erection of a new plant consisting of seven buildings, estimated to cost about $100,000. The main structure, to be used for operating machinery, will be 5-story, 60x80 ft.; the other buildings, all 1-story, will be 44x136 ft., 45x126 ft., 60x60 ft., 38x60 ft., 38x44 ft., and 24x52 ft. Work will be commenced at once D P. Mahoney is president and general manager

Kentucky

CARTER—The Ashland Limestone Co has plans under consideration for the installation of additional equipment at its plant, including power house. The company has a tract of 100 acres of land, and plans for extensive output M. E S Poseg, P. O. Box 668, Ashland, Ky., is manager and engineer

LEXINGTON—The board of directors, State University of Kentucky, has commissioned Coolidge & Shattuck, Ames Bldg., Boston, Mass, architects, to prepare plans for a 2-story and basement addition, 56x110 ft., to the chemistry building at the institution, estimated to cost approximately $80,000. Frank McVey is president.

OWENSBORO—Bolger & Medley have plans in preparation for the construction of a new local plant for the manufacture of brick and tile products, estimated to cost $60,000

Maryland

BALTIMORE—The Maryland Glass Corp., Linden and Ontario Sts, will immediately commence the erection of a 1-story addition to its plant, 40x120 ft, estimated to cost $25,000. A general building contract has been let to the Austin Co., Bulletin Bldg., Philadelphia, Pa.

ELKTON—The Beacon Hill Brick Co, recently organized with a capital of $80,000, is perfecting plans for the operation of a new plant in the Beacon Hill section for the manufacture of brick and tile products Equipment will be provided for an initial working force of about 35 men John Mattiuse and James F. Evans, Elkton, head the company

HANCOCK—The Maryland Glass Sand Co. has plans under way for extensions and improvements in its plant for considerable increase in capacity. It is purposed to electrify the complete works, and equipment for this purpose will be installed. The company has recently arranged for an increase in capital from $150,000 to $250,000 for expansion.

BALTIMORE The Prudential Oil Corp, Fairfield, has taken title to a tract of land, 161x945 ft, heretofore held by the United States Industrial Alcohol Co., for a consideration of $23 500, and will use the site for the construction of a new oil storage and distributing plant.

Massachusetts

HOLYOKE—The Judd Paper Co., 166 Race St, is considering plans for the erection of a new building at its plant to cost about $75,000 George P. B. Alderman & Co., 316 High St., Holyoke, is architect

Michigan

LANSING—The Briggs Co., manufacturer of brick and other burned clay products, with plants at Grand Rapids and Grand Ledge, Mich., has acquired the local works of the Clippert & Spaulding Co., with rated capacity of about 70,000 face brick per day. Immediate possession will be taken and plans developed for increased output. It is purposed to install additional machinery to double, approximately, the present capacity.

DETROIT—Contract has been awarded to the Austin Co., Penobscot Bldg, for the erection of a 1- and 2-story foundry at the plant of the United States Radiator Co., Campbell Ave., estimated to cost $104,000, with equipment. It will be devoted to the production of iron castings.

MUSKEGON—The Central Paper Co. has work under way on two additional buildings at its plant, to be used for general manufacturing. The structures will cost in excess of $50,000.

Minnesota

MINNEAPOLIS—The Diamond Steel Products Co, 1414 Marshall St, is perfecting plans for the erection of a new 2-story plant addition George C Bouthinon is one of the heads of the company in charge

New Hampshire

EAST JAFFREY—The New Hampshire Match Co, Keene, N. H., is arranging for the early installation of machinery at its new local plant now in course of completion It will be 1-story, 50x148 ft and estimated to cost approximately $25,000, exclusive of equipment. L F Dickenson heads the company.

New Jersey

NEWARK—The Eastern Steel Castings Co., a subsidiary of the American Brake Shoe & Foundry Co., 30 Church St., New York, has taken over the plant of the parent company at Ave. L and Edwards St., Newark, comprising three main buildings, 230x480 ft, 60x230 ft. and 60x200 ft, on large tract of land. The plant will be used for the production of steel castings, and will be equipped to develop a total output of 1,000 tons per month The Eastern company recently acquired the plant and business of the Bayonne Steel Casting Co., Oak St, Bayonne, N. J, and will remove this works to the new location. William D. Sargent, formerly head of the Bayonne company, will be president of the Eastern organization

BLOOMSBURY—The Bloomsbury Graphite Co. has authorized the immediate rebuilding of its local plant devoted to the manufacture of graphite products, foundry facings, etc, recently destroyed by fire with loss of about $10,000 New grinding and other machinery will be installed to double the former capacity.

NEWARK—H. F. Sommer & Co, 219 Wilson Ave, operating a leather tannery, will build a 1-story addition to their plant at 12-16 Paris St, including improvements in the present structure, estimated to cost $15,000

BAYONNE—The Tide Water Oil Co., 11 Broadway, New York, has filed plans for the erection of a new building at its local refinery and additional tanks, estimated to cost $25,000.

New York

BROOKLYN—Plans are being completed and bids will soon be asked for the erection of a 2-story addition, 54x100 ft, to the plant of Abraham Werbelovsky, 83 Meserole St., manufacturer of glass products to be located at 57-59 Scholl St.. estimated to cost close to $40,000. Harry J Nurick, 44 Court St., is architect.

BUFFALO—Spencer Kellogg & Sons, Delaware St, manufacturers of linseed, core and other oils, will build a new addition to their plant at Michigan and Ganson Sts, to cost about $12,000. It will be used for general operating service.

NORTH TONAWANDA The Herschell-Spillman Motor Co., Sweeney St, is planning for the immediate rebuilding of the portion of its heat-treating department, damaged by fire March 4. An official estimate of loss has not been made.

North Carolina

FOUR OAKS—The Meadow Brick Co., recently organized with a capital of $25,000, has tentative plans under consideration for the installation of additional equipment of develop a maximum output in excess of 75,000 bricks per day New clay loading machinery will be purchased. J. W. Sanders is president, and W. H. Smith, secretary and treasurer.

Ohio

EAST PALESTINE—The W. S. George Pottery Co. manufacturer of general ware, has completed plans and will break ground at

once for the erection of a 2-story addition, 156x400 ft., on site of the old East Palestine pottery, destroyed by fire some time ago A tunnel kiln will be installed in the new plant, which is estimated to cost close to $300,000, with equipment Facilities will be provided for the employment of about 400 operatives. W. S. George heads the company.

COLUMBUS—H. C. Godman, 35th St, has plans nearing completion for the erection of a new plant at West State and Lucas Sts, to be equipped for the manufacture of leatherboard products. Richards, McCarty & Bulford, 584 East Broad St., are architects.

Pennsylvania

MARTIN'S CREEK — The Alpha Portland Cement Co., Easton, Pa., will make extensions and improvements in its local mill including the installation of a new power plant and waste heat equipment, the latter to provide for more economical operation Other apparatus will also be purchased The company has arranged an appropriation in excess of $1,000,000 for extensions and betterments in its other mills in different parts of the country.

HAZLETON—The Hazleton Iron Works Co has tentative plans under consideration for the rebuilding of the portion of its iron foundry, recently destroyed by fire with loss approximating $50.000, including equipment

YORK The Emigsville Lime & Shale Co, Emigsville, near York, has preliminary plans in progress for the rebuilding of the portion of its plant destroyed by fire March 8. An official estimate of loss of buildings and machinery has not been announced

HILLSVILLE—Fire, March 2, caused by an explosion, destroyed a portion of the Quaker Falls plant of the Grasselli Powder Co, near Hillsville, with loss estimated at $14,000 It is planned to rebuild.

Texas

LUBBOCK—The Lubbock Cotton Oil Co, recently organized with a capital of $150,000, has plans nearing completion for the erection of a new local plant to cost about $100,000, including machinery. Bids will soon be asked. G. A. Simmons is general manager.

SMITH'S BLUFF—The Pure Oil Co., Pure Oil Bldg., Columbus, O. is perfecting plans for the erection of a new refining plant on local site, recently acquired. It will have a capacity of 10,000 bbl per day, and will include a gasoline refinery, with 26 "cracking" process units. It is estimated to cost in excess of $300,000, including machinery.

PORT ARTHUR — The Gulf Refining Co, Frick Annex, Pittsburgh, Pa., has arranged an appropriation of more than $10,000,000 for extensions and improvements in its local oil refinery. The work will include an addition to the main plant, with 94 oil stills; extension to the chloride process department used for gasoline production; addition to the sulphuric acid works to provide a total capacity of about 100 tons per day; new grease and compounding plant, with total floor area of about 100,000 sq.ft.; new power and pumping machinery for different operating departments; new electric power plant of 10,000 kw. capacity and steam power house of 6,000-hp. rating; can manufacturing works and additions to tankage department, the latter including 66 new steel tanks and auxiliary equipment with capacity of 500 000 bbl. The company will also build an addition to concrete wharf. George V. Taber is vice-president in charge.

BRECKENRIDGE—The Acme Brick Co., Fort Worth, Tex., has tentative plans under consideration for the construction of a new plant at Breckenridge. A site is being selected. W. R. Brennt is president.

WACO—The Waco Lime & Products Co., formerly known as the Koury Calcium Co., McGregor, Tex., has work under way on a new local lime plant with capacity of about 100 tons a day. A hydrator and other equipment will be provided for larger output in the near future. John L. Spurlin, Jr., Waco, is secretary.

Virginia

ROANOKE—The Roanoke Tire & Rubber Co, Terry Bldg., has commissioned B F. Mitchell, Seaboard Bank Bldg., architect, to prepare plans for its proposed new 3-story plant in the West End section, 50x130 ft., for the manufacture of tires and other rubber products. Alfred Buck is head of the company, in charge.

West Virginia

NEWELL—The Homer Laughlin China Co. is completing plans for the erection of a new plant unit on the old golf links, Ohio River, to consist of a main 1-story structure, 220x800 ft., estimated to cost in excess of $600,000, with machinery. Three tunnel kilns, Harrop type, will be constructed, one to be used for bisque ware, another for glost material and the third for decorating service Work will be commenced at an early date. Marcus Aaron is president.

PARKERSBURG—The plant of the Parkersburg Brick Co. has been acquired by the Citizens' Lumber Co, consisting of about 10 acres of land in the Lee's Hill section. The new owner will continue the operation of the plant and has plans in progress for the erection of a new works on adjoining site, with daily capacity of about 75,000 bricks, estimated to cost $100,000, with machinery.

Wisconsin

STEVENS POINT—The Consolidated Water Power & Paper Co. has completed plans and will soon break ground for the construction of a 2-story addition to its local mill, estimated to cost approximately $150,000, with machinery. L. A. De Guers, Wood Block, Wisconsin Rapids, is engineer. George W Mead heads the company.

Industrial Developments

LEATHER — The Endicott - Johnson Co., Endicott and Johnson City, N Y., is maintaining capacity production at practically all of its tanneries giving employment to full working forces. The sole leather tannery has a production of over 6,000 sides of leather per day, with employment of 450 operatives; the chrome leather tannery at Endicott has a daily output of 1,500 sides, giving work to 100 persons; the chrome sole tannery at this same place is also giving employment to about 100 workers, under a capacity schedule of 2,000 sides of leather daily; the new upper leather tanning plant at Endicott is employing 200 operatives, with a rated output of 1,800 sides per day, while the other tannery of this same character here is running on a basis of 3,800 sides daily, with employment of 400 workers; the calfskin tannery of the company produces about 5,000 sides of leather per day, with employment of 650 operatives.

Dungan, Hood & Co, Philadelphia, Pa., specializing in the production of glazed kid leathers, are operating at about 75 per cent of capacity.

Tolman, Dow & Co, Inc., Woburn, Mass., is operating at regular capacity at its local tannery, with bulk of output devoted to brown leathers.

GLASS — The Owens Bottle Co., South Glassboro, N. J., is running at the highest capacity possible with existing working force, and is said to be seeking additional operatives. The plant has orders on hand for some time to come.

The Carr-Lowrey Glass Co., Westport, Md, is maintaining production at its local plant, devoted to hollow ware specialties, with full working force, and a recent fire at the works, caused by the bursting of a 20-ton mixing vat of molten glass, will not cause any suspension in operations

The Illinois Glass Co, Bridgeton, N. J., is operating at its new local machine-blowing plant and adding additional workers to the force. It is expected to develop capacity production at an early date.

The majority of the glass plants in the vicinity of Millville, Salem and Vineland, N. J., are operating at capacity, with full working forces, and expect to continue on this basis throughout the spring and well into the summer.

CERAMIC—The Gem Clay Works, Sebring, O, are running at maximum capacity with full working force. Plans are being developed to double the present output and a number of additions will be constructed.

The Elk Fire Brick Co., Renovo, Pa., is operating under heavy production and will maintain this schedule for an indefinite period. Plans are in progress for the establishment of a housing development for employees.

The Wellsville Fire Brick Co., Wellsville, Mo., is maintaining capacity operations and heavy shipments are leaving the plant. A full working force is being employed. It is expected to advance production with the installation of additional equipment, giving employment to an increased number of workers.

The Pennsylvania Clay Co. is arranging for the immediate resumption of operations at its Conway, Pa., plant, devoted to the production of paving brick. It is expected to develop an output of about 60,000 bricks per day. The plant has been closed recently for repairs and improvements.

IRON AND STEEL - The Joseph E. Thropp Co., Inc, Cumberland, Md., recently succeeding to the blast furnace and iron properties of Joseph E. Thropp, has improvement and repair work in progress at the stack, and plans to blow in at an early date. The furnace has been idle for some months past. Operations are also being resumed at the coke ovens and limestone quarries of the company

The Eastern Steel Co, Pottsville, Pa., is advancing operations at its local plant and additional open-hearth furnaces will soon be lighted. Part of the works will be placed on a double turn at once, giving employment to an increased operating force

The McKinney Steel Co., Cleveland, O., has resumed operations at its two furnaces at Josephine, near Blairsville, Pa., following a suspension for about 24 months. It is expected to maintain production for an indefinite period, giving employment to a large working quota The company is planning to blow in its furnace on the Genesee River near Rochester, N Y, early in April, and the stack is being made ready.

E. J Lavino & Co., Philadelphia, Pa, has blown in its blast furnace at Lebanon, Pa., after a suspension for nearly 2 years. This makes the second stack of the company in Bethlhem County in service All five stacks of the Bethlehem Steel Co, in this same county, are still inactive.

The Carnegie Steel Co, Sharon, Pa., is making ready to apply the torch to its No. 4 blast furnace here, after an idleness of about 36 months. With this stack in service, all furnaces of the company will be producing for the first time since April, 1920. Throughout the Pittsburgh district, 49 of the 59 furnaces of the company are now on the active list

Steel mills in the vicinity of Birmingham, Ala., are running at capacity, with full working forces The Gulf States Steel Co., is at maximum output at its Gadsden, Ala., works and has recently advanced the wages of common labor at this plant The American Steel & Wire Co, at Fairfield, is running full.

MISCELLANEOUS - The Hinckley Corp. is arranging for the resumption of operations at its sulphite mill at Hinckley, N Y. The plant has been closed for about 2 years past, and a number of improvements will be made, including repairs to machinery.

The Standard Oil Co is breaking all production records at its refining plant at Whiting, Ind, refinery, and on an average of 40,000 bbl., or 2,000,000 gal., of crude oil, are being handled daily, or about 3,000 bbl. more a day than during the pre-war period of 1917-18.

New Companies

THE SURFIX CHEMICAL Co, Detroit, Mich., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts The incorporators are George W. Stallings, A. F and W. H. Knobloch, 3217 Clairmount Ave., Detroit. The last noted represents the company.

THE LEONARD PAPER GOODS Co, Boston, Mass, has been incorporated with a capital of $100,000, to manufacture paper products, Elbert O. Leonard is president; and Andrew J. Wright, 500 Park Ave., Worcester, Mass., treasurer.

THE PLASTIC PRODUCTS Co, Detroit, Mich., has been incorporated with a capital of $25,000, to manufacture paints and kindred products. The incorporators are Russell S. Collins, E F. and Alfred D. Covert, 1940 Highland Ave., Detroit.

THE CYACO CHEMICAL Co., New York, N. Y., care of Jenks & Rogers, 67 Wall St., representatives, has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are C., I. and A. Juster.

THE DALTON MALLEABLE CASTING Co., Warsaw, Ind., has been incorporated with a capital of $350,000, to manufacture iron and other metal castings. The incorporators are Donald J. and J. S. Dalton, and T. C. and W. D. Frazer, all of Dalton.

THE NATIONAL ART POTTERY Co., Camden, N. J., care of S. Stanger Iszard, 314 Market St., Camden, representative, has been incorporated with a capital of $125,000, to manufacture pottery products. The incorporators are Howard W. Willett, Curtis J. Rothermel and Frederic W. Lineaweaver.

THE MISSOURI GLUE Co., St. Louis, Mo., has been incorporated with a capital of $70,000, to manufacture glue, paste and other adhesive products. The incorporators are Albert Goetz, McCune Gill and T. J Sheridan, all of St. Louis.

Manufacturers' Catalogs

THE WESTINGHOUSE ELECTRIC & MFG CO., East Pittsburgh, Pa., has issued a 20 page booklet, Folder 4506, entitled "Salient Facts on Silent Gears." The booklet describes the advantages of the use of micarta gears and pinions and gives photographs and data describing some of their applications, tables of gear data, etc. This company has also issued Leaflet 1867, which describes electrical equipment for coke plant machinery. Illustrations of the uses of electricity in by-product plants are shown, with recommendations as to the various types to be used.

THE REFRACTORIES MANUFACTURERS ASSN. calls attention to a booklet entitled "Brands Used in the Refractories Industry." It lists the brands used by practically all of the manufacturers of refractory brick and is useful to a man who knows the brand he wants to use, but who doesn't know who makes it. A copy will be sent gratis on receipt of a written request to the association, 810 Oliver Bldg., Pittsburgh, Pa.

THE CHASE METAL WORKS, Waterbury, Conn., has published a very interesting catalog on Chase Condenser Tubes, which describes the technical manufacture and control exercised in making high grade tubing. It illustrates and describes the manufacture of condenser tubes, the steps in manufacture, the properties and specifications, condenser tube service and a list of those who use the tubes.

THE LINK-BELT CO., Nicetown, Philadelphia, Pa., has published a Portable Loader catalog embracing its entire line of portable equipment. Copies can be obtained by addressing the manufacturers. It contains complete specifications of all of the standard machines, which include the one man power swiveling loader, the portable belt conveyor, the standard type "A" machine for anthracite coal, and "CS" loader for handling sand and gravel.

CHALMERS & WILLIAMS, Chicago Heights, Ill., have issued a unique pamphlet in the form of a book, entitled "The 100 a Year Club." It describes and illustrates the Symons disk crushers.

EMIL E. LUNGWITZ, New York, is distributing a booklet on Hanbold Self-Unloading Centrifuge. This centrifuge is built in two styles, either half automatic or absolutely automatic. This booklet concerns itself with the half-automatic centrifuge solely. The absolutely automatic centrifuge is the subject matter of another booklet which will be sent to those desiring it. The half automatic centrifuge will handle such materials as calcium carbonate, calcium sulphate, magnesia carbonate, barium sulphate, barium carbonate, alumina, cyanide slimes, flotation concentrates, starch, short fibers, etc., which at present are handled by the various makes of leaf and rotary suction filters. In addition it is claimed that it will filter fine to coarse crystals of any chemical composition.

F. J. RYAN & CO., Philadelphia, Pa., have issued a bulletin on oil burners for all industrial heating operations. It contains information on the way of determining the amount of air necessary for proper combustion and the correct proportions of air with oil.

SPRAGUE SMITH CO., 162 West Randolph St., Chicago, is issuing a booklet on "Glass and Glazing" which is being distributed by the National Glass Distributors Assn. The object of the booklet is to present to the users of glass a standard or guide for the architect, owner or contractor, by which the material may be better known and more readily understood. It briefly describes the more important and different kinds of glass for building purposes, with regard to adaptability for certain definite uses, and gives printed illustrations. The booklet does not cover every department of structural glass or go exhaustively into the details of the artistic but is confined to the everyday materials which are often thought so simple as to need no consideration.

THE BEACH-RUSS CO., New York, has issued five new pamphlets. No. 20 is on vacuum pumps for vacuum heating systems; No. 25 is on patented gas and oil-burning rivet heating furnaces; No. 26 on high-vacuum finishing pumps. No. 30 is on rotary pumps, and No. 29 is on gas boosters.

THE ESTERLINE-ANGUS CO., Indianapolis, Ind., has issued two bulletins, No. 1122, entitled "How to Make a Plant Survey," and Bulletin No. 1222, on "Instruments for Recording Condenser Leakage."

W. A. JONES FOUNDRY & MACHINE CO., Chicago, Ill., announces catalog 26, on speed reduction drives, which is very elaborate. The information should be of value to consulting engineers, superintendents, chief engineers, master mechanics, etc. It embodies technical and practical information, complete descriptive matter and illustrations of typical drives. The installation section presents pictorially reducer drives in many large industrial plants, and dimensions, weights and horsepower ratings for complete speed reduction sets are shown.

THE ROTO CO., Hartford, Conn., in a new 32-page booklet illustrates and describes Roto tube cleaners, air, steam or water driven, for fire tube and water tube boilers, fuel economizers, condensers, evaporators, feed water heaters, locomotive arch tubes, oil stills, etc.

Industrial Notes

THE OILGEAR CO., Milwaukee, Wis., has opened an office in Detroit, at 115 East Jefferson Ave. Donald Clute, who formerly handled the sale of Oilgear products for the Cadillac Machinery Co., has been placed in charge of this office.

THE COLUMBIA STEEL CORP., San Francisco, Calif., has engaged Freyn, Brassert & Co. as consulting engineers for the construction of its new blast-furnace plant at Provo, Utah.

THE STANDARD CONVEYOR CO., North St. Paul, Minn., announces that it has acquired by purchase all the rights, titles and patents pertaining to the "Brown Portable" line of portable and sectional piling, elevating, conveying, loading and unloading machinery for the handling of packed and loose materials. This line of machinery has been manufactured by the Brown Portable Conveying Machinery Co. at North Chicago for 10 years. Until further notice the plant will be continued in operation by the Standard Conveyor Co., to which all inquiries and correspondence should be addressed. The organization which has developed the portable conveying machinery will continue with the Standard Conveyor Co.

THE MINE & SMELTER SUPPLY CO., with branches in Denver, Salt Lake City and El Paso, has taken over the exclusive representation for Colorado, Utah, Nevada, Wyoming, New Mexico and western Texas for Wilson plastic-arc welders and Wilson color tipt welding metals, for the Wilson Welder & Metals Co., New York City. The Wilson machine and metals were used during the world war in repairing the damage done to a large number of the interned German vessels. Electric arc welding was the method chosen by which the damaged machinery parts of this fleet of vessels were put in operating and seagoing condition and the work was completed within 6 months' time. This machine is also used in railroad shops in the United States and in foreign countries and also by large industrial plants in the United States. The Mine & Smelter Supply Co. will carry in stock at each of its branches a supply of all grades of Wilson color-tipt metals and plastic-arc machines for distribution throughout its territory.

THE CENTRAL STEEL CO., Massilon, O., manufacturer of alloy steel products, has decided to enlarge its field of activities by the addition of special alloy steels for railroad service. This department is under the direction of Irving H. Jones, formerly of Joseph T. Ryerson & Son, Chicago. Mr. Jones will maintain offices in the Peoples Gas Bldg., Chicago, which is the Western headquarters of the Central Steel Co.

The board of directors of the BUFFALO FOUNDRY & MACHINE CO., Buffalo, N. Y., at a recent meeting announced the election of two new officers: C. W. Pearson, who has been associated with the company in various managerial positions for a number of years and for the past year in charge of sales, becomes vice-president and treasurer. In addition to the new duties his promotion will bring, Mr. Pearson will continue as director of sales. P. J. Krentz, who for a number of years past has been works manager, has also been elected as vice-president. As in the past, he will continue actively in charge of manufacture and production. Both Mr. Pearson and Mr. Krentz have been with the company almost from its organization. Their promotions come as no surprise to those familiar with their activities.

THE TH. GOLDSCHMIDT CORP., 15 William St., New York City, has just been founded by the Th. Goldschmidt A. G., in Essen, which years ago also founded the Goldschmidt Detinning Co. and the Goldschmidt Thermit Corp., now united in the Metal & Thermit Corp. The Th. Goldschmidt Corp. represents the Th. Goldschmidt A. G. and its affiliated firms, the Chemische Fabrik Buckau A. G. of Magdeburg, Neufeldt & Kuhnke of Kiel and several other European concerns, for the sale of their products and for the exploitation of new processes and apparatus in the United States and Canada. The president of the corporation is Dr. Franz Meyer, manager of the Th. Goldschmidt A. G., formerly director and officer of the Metallurgical Co. of America, a subsidiary of the American Metal Co., Ltd., and consulting engineer of the General Chemical Co.

Coming Meetings and Events

AMERICAN ASSOCIATION OF CEREAL CHEMISTS will hold its ninth annual convention at Hotel Sherman, Chicago, June 4 to 9.

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va., May 7 to 9.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O., April 28 to May 4.

AMERICAN GAS ASSOCIATION will hold its annual convention the week of Oct. 15 at Atlantic City. An elaborate exhibition of gas making and gas-utilization equipment is planned.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting June 20-23 at Wilmington, Del.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Eastman Hotel, Hot Springs, Ark., April 30 and May 1.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting May 28 to 31 in Montreal, Canada.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

ENGINEERING SECTION of the National Safety Council will hold a mid-year safety conference April 17 in the auditorium of the Western Society of Engineers.

IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 10 and 11 at the House of the Institution of Civil Engineers, London, S. W. 1.

NATIONAL ASSOCIATION OF MANUFACTURERS OF THE UNITED STATES OF AMERICA will meet in annual conference May 14 to 16, inclusive, at the Waldorf-Astoria, New York City.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH) will be held in New York Sept. 17-22.

NATIONAL FOREIGN TRADE COUNCIL has postponed its annual conference from April 25, 26 and 27, to May 2, 3 and 4. It will be held in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

FIFTH PAN-AMERICAN CONFERENCE will be held at Santiago, Chile, March 25, 1923.

SOCIETY FOR STEEL TREATING — Eastern sectional meeting will be held June 14 and 15, in Bethlehem, Pa.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City; March 23—Society of Chemical Industry, regular meeting. April 20 — Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8 — American Chemical Society, regular meeting.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 — New York, March 28, 1923 — Number 13

The Top Of the Hill

ANY one who has driven an automobile knows that an approach to the top of a hill at high speed on the wrong side of the road is dangerous. In the business world the same thing applies, and several traffic officers have stationed themselves on the business hill which has been climbed so rapidly and successfully during the past 18 months, warning traffic to keep to the right and to travel at a reasonable speed. These three officers are no less important persons than the Secretary of Commerce, the vice-president of the National City Bank, and the Federal Reserve Board.

Business always drives a strange road. No one can foresee, especially when on the upgrade, what will be over the top of the hill. In fact, long-time business forecasts are always impossible because the fog on the road conceals everything over a few weeks, or at most a few months, ahead. When we are going down hill we always know that there will be an upgrade when the bottom is reached. On the downgrade the brake pedal and the brake lever are vigorously used, especially if the grade be steep; but on the climb, business is inclined to "step on the gas" and go as fast as possible in the hope that higher levels of business may produce wide and pleasing views, green with the currency of large profit.

Right now clear-thinking business men who view the national situation broadly see that the high speed in increase of business forecasts an arrival at the top under conditions that may not be altogether safe. The top will be reached inevitably with a limit of the buying and consuming power of the public, supplemented by such exports as disturbed foreign conditions may permit. Careful appraisal of the situation indicates that the top of business activity is not very far ahead. The sign "Go Slow" is, therefore, a very important warning.

In two cases the warnings referred to above have been against excessive building activity. The Secretary of Commerce urges that the federal, state and municipal construction work now going forward actively be postponed somewhat in order that it may be used to fill in the hollows that inevitably will come later. This sort of leveling up of the business highway is an untried method of road grading, but it may prove to be a highly satisfactory one. The Federal Reserve Board evidently thinks well of the Secretary's proposal, for it too is contributing to the same end by delaying construction work under its control. Inevitably this will react upon banking agencies of all sorts, who will hesitate to finance additional construction unless it is very clear that it is imperative and that it can be done without unduly high costs.

The third traffic officer who has just placed himself on the business highway speaks from a prominent position as a representative of the Chamber of Commerce of the United States. This eminent banker would extend the warning against excessive construction work to include caution against excessive business inflation and undue expansion of credits in all lines.

When business comes with comparative ease, there is a great temptation to work one's credit facilities to the limit. However, the lesson of the disastrous consequences of that policy, as practiced in 1919 and early 1920, are still too clear in the minds of business to be forgotten. Business confidently expects that as the top of the grade is reached, it will be found that it is a plateau of successful and stable business which has been reached, not simply another sharp peak in the up and down of the business cycle.

If all branches of business will travel on their own side of the road and keep the pace of the crowd, there is no reason to believe that they will not arrive safely at the crest. But spurting ahead, especially attempting to pass just before reaching the top of the grade, will be bad practice.

The Power Outlook And Chemical Industry

THE power supply situation is certain to undergo great changes during the next decade. These changes, foreshadowed last year in the Superpower Survey, are well evidenced by the fact that the largest electric service corporations are studying all the available sources of hydro-electric generation, with a view to supplementing the output of their steam-electric generating plants with power made from "white coal."

The underlying reasons for this tendency are several. Outstanding is the well-recognized difficulty of providing transportation facilities for moving much more coal than the amount now consumed. Then again, the recent difficulties with labor in the coal fields make every coal consumer doubtful of the future continuity of fuel supply. Finally, the recent survey of the Bureau of Mines predicts the exhaustion within the next 50 years of all the good grades of steam coal mined in the eastern United States. This last is of great importance to all, for to raise steam with low-grade coal greatly increases the cost, and it is seldom economical to transport such coal any appreciable distance.

The recent widespread agitation for the development of the power of the St. Lawrence and the interest that New England manufacturers are taking in the development at La Grand Décharge at Lake St. John show where the public and most manufacturing interests look for relief from this coal situation. As predicted in the Superpower Survey, most electric power in the not distant future will be taken from long-distance high-tension transmission lines, fed from hydro-electric

plants, from the most favorably situated of the present existing steam-electric plants and from new steam-electric plants located at the mine-head.

The manufacturer in the chemical line may not see at first glance how these facts will affect him. The large needs of some chemical plants for process steam will undoubtedly make it economical for them to burn coal long after all other manufacturers have found it wise to resort to central station service. In fact, with the recent development of bleeder turbines, it may never be of financial advantage for such a plant to cease the use of coal to generate steam.

However, in many localities in Canada, such as Montreal, Three Rivers and St. Johns, and also in France, Italy, Switzerland, Norway and Sweden, it has been found worth while to generate steam by the use of electric-steam boilers. This because coal is difficult to get and is expensive, and there is a ready supply of high-tension current which can be cheaply had, especially at off-peak load periods.

It would be advisable for users of process steam in this country to investigate the methods used and the results obtained in Canada. For with the prospective development of high-tension distribution in this country, they may find it advantageous to follow the foreign example and place their full dependence on central station power.

A Wake Or Awake?

WHEN a gathering of technical men holds several simultaneous sessions, as is the habit of the American Institute of Mining and Metallurgical Engineers, it is obviously impossible for one person to attend all of them and appraise the relative interest manifest in the various subjects. However, the writer of these lines did sit through the recent sessions of the Institute of Metals Division (devoted to non-ferrous alloys) and those of the Iron and Steel Section. At the end of the meeting he could not help wondering, "What is the matter with the steel men?"

Looking back through the old volumes of *Transactions* you can find metallurgical classics from the pens of FRITZ, HOLLEY, HUNT and GAYLEY. Then after the mechanical revolution of 30 years ago came the interest in quality metals, exemplified by the new science of physical metallurgy. The keenest students turned their attention to this and during the decade from 1910 the *Transactions* bristled with micrographs and expositions of principles of heat-treatment by HOWE, SAUVEUR, JEFFRIES and BURGESS. Now the leader of these men has passed from us, the others have enlisted their interest in other societies or are publishing through more congenial channels. At any rate, any one having a lively remembrance of the discussions on "flakes" 5 or 6 years ago, a discussion which lasted all morning and broke out afresh and usurped a whole afternoon's program, views with sinking heart a meeting before which was dragged a specification for pig iron—already considered at length by other more interested organizations—and a resurrected paper on merchant bars, written from the 1900 viewpoint.

Of course it is unfair to expect an industry continually to put forth epoch-making ideas and improvements. Perhaps the steel industry has shot its bolt. But the American Society for Steel Treating continues to grow vigorously and hold monthly meetings in thirty different places. And in the Institute itself a smaller group of men, representatives of the poorly organized industry made up of hundreds of little brass and bronze foundries overloaded with hoary traditions and archaic methods, is able to maintain interest and even prepare a feature program.

The life seems to have gone out of the steel men. To see them sit around, after the best fashions among manufacturing chemists, with trumpets to their ears and padlocks on their lips, one would think that they have either reached the summit of absolute perfection or that they have no ideas whatever. Even when an excellent and suggestive paper on dirty steel is read, their silence is intense. One might imagine they had never seen such an animal, or if they had, had promptly nailed its skin on their barn door.

"We protest," say the steel men, "that our silence should be so interpreted. We are experimenting continually, and considering ways and means to improve our product. We have conference after conference for just that thing." But isn't it about time you were getting together in some sort of organization, somewhat extraterritorial? where the men from the big plants can rub elbows with those from the little independents —swap ideas and devise ways and means of warding off the demands of these pestiferous steel treaters, even if it is necessary to find out how to give them what they want. "Why, you know that 6 months ago a man in New England started to investigate his tool failures with hot acid, and today a fellow as far away as St. Louis is demanding 'hot etch' in his specifications! This thing has got to stop!"

Well, get together and stop it. But between you and me, it will not be stopped by a conference in the Carnegie Building, one of those meetings at the Commodore Hotel where Judge GARY rises and says "Gentlemen, I see no reason to doubt the future," or such a wake as the recent A.I.M.E. steel session.

Have You Obtained Your Engineer's License?

NO MATTER what one may think of the policy of licensing professional engineers, the fact remains that over half of the states have laws now on their books requiring that such licenses be obtained. In some states these laws are already in operation. In others the date on which they become operative is not far off. In New York State, for instance, the law takes effect May 5, 1923; and after that date no engineer may engage in the active practice of his profession unless he is licensed.

In view of the almost universal lack of knowledge of license laws among engineers we are printing elsewhere in this issue a résumé of license conditions in twenty-five states, together with the sections of the New York State laws that are of greatest interest to those about to apply for license. In this connection, the New York State law is among the most severe in requirements. Many other states accept the same or lesser qualifications as evidence of fitness to practice. Between many states there is reciprocity so that engineers licensed in one state may practice in another without obtaining a new license.

We advise those of our readers who are soon to be affected by these laws to read over the requirements of New York State carefully and then take care of this new obligation lest neglect should interfere with the conduct of their work.

Co-operation on Industrial Alcohol

A GROUP of representatives of the chemical, drug and related industries interviewed the Commissioner of Internal Revenue recently regarding industrial alcohol. The serious problem imposed upon industry by the restriction of this much maligned industrial chemical was clearly set forth, and the Commissioner was asked to establish a separate industrial alcohol unit in his bureau or, as an alternative, to appoint an advisory committee to assist in formulating rules and solving problems.

A very happy solution is now in sight. Commissioner BLAIR tentatively accepts the idea of a committee of ten members to work with his bureau. It will include wholesale and retail druggists, manufacturers of flavors, extracts, toilet goods and pharmaceuticals, chemists and business men acquainted with the problem from the point of view of both producer and user.

The appointment of such committee in the very near future seems assured. It is to be hoped that nothing will delay its appointment and its aggressive effort to straighten out the present snarl. A mutual understanding certainly could clear the atmosphere of much of the sulphurous language which has been incited by past proceedings.

The Civic Aspect Of Chemical Industries

CITIES in this country have been growing like weeds for the past 10 years. Most, if not all, have grown faster than is good for them; too fast to allow for the proper planning for beauty, for wholesome and economical living, and for the general welfare of their citizens.

Of the hundred cities that have grown most rapidly during the decade from 1910 to 1920 it is reported that increase in population has been principally due to the following causes: 13 on account of the automobile industry, 8 to the discovery of oil or gas in the neighborhood, 10 are suburban towns drawing their people from the overflow of larger cities near by, 18 to iron and steel, 7 to climate, hotels, boarding houses and facilities for health recovery and for amusement, 10 to cotton and cotton manufactures, 9 to the production of foods, 8 to lumber, and 17 attribute their rapid growth to reasons that are indicated as "scattering."

Although the production of iron and steel and the preparation of foods are essentially chemical industries, they are not generally so classified, and for the purpose of our thesis we shall confine ourselves to those industries generally recognized as chemical. What is it, then, that chemical industry does for the community in which it establishes itself? Of all the cities mentioned in the census report Wilmington, Del., is probably the only leading chemical producer among those recorded as "scattering," and we must bear in mind that during the war Wilmington was also very active in shipbuilding.

Chemical industries do not employ a large number of laborers in proportion to the capital invested or the value of the output. It is rare indeed that as such they add largely to the population of a town. And yet, of all the larger producing organizations, the manufacture of chemical products calls for the greatest proportion of technically trained men; of professional men as distinguished from business men and laborers. Aside from a few rustlers in the yard group, most of its laborers also need skill and intelligence. In other words, chemical industry does not often bring to town a vast number of hungry mouths to be fed. But it may, it often can and frequently does, bring *quality*. It brings a considerable influx of professional men, and these, with their scholarly training, are peculiarly desirable as citizens. Skilled workmen are also far more desired as citizens than so-called ordinary laborers.

So much for the advantages. The drawback is that too many chemical concerns maintain dirty backyards; some are offensive in general appearance, and not a few produce noxious fumes and odors as well as unsightly and often destructive wastes. Whenever it is possible to avoid these defects, chemical industry, properly administered, assumes a new civic rôle. With a clean, pleasant-appearing establishment that does not offend, with its large staff of professional men in control and research, who constitute a rare social asset, and its reliable and skilled workingmen, who contribute to the solidity of its people, a city is singularly fortunate in being the home of such an industrial organization. It gives it unusual attraction as a dwelling place. It does far more, in the long run, than the discovery of gushing oil wells in the neighborhood with the sudden millions, the inevitable gamblers, the cheap and short sports, and the collapse that is sure to follow the boom.

Chemical industry sometimes is and oftener may be the contributor of quality, of distinction, of straight thinking and of intellectual life to the city of its domicile.

More Complete Census Information

IN THE past the Census Bureau has reported its statistics on wood distillation in such form that one could not distinguish between the yields from hard and from soft wood. Recently a vigorous objection to this was voiced by one member of the industry and the matter was brought to the attention of the bureau by the editors of *Chem. & Met.* It proved to be a very simple matter to make an arrangement whereby these statistics can be divided to show the two branches of the industry separately.

There are doubtless other interests having similar difficulty with official reports. It is not always easy to use published data, valuable as they are. On the other hand, it is not always easy for the government statistician to understand the needs of industry. At all events, it is highly desirable for the industry and the investigators of such bureaus to understand each other most fully.

In discussing this particular detail with the Census it was found, as might well be expected, that the officials are very anxious to give the maximum possible service to the industries. The bureau obtains inadequate appropriations for some of its work, especially in the Census of Manufactures. But despite this condition, which is chronic with most government offices, the bureau reflects admirably the desire of Secretary HOOVER to make his department a real servant of business. *Chem. & Met.* has frequent occasion to confer with government officers and we find them almost invariably entirely reasonable and approachable. They cannot accomplish the impossible, although they are often in a position to do far more for an industry than is being done if they only know what is wanted.

Readers' Views and Comments

Magnesia as a Polishing Agent

To the Editor of Chemical & Metallurgical Engineering

SIR:—I should like to correct the misleading impression that one is likely to get from reading your article on "Magnesia as a Polishing Agent," page 441, March 7, 1923, which states that Dr. Rosenhain originated its use.

In my article on "Polishing Aluminum and Its Alloys for Metallographic Study," I gave credit to Hanson and Archbutt for introducing its use for polishing aluminum, because they made the first mention of it that I found in the literature. However, anyone reading the reference that I gave (*Inst. of Metals*, vol. 21, No. 1, 1919) would find in the discussion that Dr. Rosenhain stated that he had used the powder about 15 years previous, and would thus readily concede the distinction to him.

The Nature Of Solid Solutions

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the article entitled "The Nature of Solid Solutions" which appeared in the Jan. 3 number of *Chem. & Met.*, a discussion of the crystal structure of the gold-copper solid solutions was introduced. Due to an error in computing atomic per cent from composition by weight, the inference was drawn that the alloys were more dense than their weighted atomic volumes would indicate. It was suggested that some extra attraction existed between unlike atoms which caused the

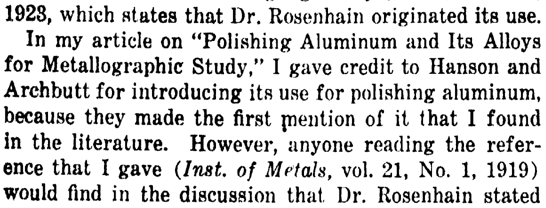

FIG. 1—SIZE OF FUNDAMENTAL CUBE IN THE COPPER-GOLD SOLID SOLUTION SERIES

dimensions of the unit cube of the atomic structure to be less than the atomic proportion would demand if no inordinate compression took place.

Recalculation of the atomic composition for the several lattice measurements produces the straight line function in the plot shown herewith which replaces Fig. 4 of the article. Copper-gold alloys therefore are like the copper-nickel, gold-silver, tungsten-molybdenum and other continuous solid solution series, and do not exhibit the overcompression of the solid solutions of pairs of metals which show limited solubility with formation of intermetallic compounds such as copper-zinc, copper-tin, copper-aluminum, silver-zinc and silver-cadmium.

It appears that the properties of the atoms which enable them to form intermetallic compounds also cause this attractive force when they are organized in the space-lattice of the solvent metal as well as in the compound lattice. And those pairs whose members are chemically similar and without what is sometimes called "chemical affinity" form the continuous solid solutions with no unexpected lattice shrinkage.

Intelligence Tests For Intelligence Testers

To the Editor of Chemical & Metallurgical Engineering

SIR:—You have recently devoted a little space to the consideration of educational matters, particularly the education of engineers, a subject naturally leading to the question, "What is an engineer?" You have also attacked that problem, at least to the extent of deposing and saying that to the best of your knowledge and belief the man who drives the boss to his work in the morning is not an engineer.

Perhaps, therefore, you will permit the observation that a neat definition of "engineer" and the widespread misuse of the word will neither be found nor prevented (respectively) until the officers of our technical schools, where "engineers are made," as it is said, make up their own minds on what is an engineer and what constitutes engineering. I have documentary evidence indicating this state of affairs, taken from the January number of the *Bulletin* of the Society for the Promotion of Engineering Education. Their committee No. 22, on intelligence tests, commenting on "the fact that the engineering profession is losing its identity," writes as follows:

"If a boy fails in machine design and in mathematics he may still become an engineer. It is only necessary for him to declare that he is a commercial engineer, a human engineer, that he can 'engineer' something that is non-technical. Suppose that a boy is considering engineering as his life work and that he has never had any interest in mathematics, physics, mechanics, machines, electrical devices, and tools. Should we advise him to stay out of engineering? That is a very real question. The boy might succeed in engineering anyway by choosing a course in administrative engineering. He does not need to worry about machine design and mathematics, because he is going to train himself to be a leader, the chief who *merely dictates to the ordinary engineer* what is to be done. [The italics are mine.] He wants to be the kind of engineer who is a leader in industry, not the ordinary kind of engineer who invents and designs and who solves problems that are scientifically intricate. He also has the option of becoming a sales engineer, with emphasis on sales. What can the vocational counselor do with such wonderful possibilities?"

What, indeed? I am dumb in the face of these overpowering thoughts!

Suppose a boy—your boy—on reaching college age was color blind, was a crack rifle shot, would go to sleep at a concert, was nauseated by interpretive dancing, could ski like a Norwegian, abominated Ben Hecht

and spent his spare time making puppets and breeding puppies. Should we advise him to stay out of art? That is a very real question, Mr. Editor!

If you were to ask my opinion, I should say that he certainly should by all means be an artist! One of that kind who spend from 10:30 to 1 o'clock in the Seventy-fifth National Bank behind the desk labeled "Chairman of the Board." A sort of sales artist, if I may coin the word, with emphasis on the sales. Let him be a leader, the chief who merely dictates to the ordinary artist what is to be done. Let him be *the leader*, not the ordinary kind of artist who communes secretly with the wise and beautiful and good, absorbs them into his soul and pours forth a vision of loveliness unthinkable, spreading its effulgence on this sordid world throughout the ages, and enrapturing all beholders with its majesty and godliness!

What can the vocational counselor do with such wonderful possibilities? My suggestion, Mr. Editor, is that they try to invent some intelligence tests for intelligence testers! MARTIN SEYT.

The Purposes Of a Standard

To the Editor of Chemical & Metallurgical Engineering

Sir:—Apropos of your editorial "The Purposes of a Standard" it occurs to me that as far as heavy chemicals are concerned the following points are worthy of consideration:

(1) Fixed standards will enable the buyer and seller to know they are talking about the same thing.

(2) Such standards should be an evolution inasmuch as they should arise from existing practices.

(3) In so far as the standards themselves are concerned they should not do more than record a specification. The improvement of specifications should arise from normal business. Enthusiastic people often write ideal specifications which unduly raise the prices of commodities. We have an example of this in the high candlepower standard of gas in the city of New York.

(4) Many individual specifications at the present time are somewhat, but not very far, different from a number of others. These differences might be brought together and such a movement would result in simplicity.

New York City. WALLACE P. COHOE.

Brittle Steel Evaporating Pans

Dr. T. Swinden read a paper before the Birmingham Metallurgical Society recently on "The Embrittling Action of Sodium Salt Solution on Mild Steel." As reported in *Engineering*, he stated that this type of failure was quite distinct from ordinary rupture arising from stressing beyond the normal static strength, or the fatigue type of fracture due to repeated or alternating stresses causing slip within the crystals. The embrittling action of certain salt solutions on mild steel was similar to the action of mercury and ammonium salts on stressed brass causing what was now generally known under the term "season cracking." The particular problem under discussion was the failure of mild steel plates forming the base of large evaporating pans operating upon mixtures of sodium and potassium nitrates. Whereas these pans lasted for many years without any abnormal failure when evaporating brine, trouble was immediately experienced when the nitrate solution was substituted for brine, and the failures were a matter of vital importance during the war period. Experiments showed that a steel plate laid loosely on the bottom of the pan was not deteriorated, while similar plates riveted in the pan in the ordinary way cracked. It was obvious, therefore, that stress was a necessary factor. However, since the action of nitrates was so distinctly different from that of chlorides, it was suggested that selective chemical action was the fundamental factor in producing "season cracking" in mild steel. The analogous case of the action of sodium nitrate was already well known. The speaker suggested that the embrittling action was due to an absorption in a state of solid solution of nitrogen or oxides of nitrogen from the nitrate solution by the material forming the intercrystalline boundaries.

Tin Ore Deposits

Tin is a difficult metal to mine and the known supplies in the world are limited. According to a report made to the Board of Trade, the output from the large alluvial fields of the Federated Malay States, which amounts to 30 per cent of the world production, has already begun to decline. In the Dutch East Indies and in Nigeria, supplying respectively 15 and 4 per cent of the total output, no expansion of the alluvial deposits is considered probable. Siam and China produce about 8 per cent respectively of the world output, but no large increase is looked for in either country.

Bolivia is the only tin-producing area besides Britain where a large output is obtained from lode mining and increased output there is dependent upon the price obtained for the product. Bolivia produces approximately 20 per cent of the total output of tin. Britain's contribution of metallic tin to the world's supply is under 5 per cent and is smelted from ore found in Cornwall and the adjoining part of Devonshire. Most of the mines, however, are faced with a decreasing yield from the ore mined and the position can be retrieved only by the discovery of new bodies of ore, which is possible but likely to be expensive.

El Dorado Oil Field in Arkansas

In a report recently issued by the United States Geological Survey, the results are given of an examination of drill cuttings from one of the wells in the El Dorado oil field. The examination enabled the geologists engaged in the work to subdivide the formations above the producing sand into ten zones, which can be distinguished by carefully watching the drill cuttings as the drilling progresses, so that the approximate position of the bottom of the hole with respect to the oil sand can at all times be known.

The lines of separation between certain of the zones are sharply marked. When the drill passes from the bottom of the Wilcox into the top of the Midway formation it goes from very sandy beds into beds that are only slightly sandy. The point of contact between the Midway and the Arkadelphia formation is also sharp and is easily detected, for at this point the drill passes from beds containing much sand and some limestone into beds that consist dominantly of shale or gumbo. The contact between the Wilcox and the Midway must be carefully noted, for oil or gas may be encountered anywhere below it, and a constant lookout for showings should be maintained after the Midway has been reached.

Casehardening Plant Timken Roller Bearing Co.

Timken Hardens Over Two Million Roller-Bearing Parts Daily —Special Furnaces and Quenching Machines—Slow, Mild Carburizer Used Exclusively—All Pyrometers of Platinum Wire—100 Per Cent Hardness Inspection on Cups and Cones

By E. W. Ehn
Metallurgist, Timken Roller Bearing Co., Canton, Ohio

IN THESE days when everybody owns an automobile of some breed or color—or cherishes a fond hope to buy one as soon as he can obtain the necessary credit —it is perhaps unnecessary to say very much about the way a roller bearing works. Bearings of this kind are found in every part of a modern automobile, front and rear wheels, differential, transmission, pinions, steering pivots, etc. It is not the intention here to enter into a discussion of the relative merit of the different types of roller bearings, or compare them to ball bearings, but in order to describe the metallurgical problems encountered in the manufacture of bearings it might be well to give a short description of the bearings. A typical Timken bearing is constructed as shown in Fig. 1. It consists essentially of an inner race or "cone" *A*, which slips tightly over the shaft, also an outer raceway, or "cup" *B*, that fits tightly into the wheel or bearing box. Placed between these two are a group of tapered rollers, *CC*, varying in number with the size of the bearing, properly spaced in a loose-fitting cage, *D*. By designing the cups, cone and rollers so that the apexes for the different surfaces coincide and fall on the center of the shaft, a true rolling contact is obtained without any sliding motion between the different members of the bearing. Ordinary tapered bearings will, therefore, carry a load on a line contact and will be able to take up a considerable thrust-load in addition to the normal load. By varying the angles the capacity for taking thrust-load and normal load can be regulated at will and suited for different applications.

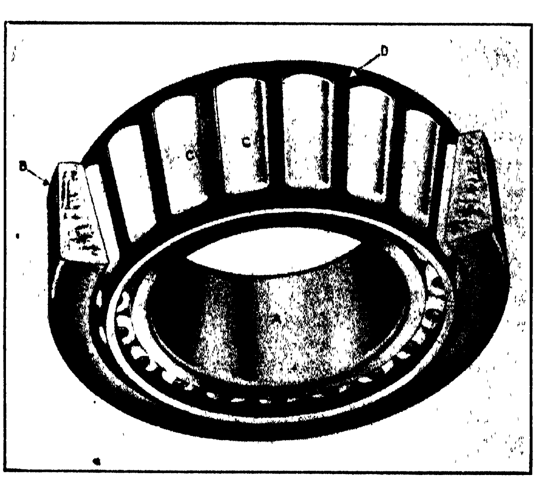

FIG. 1—ASSEMBLY OF TIMKEN ROLLER BEARING

Disregarding the cage, which will not be considered in this outline, all the cups, cones and rolls are made of casehardened low-carbon chromium steel of the following analysis:

	Cups and Cones Per Cent	Rolls Per Cent
Carbon	0.15 to 0.20	0.15 to 0.20
Manganese	0.45 to 0.60	0.45 to 0.60
Sulphur	Below 0.040	Below 0.040
Phosphorus	Below 0.040	Below 0.040
Silicon	0.15 to 0.20	0.15 to 0.20
[illegible]	0.40 to 0.60	1.00 to 1.20

The superiority of the steel is not wholly due to the analysis of the steel used, but is also due to the electric furnace process employed for its making. The Timken plant includes a complete steel mill for making all tubes, bars and rods necessary for the production of the bearings. Steel is made in four 6-ton Heroult furnaces, and the fact that day in and day out the same steel is manufactured permits the workmen to become thoroughly proficient and to have a thorough knowledge of the requirements that must be met.

Laboratory tests, coupled with experience with more than 70,000,000 Timken bearings in service on all types of automotive apparatus and in mechanical and industrial machinery, prove that a bearing made from open-hearth steel will not give the performance and satisfaction of one made from a steel produced by the electric furnace. To prevent misunderstanding it must be mentioned that no claim is made that all open-hearth steel is bad. From time to time when making open-hearth steel, some heats will be as good as electric furnace steel, but for consistently good quality no steel can beat properly made and thoroughly deoxidized electric furnace steel.

Steel is made in the Canton plant from specially selected and analyzed scrap—50 per cent heavy scrap and 50 per cent turnings. After melting down, a test for carbon is made, and if too high some mill scale is added. The first, or dephosphorizing slag, is then rabbled off, the bath recarburized if necessary by coke, and the finishing carbide slag made up. Final adjustments of carbon and manganese are made by adding pig iron after the laboratory analysis has been received. Silicon additions are then made as indicated by forge tests, the furnace is tilted and the steel cast in molds about 5 ft. long and 16¾ in. square, set big end up and having a hot top. Special care is taken to insure a good surface on the ingot—the mold is washed with a solution of molasses and aluminum powder, the ingot remains undisturbed for 1 hour and is then [illegible]

alongside the soaking pits, kept upright, and stripped only when ready to charge.

Ingots are forged into 8-in. blooms in a 625-ton press, cropped, cut in two and cooled. After chipping surface defects they are heated and rolled into useful sizes in a three-high 22-in. bar mill having tables which not only tilt but act as transfer tables as well. Bars from this plant are stock for automatic machine tools and forging machines. Some of the round bars are reheated and pierced in a Mannesman mill, and drawn to size for the caps and cones.

It will be noted that rolls contain a higher chromium content than the cups and cones. It will also be shown that the rolls are double treated after carburizing, as compared with a single quench for the cups and cones. This difference in practice is due to the fact that the rolls in a roller bearing, as well as balls in a ball bearing, must be the strongest part in the bearing. The experience with bearings on the road for more than 20 years, and with tests that have been conducted over a period of 10 years, show that if a bearing is overloaded, failure in service or in test will always be by failure of the rolls. If it were possible to make a better roll, it would consequently be possible to make a better bearing. Some years ago, when nickel steel was being used for rolls with more or less indifferent results, experiments were conducted by the Timken Roller Bearing Co. extending over 3 years and including thousands of bearings, both in the laboratory and on the road, in order to determine definitely the best steel for this part. A large number of steels were tested—chromium-nickel steels and nickel steels of varying percentages of chromium and nickel, tungsten, molybdenum and vanadium steels. Results clearly indicated that the high-chromium steel (1.0 to 1.2 per cent), such as used today in our bearings, was to be preferred to the chromium-nickel steels sometimes suggested for roller bearings. It also confirmed the standard practice in making ball bearings. High-chromium rolls showed the best resistance to wear, fatigue and shock of all the steels that were tried.

Test for Quality

It is outside the scope of this article to discuss the metallurgical details underlying the production of steel, interesting though such an account would be. Every 6-ton heat from our electric furnaces is checked for chemical analysis. In addition, tests are made on the suitability of the steel for casehardening purposes. This method has been developed at the Timken plant and has been the subject of several recent publications.[1] By means of tests of this kind it is possible unerringly to pick out a heat of steel which, while fulfilling all physical and chemical specifications, will possess a tendency to form "soft spots" in hardening. The tests are based on microscopical examination of carburized specimens and a special laboratory outfit working as part of the regular inspection is supplied for this work. Its success has been complete and similar tests are now used at a great many other factories doing considerable carburizing.

The different operations for conversion of the ingot in the steel mill into the proper sizes of forgings, tubes, hars and rods will not be described further. It is sufficient to state that the finished pieces, after proper inspection for size and physical defects (such as seams or laps), are moved to storage racks and from these delivered to the bearing factory according to requirements. By having the steel mill close at hand and subject to orders from the bearing factory, intimate contact and co-operation is maintained—a factor of extreme importance, as it facilitates not only a close control of the raw material for the bearings, but also makes it possible to produce on short notice any tube or bar required for special rush orders.

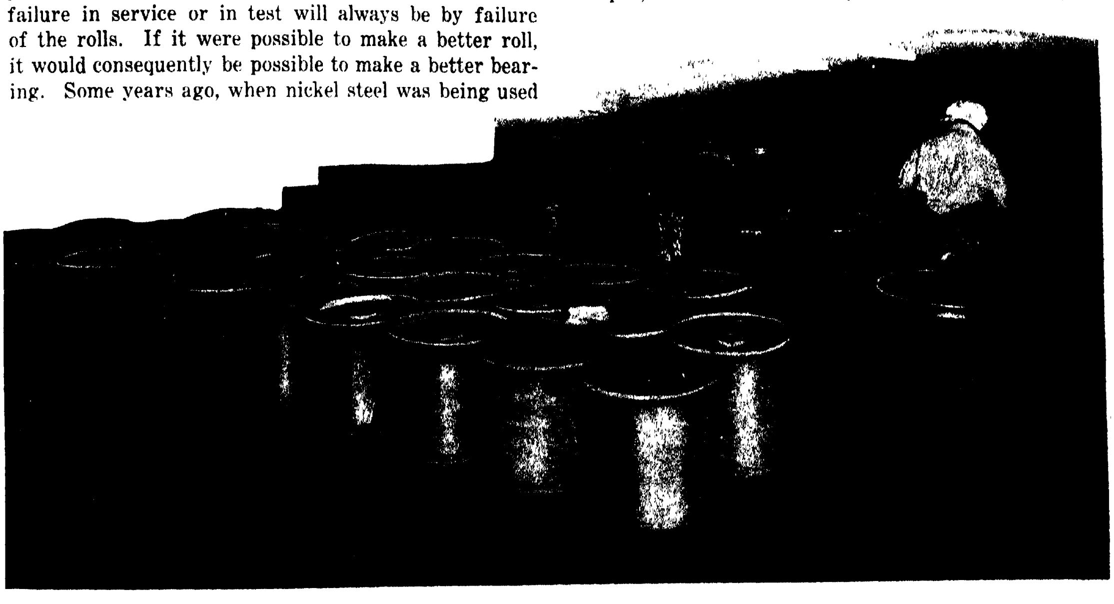

FIG. 2—A CORNER OF THE PACKING ROOM

After the various machining operations in the bearing factory, the "green" cups, cones and rolls are inspected for size, taper and finish, and flow in a steady stream to the carburizing department. The work arrives in properly tagged baskets and pans, and are trucked directly to the packing floor (Fig. 2).

Parts are packed in Nichrome containers with E. F.

[1]"Effect of Quality of Steel on Case-Carburizing Results," by H. W. McQuaid and E. W. Ehn, *Trans.* A.M.E., vol. 67, p. 341 (1922), abstracted in *Chem. & Met.*, vol. 28, p. 656; "Influence of Dissolved Oxides on Carburizing and Hardening Qualities of Steel," by E. W. Ehn, British Iron and Steel Institute, May, 1922, meeting; "Irregularities in Case-Hardened Work Caused by Improperly Made Steel," by E. W. Ehn, American Society for Heat-Treating, 1922, p. 1177 (September issue).

Houghton & Co.'s hydrocarbonated bone black, a compound composed of charred animal bones, charged with a hydrocarbon oil. Every carload of meal is checked before being released for production by special tests under operating conditions and the results must conform to rigid specifications. This compound is a carburizer of the slow type, nearly free from energizing chemicals and with a rather small grain size as compared to most other carburizing compounds. When dry or mixed one part new to three parts old, it flows very freely, which facilitates the packing and dumping of the pots to a considerable extent. The compound is rather heavy as compared with most other compounds, weighing 40 to 45 lb. per cubic foot, and has a comparatively slow heat penetration, but has, on the other hand, several advantages that offset these undesirable features. Shrinkage, even after 50 to 60 hours at heat,

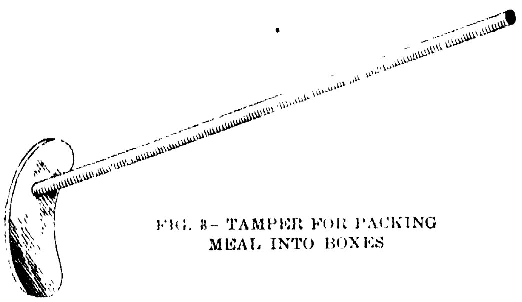

FIG. 3—TAMPER FOR PACKING MEAL INTO BOXES

is negligible and the compound retains its carburizing power practically indefinitely. On account of the slow penetration of carbon into the steel the danger of obtaining hyper-eutectoid cases is eliminated, a matter of extreme importance in the manufacture of roller-bearing parts, where an excessive amount of carbon in the surface would result in its chipping or flaking away and failure of the bearings would quickly result.

Most carburizers are of the rapid type, highly energized and having charcoal or coke as the base. Such compounds have a high shrinkage and lose their carburizing power after 10 to 15 hours at heat, when the energizing chemicals are exhausted. A compound of this type will give a heavy case in a comparatively short time, which of course is desirable from a dollars and cents standpoint, but on account of the almost inevitable variation in furnace temperature during the heating period, there will also be a very distinct tendency toward unevenness in carbon content and depth of case between the work in different parts of a single pot and the work contained in different pots. This may be all right for certain classes of work, but is distinctly not satisfactory when making roller-bearing parts where absolute control and evenness in the case is essential. With the slow carburizer and long time at heat, which features Timken practice, it will make no discernible difference if one pot should reach carburizing temperature slightly ahead of other pots in the furnace. The firing is, moreover, so regulated that there is a minimum danger in this respect.

The work is packed with bone meal into pots made of Nichrome, which alloy has been found to give very satisfactory service. This packing is done by hand by operators sitting in front of the pots with a pan of work on one side and a can of meal on the other. After spreading about 1 in. of meal in the bottom, a row of rings is laid in; this is barely covered with meal and smoothed down and patted in place with a little tamper such as is shown in Fig. 3. The usual practice is to pack the cones inside the cups of the same bearing and reasonable care is taken that the different parts do not touch one another. Two inches of carburizer is always provided at the top of the pot. Rollers are simply scooped into the pots in layers, and contrary to the usual experience in carburizing—that soft spots will be obtained in hardening if the parts touch one another—it has been found that no trouble is experienced in this respect. The reason for this doubtless is that with the long time at heat required by the Timken practice, the carbon has an opportunity to equalize by diffusion, which is not possible when, as in most places, a total time of only 4 to 10 hours is allowed in the furnaces.

ALLOY POTS

Various shapes and types of pots have been used, but best results are obtained with round pots, such as shown in Fig. 4. The pots are considerably larger than the pots used in most other plants, and on account of the size and the slowness of heat penetration with bone meal, the pots are made with a 4-in. chimney in the middle. To facilitate the handling and to allow for heat penetration also from the bottom, the pots are made with stout legs 2½ in. high, and lately legs have been placed also toward the middle of the pots to prevent the bottom sagging. Covers are made with flanges fitting around the chimney and against the wall of the pot. After the pot is filled the cover is rammed down and the fit is close enough to eliminate the use of luting clay. This is one great advantage over steel pots, as when clay is used it is difficult to prevent dirt from getting mixed into the meal and afterward cause soft spots in the hardening operation. Eliminating the clay sealing also facilitates handling the pots and taking out the control samples. It can be mentioned that on the scale on which carburizing is carried out in the Timken plant a saving of two to three men's labor is obtained simply by eliminating this luting operation. Covers are made with flanges on both sides and are used indiscriminately with one or the other side up—this in order to avoid sagging and cracking around the flanges. We have tried other types of pots, of square or rectangular shape,

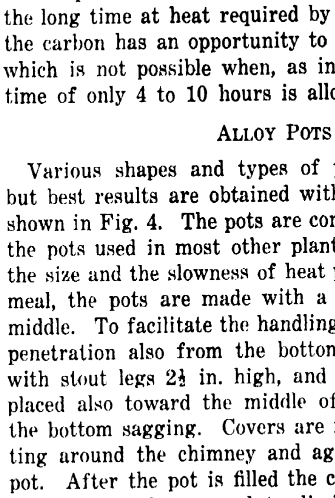

FIG. 4—NICHROME POT

but the sides of these containers warped and cracked badly, and with the exception of a few old pots, the use of this type has been discontinued. Steel pots have also been employed to some extent, but are no longer used. Besides having a short life they scale and warp badly, are very heavy, and heat penetrates slowly through the scaled surfaces. In spite of the lower price per pound, steel pots are in the long run more expensive per heat-hour, and require much more work for handling and sealing. Pots of other heat-resisting alloys than Nichrome have been tried, some with fairly good results, and some with results not

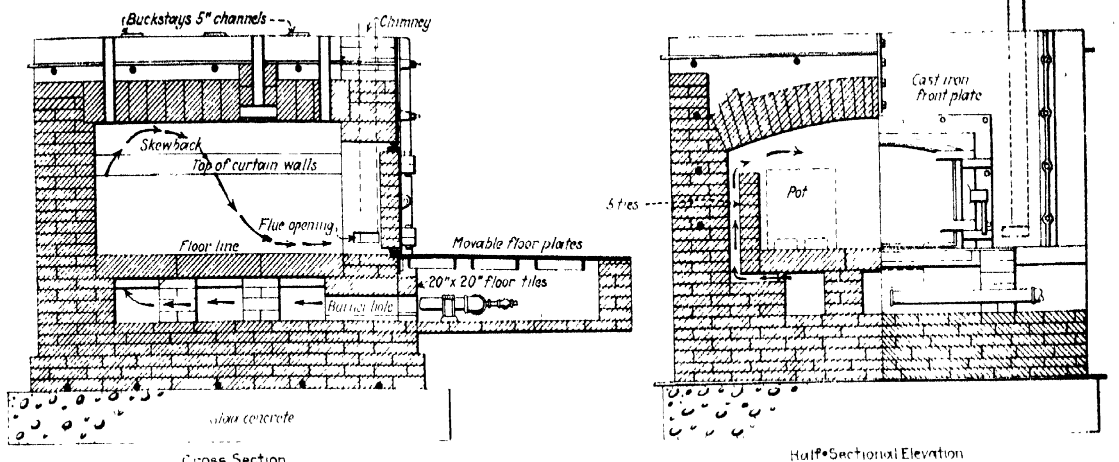

FIG. 5—CARBURIZING FURNACE UNIT

so good. As far as resistance to heat is concerned, several have been satisfactory, the trouble usually being that the legs break off due to a brittle metal and the rather rough handling to which the pots are exposed.

All Nichrome pots are guaranteed for a certain minimum time in service, and in order to keep track of the different pots large identification numbers are cast on the outside of each pot. The furnace hours for each pot are recorded on special sheets, and the time is computed for each pot four times annually. With about 1,500 pots in service, this is quite a job, but it is necessary and in fact pays for itself. The majority of the pots give much more than the guaranteed life, some still being in good condition after more than 10,000 heat-hours, but others, especially those of square design, have not given such good account of themselves. Most of the failures have been due to weak legs, which, however, has now been entirely overcome by an increase in section. Occasionally a pot must be discarded because it cracked around the chimney or developed holes in the sides or in the bottom, these latter defects probably being caused by segregations. However, the latter types of failures have been scarce. In this connection it might be mentioned that Timken practice presents exceptionally favorable conditions for alloy pots, what with slow heating, long heats and a compound containing no energizing chemicals. Rapid and repeated heating or cooling is naturally very damaging to pots of any kind, and it is well known that energized compounds containing cyanogen salts (and to a certain extent sodium carbonate) have a deteriorating influence on nickel-chromium alloys.

Carburizing Furnaces

The packed containers are heated in special furnaces to a temperature of 1,680 to 1,700 deg. F. and kept at this temperature for various lengths of time, depending on the depth of case required. Seventy furnaces, each with a floor space of 5x5 ft., are available, grouped in three blocks and built side by side and back to back, strongly bound together with rods and buckstays (Fig. 5). Such a construction obviously conserves the heat very well, since the individual furnaces radiate heat only through top, bottom and front. The door is a large iron casting hinged on one side and lined inside with a cement-Silocel mixture. It swings open quite easily, but can be held tightly shut by wedging against a cross-bar. When heat is on, all edges are carefully luted with clay. The furnaces are of the underfired type, with a hearth of flat tiles. These are supported by firebrick walls running from front to back, forming a labyrinth through which the flame and hot gases must pass, backward and forward, until they find their way out up the slots formed by the side walls and the vertical tiling set at the side of the hearth. In the furnace chamber the moving gases strike the arched roof, are deflected back down upon the pots, work their way forward and pass through low openings near the door into

FIG. 6—REMOVING A HOT BOX

small exhaust chimneys built in both door jambs. With this method of heating and the construction of twenty to thirty furnaces in one block of brickwork, the temperature distribution in a furnace is extremely uniform, and it is very rare to note any material difference in the quality and depth of case in the different pots that constitute one furnace load. If such a difference is observed, it indicates that the furnace is burned out and should be rebricked.

Heat is supplied by one centrally located burner in front of each furnace. This principle of using one single burner for each furnace is, by the way, a distinct feature in all furnaces used in the Timken plant and it is obvious that firing is thus simplified to a large degree. *Natural gas is used when this is available*—i.e., during summer—and oil during the remainder of the year. Gas firing allows slightly better control and with the burners with dirt and coke. Burners are so made that they can be used for either gas or oil and connected up in such a way that a change from one fuel to another can be made on a minute's notice. The consumption of oil per furnace when up to heat is about 3 gal. per hour and somewhat higher during the heating period.

The loaded carburizing pots are charged into the furnaces by means of special trucks, such as shown by the foreground of Fig. 6. It is usually possible to arrange the schedule so that one full furnace load of nine pots, containing work that requires the same depth of case, can be charged in the same furnace. If this is not possible, the pots with work where a thinner case is desired are charged in front and later withdrawn ahead of the rest of the pots. In moving the pots forked tongs on the front of the truck are slipped under the bottom

FIG. 7—BATTERY OF LEEDS & NORTHRUP RECORDERS

prevailing prices is cheaper, but is harder on the furnaces. A furnace on gas has to be rebuilt about twice as often as when using oil as fuel. In order to obtain proper results it is necessary that a high grade of light oil be employed, and every carload is therefore submitted to laboratory tests for residual carbon, fluidity and to other routine tests before it is pumped into the storage tanks. Oil is supplied to the furnaces through a circulating oil system—i.e., the oil pumps are so dimensioned that they will supply an amount of oil many times in excess of the consumption and the excess oil is carried back to the storage tanks. Pressure is kept constant by pressure regulators on the feed and return lines, the former adjusted to 60 to 70 lb. immediately beyond the oil pumps, and the latter to give 35 to 40 lb. immediately ahead of the discharge to the storage tanks. This system is much to be preferred to a dead-end system, as it facilitates an even adjustment of the oil pressure and has much less tendency to clog up of the pot, between the short legs, and the leverage provided by a long handle is great enough so that the operator can balance the 300 to 400 lb. weight of the loaded pots and move them around rapidly and with great ease. He can also reach into the far corner of the furnace without coming too close to the hot door. All the furnaces are built with their floors level with the aisles, which in turn are paved with cast-iron plates, and the charging or discharging of a furnace can, by means of these trucks, be done in from 5 to 10 minutes. When a charge has been drawn the hot furnaces are reloaded and sealed as quickly as possible. Some of the floor plates in front of the furnace are removed, opening the pipe trench and exposing the burner and its port hole. Control valves for fuel and air are located at handy places in front of the door jambs. Firing at the start is relatively brisk, so that the cold pots may not draw heat from the surrounding brickwork too rapidly and disturb the temperature in adjoining ovens. It is

desired that all charges be brought to heat in 10 hours, a time sufficient to insure that no great difference in temperature exists between the different pots and from center to outside of the individual pots. As previously noted, further assurance regarding the uniformity of the case is obtained by the use of a slow carburizer, and even if the work in one pot should be at effective carburizing temperature 30 minutes longer than the work in another pot, the variation in case cannot be measured.

It might be thought that fuel economy would demand quicker heats, but the construction of the furnaces is such that only 3 gal. of oil, costing about 6 cents a gallon, is required per hour for one furnace, and the extra cost for several hours' heat is compensated by the saving in labor from packing and handling the work in large pots and the greater regularity of the results obtained. It is quite true that more equipment and furnaces are necessary, but careful calculations in regard to the saving of labor cost show that the actual cost of carburizing by the Timken practice is not higher than though a faster carburizing process were used. Even if the cost should be higher, it would be many times repaid by the high and uniform quality of the casehardened work, which is absolutely essential for the parts in a bearing. Moreover, a few rejections at this stage in the operation would amount to more than the cost of the entire carburizing operation. It is not the intention to criticise in any way the practice for carburizing used at other plants, as it is realized that for many purposes faster methods and compounds can be used, but for the very accurate work necessary in making roller bearing parts, only a method such as outlined above will give satisfactory results.

Platinum Couples Used

Temperature in each furnace is measured by platinum thermocouples used in conjunction with indicating and recording potentiometers. The thermocouple is protected by a short quartz tube, extending through the arch at about the middle, and projecting down 3 in. into the furnace. The other (cold) end is surrounded by water jackets and with open discharge overflowing in front of the furnaces so that it can be instantly seen whether all cooling jackets are working properly. Thermocouples are welded to extensions of copper wire that are connected in the usual way by a double-wire system to mercury selective switches in the furnaceman's office and extend to the main pyrometer room. (Some years ago the usual system with a common return line to all thermocouples was used, but it did not prove satisfactory.) In the furnaceman's office individual readings by a potentiometer indicator are made and recorded for each furnace at 30-minute intervals. This record guides the fireman, and he constantly refers to it and adjusts each burner valve accordingly. The main pyrometer room holds the recorders (one battery is shown in Fig. 7) so that heating curves can be obtained on every heat, if a furnace load for one reason or another should not give the desired results.

It has been said that this installation of platinum couples with water-cooled cold ends is unnecessarily expensive, but careful calculations have shown that in the long run, in spite of the high cost of installation, this system does not cost more than the usual installation of base-metal couples. Our pyrometers last indefinitely; one man has no trouble in taking care of about 150 couples, checking them for accuracy once a month. The cost of maintenance is therefore very low as compared with other systems. Moreover, in this line of work, there is only one thing that counts—accuracy—and a few spoiled heats due to defective couples would pay for a very large part of the installation.

After reaching temperature, the furnace is held within 10 deg. F. plus or minus for a length of time, varying from 4 to 50 hours, depending upon the required depth of case. The shorter time will produce a case $\frac{1}{64}$ to $\frac{1}{32}$ in. deep, while the latter will give $\frac{3}{32}$ to $\frac{7}{64}$ in. penetration. The depth of case that can be expected after various lengths of time at heat has been carefully determined by experiments. In addition test specimens are packed in each pot, strung on a loop of wire, one end of which is hooked over the edge of the pot. When the time is judged right, the furnace is opened long enough to withdraw one pot, the samples are quickly extracted without disturbing the contents materially, water quenched and broken with a sledge. Visual examination after dipping in 10 per cent nitric acid indicates to the inspectors whether the desired depth of case has been obtained. If not, the pot is replaced, the furnace sealed and firing recommenced. After an appropriate time, a second pot is withdrawn and test specimens again quenched, broken and examined.

When a furnace load is approved by the inspectors, the pots are removed from the furnace and trucked to a cooling alley, where they stand in open air, requiring about 6 hours to reach 150 deg. F. From each pot is taken a sample of the work, which is reheated to 1,420 to 1,440 deg. F. in a small furnace, quenched in water and broken. After etching the fracture in 10 per cent nitric acid the depth of case may easily be estimated by the dark ring produced. Each individual pot is thus tested and the release is indicated by insertion of rods with attached tags of various colors, showing the nature of the work in the pot and giving instructions for further handling.

When the pots are thus released they are trucked over to a metal screen, No. 4 mesh, set flush with the floor, and dumped upside down. The meal sifts through the screen like dry sand, drops into a hopper, and leaves behind the various carburized parts on the screen. They can then be shoveled into pans and barrels for transfer to the hardening room. Meal is taken from the underground hopper by a screw conveyor and belt elevator to a closed storage bin. All these housings are connected to a suction exhaust and cyclone collector system, which is quite effective in keeping any dust from flying in the air. From the storage bin it is passed through a pug mill, fed automatically with three parts old and one part new meal. This drops into large containers, and these cans of carburizer are returned to the packing floor.

Hardening the Carburized Work

Hardening practice for cups and cones is different from that for rollers, and will therefore be dealt with separately.

Cups and cones are heated in specially designed rotary hearth furnaces, the general arrangement of which is shown in Fig. 8. It is 7 ft. in diameter, built like a turret with stationary side walls and roof, bound together with sheet steel. The moving hearth is annular and is covered with close-fitting segments of Thermalloy, a heat-resisting metal, resting on firebrick, which in turn is supported by a steel ring.

This flat ring rests on rollers, and has an annular rack attached to its lower surface, meshing with a bevel pinion, motor driven through a reducing gear and double speed changer. The speed of rotation can, through this arrangement and a system of double cones, be easily changed through a wide range, and the time for one revolution is so regulated that the parts will reach proper hardening temperature immediately ahead of the discharge door. For small work this time is 20 to 30 minutes and is increased to more than 1 hour for cups and cones of very large sections. The furnaces are heated by a single burner, centrally located, on top of the furnace.

The axis of the furnace—its "core," so to speak—forms a short combustion chamber from which the combustion gases, through slots, pass out radially into a second combustion chamber formed by the roof of the furnace and a false arch set about 5 in. lower. This lower arch has a series of fifteen long slots 3 in. wide equally spaced around the false arch except above the doors. The hot gases travel through the working chambers as indicated by arrows in Fig. 8, and escape through the front doors of the furnace. Of these there are two, the one to the left for charging and the other for removing heated rings after they have traveled around the furnace. By tilting the burner slightly it is possible to divert most of the hot gases to the side where the cold work enters the furnace, and this tends to equalize the temperature above the hearth.

A pyrometer is inserted through the roof immediately ahead of the discharge door. Couples are made of platinum, as in the carburizing department, and are protected by short quartz tubes. The cold end temperature is kept constant by a cold water jacket on top of each furnace. Couples are connected through copper wires leading to a selective mercury switch with an indicating potentiometer and in addition to this the temperature of the furnace is checked on recording instruments in the departmental office. One fireman looks after the temperature control for twenty-one of these furnaces, and he is solely responsible for the heat. Fuel and air valves are located at the back of the furnaces where they can be easily reached from a handy walkway. Oil consumption per furnace is between 2 and 3 gal. per hour. Hardening temperature is 1,420 to 1,430 deg. F. for the small sizes of cups and cones, and up to 1,470 for parts of larger section.

The latest development in regard to temperature control is the installation of automatic temperature regulators which are able to keep the temperature within ±5 deg. F. These controllers, which have been developed at the Timken plant, are extremely simple and much cheaper than any of the various devices now on the market. The principle is to divide the original oil line to the burner into two feed lines, each with a needle valve. One of these valves is adjusted so that if the oil was flowing permanently through this line the furnace temperature would be considerably above that desired, and the other valve adjusted so as to give a temperature somewhat below that desired. Oil is caused to flow alternately through one or the other of these valves by means of a small tapered valve with two orifices, from which pipes lead to the two needle valves. This valve is mounted on a shaft and can be brought to revolve about 90 deg. by means of arms with attached pins acting through two solenoids. Holes in the tapered valve are so arranged that when one is open the other one is closed, and vice versa.

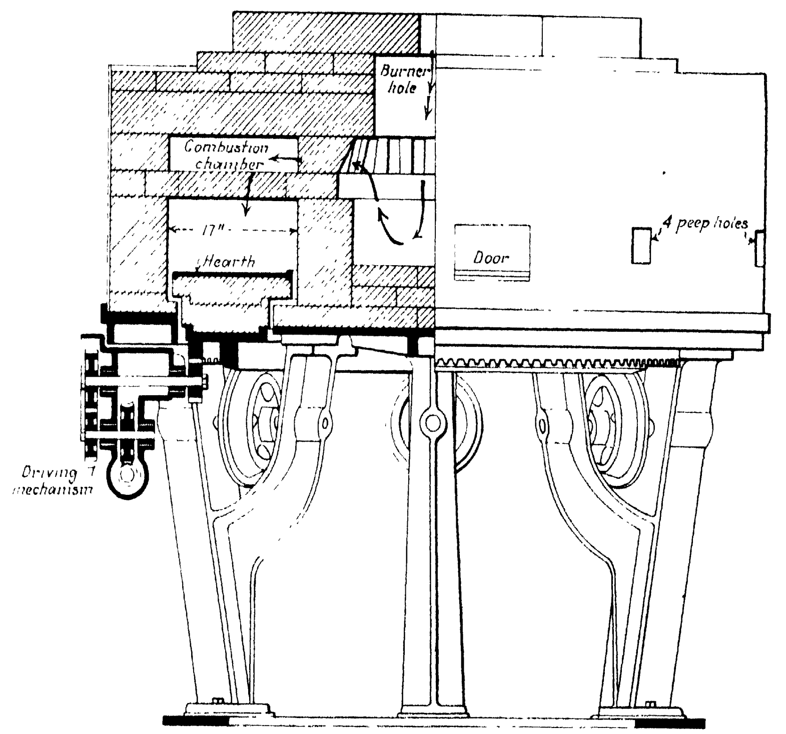

FIG. 8—SECTIONAL ELEVATION OF ROTARY HEARTH FURNACE

This apparatus works in conjunction with a Leeds & Northrup recording and controlling potentiometer and when the temperature becomes, say, 5 deg. higher than desired, a relay is closed, sending a current through one of the solenoids and causing an electromagnetic force to pull the pin in the core of the solenoid downward and through the arm attached to the shaft. The tapered oil valve is simultaneously caused to turn about 90 deg., thus shutting off the oil to the needle valve regulated for the higher temperature and opening the hole leading to the needle valve regulated to give the lower temperature. The action of the instrument when the temperature becomes too low is just the reverse. Thus the oil is caused to flow alternately through one or the other of the needle valves. The controller is so set that this change is effected as soon as the temperature on the thermocouple differs more than 5 deg. F. from that desired.

If only one furnace is controlled from each recording instrument the usual standard Leeds & Northrup in-

strument with signal lights can be used unaltered (or with a slight change in the circuit breakers to prevent arcing), with the wires to the red and blue lights reconnected to the two solenoids respectively. In order to reduce the cost of the instruments, however, it has been found desirable to connect more than one furnace to each recorder, and it is possible to run up to five furnaces from each controlling instrument. This necessitates rather elaborate switches and a very close setting of the oil valves. It has therefore been finally decided to control two furnaces from each instrument, which has proved very satisfactory, and it is now planned to extend the use of these automatic controllers all through the heat-treating department.

Quenching cups and cones is done in specially designed hardening machines, one placed in front of each furnace. Figs. 9 and 10 show these in outline and perspective. The main advantages of these machines are that they closely control the size of the hardened work. Quenching is also effected by means of a strong water spray instead of by mere immersion. A far more effective quench is therefore given than by the old methods and will give a more uniformly hard product. This is especially important for roller bearings, where soft spots would invariably mean failure in service.

The machine is equipped with two plungers that are moved up and down by the action of levers connected to an air cylinder as clearly shown in the drawing. Special fixtures are used for the hardening cups and cones in these machines. When a cup approaches the discharge door of the furnace, the operator lifts it out with a small hook, places it against the locating pins in the bowl, and turns the operating lever. This brings down the plunger, with the fixture attached to its lower end, into the cup at great speed. The spiral fluted fixture is larger than the hot cup and expands it a tiny bit. The bowl is depressed into the water basin, and at the same time water rushes up through the hole in the center of the bowl and out through the flutes in the fixture. Water from several jets also strikes the cups from the outside simultaneously and in this way the heated metal is rapidly chilled from both the inside and outside in such a way that there is a minimum chance for formation of gas bubbles or dead volumes in the quenching bath, and the ring is also rigidly held to shape during cooling. It has recently been found safer and more desirable to operate the water valves by a lever motion controlled from the upper toggles than by the valve pin arrangement shown in Fig. 9.

As the one side is operating in this manner, exactly the opposite sequence of events automatically takes place on the other side. The water jets close, the bowl and grill rise above the water surface, water is drained out of the bowl, the interior fixture rises clear of the hardened cup, which is hooked out and replaced by another hot one.

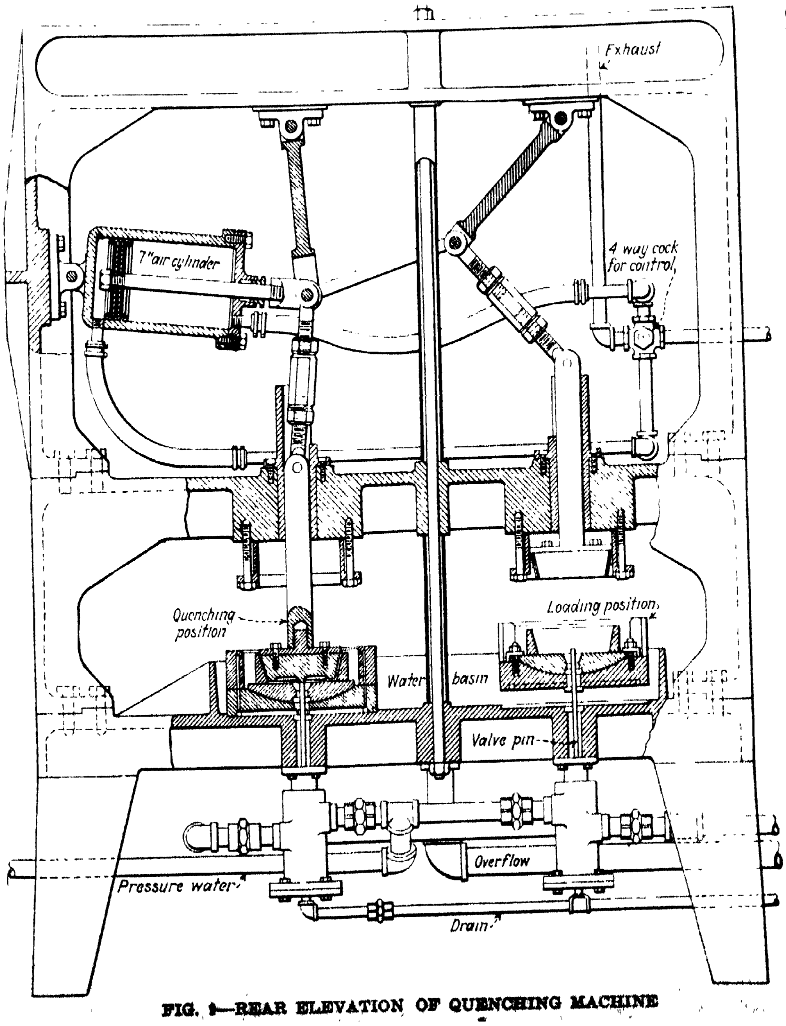

FIG. 9—REAR ELEVATION OF QUENCHING MACHINE

Cones are quenched in the same machine, but different fixtures are used. At times another type of machine is used, where the cones are simply submerged into water with a solid plunger inserted into the heated cones. Most cones, however, are hardened in the same machines as are the cups. The fixture used is a cylindrical plunger drilled centrally and split into six fingers. The lower end of the central hole is ground to a taper which, on the downward stroke, hits a pin of slightly larger size but of the same taper. This forces the fingers out, and the fixture is expanded tightly against the cylindrical bore of the cones.

These quenching machines are extremely speedy and one skillful operator, if he does not have to feed the furnaces, can harden 500 pieces per hour. In order to see that everything is working properly, inspectors check the product for size from the various machines three to four times an hour. In addition to this, all raceways are afterward subjected to a 100 per cent file inspection for hardness. Cones are tested by trying to touch them with new files around the circumference. For cups, which must be hard on the in-

FIG. 10—PERSPECTIVE OF QUENCHING MACHINE

side, a special method has been devised that in all its simplicity works very efficiently. By breaking a file a sharp edge is formed, which is poked against the inside of the cups in such a way that the cups roll slowly forward. If there are any soft spots the sharp point of the file will dig into the metal; the cups refuse to roll and then slide forward. A few scleroscopes are also used, but these are better adapted for checking the hardness of ground and finished work. Our experience is that a better hardness inspection is obtained by a file in the hand of a reasonably good man than by any other method. The main reason for this is that defects in casehardened work are mostly in the form of soft spots. Testing with a scleroscope would require a large number of readings on each part to find one soft spot, while a file test will cover a large area of the surface at one time.

HARDENING ROLLERS

There now remains to be told how the rollers are heat-treated. As noted before, the rollers are the parts in the bearings subjected to the most severe service and every effort is made to give them a correspondingly high strength. They contain 1 per cent chromium, and the hardening temperature is thus raised to about 1,500 deg. F. As a matter of fact, each roller is given a double quench, the first in oil from a temperature slightly above 1,500 deg. F. and the second in water from a temperature slightly below 1,500 deg. F. The intention of this double quench is to refine the case as much as possible and at the same time to obtain a fine-grained center. Experience has shown that better results are obtained by this method than by the usually employed method of a double quench from 1,550 and 1,450 deg. F. respectively. Our practice not only refines the outside layers of the case, but the refinement is driven the full depth of case in the carburized rolls.

Seventeen furnaces with rotary retorts shown in Fig. 11 are provided for this work. The furnaces were originally bought from an outside concern, but have been completely re-designed. The rolls are heated while passing through a Nichrome retort about 2 ft. in diameter and about 7 ft. long. This retort turns on three pairs of power-driven steel rolls, one of them engaging a double-flanged track to prevent endwise creep. By a similar arrangement to that used on the hearth furnaces, the speed can be regulated to suit the size of the work, the time for passing through the furnace varying from 10 to 25 minutes.

Work is moved forward by an inside spiral rib, about 3 in. high. Feed is regulated by an adjustable scoop attached to the cold end of the retort and dipping into a hopper filled with the little rollers. When the rollers have passed the full length of the retort they fall out

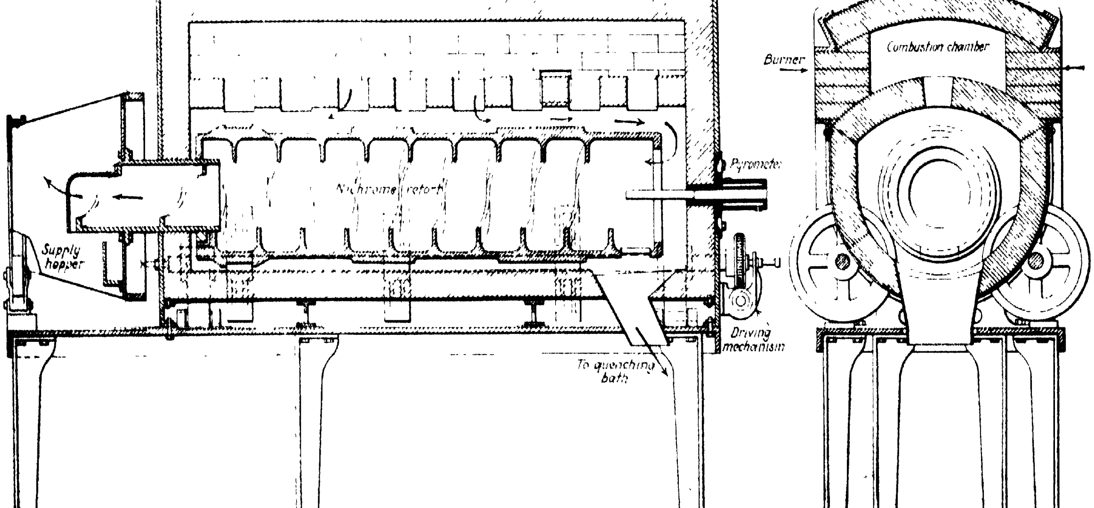

FIG. 11—ROTARY RETORT FOR HARDENING ROLLERS

through a slot in the wall and by means of a guiding chute into the quenching liquid.

The retort is contained in a brick chamber with double arches. The combustion chamber consists of the space between these arches; two oil burners project into this chamber in opposite directions, one near the front and the other near the back of the furnace. Hot gases are conducted through slots in the lower arch into the main furnace chamber, where they play around the retort and escape at the various joints. The burners are so adjusted that the heat gradient rises as the work progresses through the furnace, until proper hardening temperature is reached a little ahead of the discharge end.

As the rolls are discharged from the furnace, they are guided by a small chute, leading to the quenching bath immediately in front and below the furnace. Oil is used for the first quench and water for the second. The oil used is Houghton's No. 2 quenching oil, pumped from a large supply tank holding about 80,000 gal. As this tank is located at a considerable distance from the hardening room, radiation from the long pipe lines makes a special cooling plant superfluous. The oil for the first quench, as well as the water for the second, enters the cooling bath through several jets, set in various directions and so arranged that an effective and reliable quench of the rolls is obtained.

After having passed the quenching bath the rolls land on the inside of a partly submerged cylinder made of wire screen. Interior vanes are so arranged that as the cylinder slowly rotates the quenched rolls are elevated out of the bath and discharged over the edge of the tank into draining boxes set alongside.

Rolls are checked for hardness by file test and for fracture by splitting sample rolls at regular intervals in a small hydraulic press. In this way a very close control of the hardening of the rolls is maintained. After several cleaning operations done in rotary drums holding various substances, the rolls are ready for grinding and leave the hardening department.

In conclusion it can be said that no effort or cost has been spared in the development of the Timken heat-treating departments. Practically all of the equipment has been specially designed and a large number of patents have been granted on the various machinery that is used. The Timken company thus owns patents covering the rotary hearth furnaces, the quenching machines, the special fixtures used for hardening cups and cones, the temperature controllers, the roll-hardening furnaces and the quenching apparatus for the rolls, to mention only some of the more important. The high quality of the Timken bearings depends on these departments as much as on any other branch in the plant and they are equipped and conducted accordingly.

Composition of Beet Sugar Press Cake

The dry material of the filter press cake produced in the process of manufacturing beet sugar consists largely of calcium carbonate, according to the findings of the United States Department of Agriculture, and undoubtedly affords a satisfactory material for liming soils. It also contains comparatively small quantities of nitrogen, phosphoric acid, potash and organic material.

The results of the analysis of a number of representative samples of filter press cake are set forth in Department Circular 257, "Composition of Filter Press (Lime) Cake," by Sidney F. Sherwood, chemist in the Bureau of Plant Industry.

Coatings That Prevent End Checks in Wood

Wood dries more rapidly from the end grain than from the side grain, and is apt to check and split during seasoning unless end drying is retarded by some means. For this reason it is advisable to use a water-resistant end coating on wood during air seasoning or kiln drying, especially on woods which are difficult to dry and on short kiln samples.

Two Classes of Coatings

The coatings ordinarily used can be divided into two classes. The first are liquid at ordinary temperatures and can be applied cold. The second are solid at ordinary temperatures and must be applied hot. Cold coatings have the advantage that they may be used as easily on logs and lumber as on kiln samples and dimension stock; hot coatings, because of the method of application (end dipping), are not easy to use on large stock.

Either the cold or the hot coatings can be used effectively for drying temperatures up to 140 deg. F. Temperatures much above this cause blistering in the cold coatings, but make the hot coatings plastic enough to form new surfaces as fast as the old ones break. For this reason the hot coatings are apt to be more effective than the cold coatings for temperatures from 140 up to 170 deg. F., where they liquefy to such an extent that they run off. No coating has been found which is entirely satisfactory for temperatures above 170 deg. F. Cold coatings are perhaps somewhat better than hot coatings for temperatures above 170 deg. F. and for use on kiln samples when the temperatures are high enough to cause the loss of part of a hot coating.

Effectiveness of Cold Coatings

Cold coatings to be effective should have about the consistency of heavy sirup. The amount of filler required ranges from two to four parts by weight to one of the vehicle. Cold coatings used at the Forest Products Laboratory, Madison, Wis., have been found effective about in the following order, the most effective being placed first:

Hardened gloss oil and air-slaked lime (oil evaporated to consistency of thin sirup before adding the lime)	Very cheap
Chinawood oil and barytes	Cheap
Linseed oil and white lead (very heavy)	Moderate cost
Linseed oil and red lead (very heavy)	Moderate cost
High grade spar varnish and barytes	Expensive

Effectiveness of Hot Dips

The hot dips were effective in the following order:

213 deg. coal-tar pitch	Cheap
254 deg. coal-tar pitch	Cheap
Rosin and lampblack —(100 parts of rosin to 7 parts of lampblack)	Moderate cost

Some asphalts are highly moisture-resistant, but they are difficult to apply because of the high temperatures required to make them plastic.

Paraffine has proved very satisfactory as an end coating for stock during air seasoning, but cannot be used in the kiln because of its low melting point. Excessive shrinkage of the wood and rough handling often cause the end coatings to chip or shear off, and a fresh application of the coating must be made. To reduce end-drying sufficiently there must be a thick coating over the entire end surface. When hot dips are used, the wood should be dipped half an inch into the liquid.

This work has been carried out by the Forest Products Laboratory at Madison, Wis.

Licensing Laws for Engineers

A Survey of Licensing Conditions as Affecting Professional Engineers in Various States

THE situation regarding license laws for engineers is one that deserves the serious attention of chemical engineers everywhere. Already the movement has resulted in the passage in twenty-five states of laws which affect engineers in some way. In most of these states anyone engaged in work that is defined as "professional engineering" is required to obtain a license The New York State definition of "professional engineering" is the usual definition employed, and we quote:

Sect. 39-*n*. *Professional Engineering* A person practices professional engineering within the meaning and intent of this article, except as hereinafter stated, who holds himself out as able to do, or, who does, the work that an engineer does in the planning, designing, constructing, inspecting and supervising of engineering work, or appliances involved in public or private projects, or in making investigations for proposed engineering projects.

The New York law contains the following exemptions, usual but not contained in all state laws:

Nothing herein shall apply to a corporation, partnership or joint-stock association, provided the person or persons carrying on the actual practice of engineering on behalf of such corporations, partnerships or joint-stock associations shall be licensed engineers, and nothing in this article shall be construed to apply to the preparation or execution of designs, drawings, plans or specifications for the construction or installation of machinery or apparatus constructed or installed by the corporation, partnership or joint-stock association preparing such designs, drawings, plans or specifications if the supervision of the preparation of any such designs, drawings, plans or specifications, construction or installation shall be under the general direction of a licensed engineer.

QUALIFICATIONS FOR LICENSE

The qualifications for license are of particular interest to prospective applicants. Again the New York State law gives the average qualifications, and we quote an excerpt from this law which contains information on requirements and issuance of certificates and seals which will serve to illustrate to the reader what the majority of such laws cover:

EXTRACT FROM LAWS OF NEW YORK STATE

Chapter 775 as amended by Laws of 1921
Taking effect May 5, 1923

Sect. 39-*e* *Applications for and Issuance of Certificates.* The Regents, on application therefor, on prescribed forms and the payment of a fee of $25, except in cases where the applicant applies for license to practice professional engineering and land surveying, when the fee shall be $35; and except as hereinafter provided, shall on the recommendation of the board issue a certificate of license:

1. To any person who submits evidence satisfactory to the board that he or she is fully qualified to practice professional engineering or land surveying.

Provided, however, that no person shall be eligible for license as a professional engineer who is under 21 years of age, who is not of good character and repute and who has not been actively engaged for 4 or more years in the practice of professional engineering of a character satisfactory to the board.

Provided, however, that no person shall be eligible for license as a land surveyor who is under 21 years of age, who is not a citizen of the United States or who has not made declaration of his or her intention to become a citizen of the United States, who does not speak and write the English language, who is not of good character and repute and who has not been actively engaged for 3 or more years in the practice of land surveying of a character satisfactory to the board.

However, each 2 years of study, satisfactorily completed, of engineering in a school of engineering of standing satisfactory to the Regents shall be considered as equivalent to 1 year of such active practice

Unless disqualifying evidence be before the board, the following facts established in the application shall be regarded as prima facie "evidence, satisfactory to the board," that the applicant is fully qualified to practice professional engineering or land surveying.

(*a*) Six or more years of active engagement in professional engineering work, one of which shall have been in responsible charge of work, or in the case of applicants for license as a land surveyor, 4 or more years of active engagement in land surveying work of a character satisfactory to the board.

(*b*) Graduation, after a course of not less than 4 years in engineering, from a school or college approved by the Regents as of satisfactory standing, and an additional 4 years of active engagement in professional engineering, 1 of which shall have been in responsible charge of work, or 2 years of active engagement in professional land surveying of a character satisfactory to the board.

Applicants for license, in cases where the evidence originally presented in the application does not appear to the board conclusive or warranting the issuance of a certificate, may present further evidence, which may include the results of a required examination, for the consideration of the board.

In determining the qualifications of applicants for license as professional engineers or land surveyors a majority vote of the members of the board shall be required to pass the candidate.

In case the board denies the issuance of a certificate to an applicant, the license fee deposited shall be returned by the Regents to the applicant.

2. To any person who holds an unexpired certificate of license issued to him or her by a legally constituted board of examiners in the District of Columbia or in any state or territory of the United States in which the requirements for the license or registration of professional engineers or land surveyors are of a standard not lower than those prescribed in this state, provided that an agreement of reciprocity in the matter of indorsement of such certificates of license shall have been entered into between the Regents of the University of the State of New York, the board of examiners of this state and the like duly constituted authorities in the District of Columbia or in any other state or territory of the United States.

Sect. 39-*f*. *Certificates.* The result of every examination or other evidence of qualifications, as provided by this article, shall be reported to the Board of Regents by the board of license, and a record of the same shall be kept by the Board of Regents; and the Board of Regents shall,

SURVEY OF STATES HAVING LICENSE LAWS

Name of State	Affects Ch. Eng'r.	Where to Apply for Complete Information
Alabama	Yes	Judge of Probate in each county
Arizona	Yes	State Board of Registration of Architects and Professional Engineers, Phoenix
California	No	Surveyor-General, State Capitol, Sacramento
Colorado	Yes	State Board of Examiners for Engineers and Land Surveyors, Denver
Florida	Yes	State Board of Engineering Examiners, G K. Armes, Sec, Tallahassee
Idaho	Yes	Department of Law Enforcement, Paul Davis, Boise
Illinois	No	Department of Registration and Education, Springfield
Indiana	Yes	State Board of Registration for Professional Engineers, DeW D Moore, Indianapolis
Iowa	Yes	State Board of Engineering Examiners, K. C. Kastberg, Sec, Des Moines
Louisiana	No	State Board of Engineering Examiners, Baton Rouge
Michigan	Yes	State Board of Examiners of Engineers, George Jerome, Sec, Detroit
Minnesota	Yes	State Board of Registration of Architects, Engineers and Land Surveyors, St Paul
Nevada	Yes	State Board of Registered Professional Engineers, Carson City
New Jersey	Yes	State Board of Professional Engineers and Land Surveyors, Trenton
New Mexico	No	Board of Examining Surveyors, Santa Fe
New York	Yes	State Board of Licensing for Professional Engineers, Albany
North Carolina	Yes	State Board of Registration for Engineers and Land Surveyors, Raleigh
Oregon	Yes	State Board of Engineering Examiners, A. B Carter, Sec, Portland
Pennsylvania	Yes	State Board of Registration of Professional Engineers and Land Surveyors, Harrisburg
South Dakota	No	State Engineer, Pierre
Tennessee	Yes	State Board of Examiners for Architects and Engineers Nashville
Texas	No	Board of Examiners of Land Surveyors, Austin
Virginia	Yes	Board for Examination and Certification of Professional Engineers, Richmond
W Virginia	Yes	State Board of Registration of Engineers, George F Taylor, Sec, West Union
Wyoming	Yes	Board of Examining Engineers, Fremont Morrison, Sec Cheyenne

unless deemed otherwise advisable, issue a certificate of license to every person certified by the board of license as having passed such examination or as being otherwise qualified to be entitled to receive the same.

Sec. 39-i. *Significance of Certificate—Seals.* The issuance of a certificate of license by the Regents shall be evidence that the person named therein is entitled to all the rights and privileges of a licensed professional engineer or land surveyor, while the said certificate remains unrevoked or unexpired.

Each licensee hereunder may upon being licensed obtain a seal of the design authorized by the board, bearing the licensee's name and the legend "licensed professional engineer or licensed land surveyor." Plans, specifications, plats and reports issued by a licensee may be stamped with said seal during the life of licensee's certificate, but it shall be unlawful for anyone to stamp or seal any documents with said seal after the certificate of the licensee named thereon has expired or has been revoked unless said certificate has been renewed or reissued.

Extract From Rules of the Board of Licensing

Responsible charge of work, as referred to in the act, shall be understood to mean the control and direction of the investigation, design and construction of work requiring initiative, skill and independent judgment in meeting unforeseen conditions. The board, in passing on this requirement, will carefully weigh the evidence of experience submitted by the applicant.

The term "principal" as used in the act will be understood to mean an engineer in charge of work who is directly responsible to his client, employer or superior officer for results in connection therewith, even though he may have under his supervision and direction on such work assistants who have responsible charge of certain features thereof.

Conditions in Various States

While the conditions for licensing vary somewhat among states, most states have requirements equal to or less than those of New York. Those states having more severe requirements are Colorado, Illinois, Indiana, Pennsylvania, Tennessee and West Virginia.

In some states the provisions apply only to special classes of engineers and do not apply to chemical engineers. We give herewith, in table form, the states requiring license; those in which chemical engineers are affected; and the address to which to write for complete information.

Moisture-Resistant Coatings for Wood

Shrinking and swelling and internal stresses causing warping and checking are brought about in wood by changes in the moisture content. Such changes are occurring continually when wood is exposed to changing atmospheric conditions, and the only way to prevent or retard them is to protect the wood from the air with some moisture-resistant finish or coating.

In order to determine the protection against moisture afforded by various coatings, a series of tests is being conducted by the U. S. Forest Service, at the Forest Products Laboratory, Madison, Wis. No coating or finish which is entirely moisture-proof has yet been discovered, but several have been found which are very effective.

Linseed oil, although it is probably recommended more frequently than most of the other materials for moisture-proofing wood, was found in the absorption tests to be quite ineffective. Five coats of hot oil followed by two coats of floor wax failed to give any great protection.

Oil paints form a film over wood which is very durable even in exterior locations. Laboratory tests show, however, that such a film, although it may be continuous, does not prevent moisture changes in wood. Graphite paints and spar varnish are about as effective as the ordinary oil paints with the heavier pigments.

RELATIVE EFFICIENCY OF WATER-RESISTANT COATINGS FOR WOOD

	Percentage Efficiency
Aluminum-leaf process—asphalt paint base	98
Three coats spar varnish coated with vaseline	98
Three coats of asphalt paint	96
Aluminum-leaf process—spar varnish base	95
Aluminum-leaf process—cellulose lacquer base	94
Aluminum-leaf process—oil paint base	93
Three coats of aluminum bronze (quick drying)	92
A heavy coating of paraffine	91
Three coats of rubbing varnish	89
Three coats of enamel	88
Three coats of orange shellac	87
Three coats of cellulose lacquer	73
Sheet pyralin 0.005 in. thick glued to wood	68
Three coats of graphite paint	61
Three coats of spar varnish	60
Three coats of whitelead oil	54
Five coats of linseed oil applied hot and two coats of wax	38
No coating	00

Cellulose lacquers rank somewhat higher than the foregoing in moisture resistance. Considerable improvements can probably be effected in them by the addition of solids. They have the advantages that they are fast drying and that the films they form over the wood are very elastic.

Rubbing varnishes afford considerably more protection against moisture than do spar or long oil varnishes. The larger amounts of gum solids present in rubbing varnish probably account for their greater moisture resistance.

Enamel coatings made by the addition of pigments, such as barytes, to ordinary varnish are about as effective as rubbing varnish.

A bronze coating composed of a cheap gloss oil and aluminum powder proved in tests to be superior in moisture resistance to any of the coatings mentioned above. This mixture is very fast drying; three coats can be applied in the course of half an hour.

The aluminum-leaf coating developed at the Forest Products Laboratory particularly for the protection of airplane propellers is highly efficient in preventing moisture changes in wood. Such a coating can best be applied to large unbroken surfaces.

For temporary protection against moisture changes, vaseline smeared over varnish is one of the most moisture-resistant coatings yet tested.

The accompanying table gives the results of moisture absorption tests on panels coated with the different preparations. The percentages are based on average amounts of moisture absorbed per unit surface area by coated and uncoated panels subjected to a humidity of 95-100 per cent for 14 days.

Increase in British Exports of Tin

During the months of December and January the quantity of tin plates exported to the United States from Great Britain totaled more than the amount sent in the whole of the preceding 36 months. From other parts of the world as well there has also been a noticeable revival in the demand for tin. As a result Britain's exports are now between 42,000 and 43,000 tons per month. As will be seen from the following statistics, Britain's tinplate industry centering in South Wales has practically regained its pre-war position as an exporter.

Year	Gross Tons	Value, f.o.b.
1913	494,497	£7,214,938
1920	353,058	18,954,053
1921	226,440	9,077,[illegible]
1922	448,907	9,695,936

How Do You Operate A Column Still?

By F. H. Rhodes
Professor of Industrial Chemistry, Cornell University

THE column stills commonly used for the separation and rectification of liquids by fractional distillation consist of the following essential parts:

1. The still body, or "kettle."
2. The fractionating column, in which the original vapor from the still is caused to pass upward countercurrent to and in intimate contact with a downflowing stream of "reflux" introduced at the top of the column.
3. The partial condenser, or "dephlegmator," in which a portion of the vapor from the top of the column is condensed and returned to the top of the column as "reflux," while the remainder of the vapor is allowed to pass forward to the final condenser.
4. The final condenser, in which the vapor is condensed completely to "distillate" and the distillate is cooled so that it may be sent to the receivers

Of course the partial condenser method is the one that is generally practiced. This has certain distinct disadvantages as compared with the single condenser method of operating a column still, among which are the greater ease of control and the greater constancy of the reflux-distillate ratio under varying conditions of operation. This article tells why the single condenser method is better.

The general arrangement of such a still designed for operation by the "partial condenser method" is shown diagrammatically by the accompanying Fig. 1.

The primary purpose of the partial condenser is to provide the reflux to the column so that the column may continue to act as a fractionating device. The same result may be secured by omitting the partial condenser entirely and providing the necessary reflux by condensing all of the vapor in a single condenser and properly dividing this total condensate into reflux and distillate by means of valves or other suitable device. The general arrangement of such a still arranged for operation by the "single condenser method" is shown diagrammatically by the accompanying Fig. 2.

This method is not new; it has been described repeatedly in the literature and has been used commercially to a limited extent. In most industrial distillation operations, however, the feasibility of the single condenser method has not been realized and its advantages have not been appreciated, so that at present most fractional distillation operations are carried out in stills provided with a partial condenser and operated by the partial condenser method.

This present article was written for the purpose of calling attention to some of the advantages, from a practical operating standpoint, of the single condenser method of still operation. With any given column, operating on an initial vapor of any given composition, there is an optimum ratio between the portion of the total condensate returned to the column as reflux and the portion taken off as distillate. With less than this optimum reflux ratio the fractionation will be insufficient to give a distillate of the attainable and desired purity; with a reflux ratio greater than the optimum ratio a very slight increase in the purity of the distillate will be secured at the expense of a very considerable increase in the time and the amount of heat required to produce a given quantity of distillate. It is obvious, therefore, that the maximum efficiency and economy of operation can be secured only by maintaining, at each stage of the distillation, a certain definite ratio between the reflux and the distillate; and that variation from this optimum ratio will result either in unduly impure distillate or in unnecessary cost of operation.

It is difficult, with a partial condenser, to maintain a constant ratio between reflux and distillate. The usual type of partial condenser consists of a set of vertical tubes through which the vapor is passed and around which the water or other cooling medium is circulated, although in some cases partial condensers are used which consist of a set of horizontal tubes through which the water is circulated and around which the vapor is passed. In either case, a change in the temperature or in the rate of flow of the cooling liquid produces a change in the amount of vapor condensed in the partial condenser and thus causes a variation in the reflux ratio. Moreover, when the partial condenser is carefully regulated to give a uniform *amount* of reflux, the *ratio* of reflux to distillate may be changed by a variation of the rate of distillation of the charge within the still body. It is obvious, therefore, that in a still provided with a partial condenser maximum efficiency and economy can be secured only by maintaining very close control over the operation of the partial condenser.

In a still arranged for operation by the single condenser method it is possible to install, below the condenser, a dividing device which will automatically separate the condensate into reflux and distillate and which can be set to maintain any desired ratio between reflux and distillate. In this way the ratio of reflux to distillate can be kept constantly at the optimum value and the still can be operated constantly at maximum efficiency, irrespective of any probable fluctuation in the temperature or the rate of flow of the cooling water or in the rate of distillation. Therefore the still can be operated more efficiently and more economically and with less supervision than can a still operated by the partial condenser method.

Another advantage of the single condenser method of operation is the ease with which the reflux ratio can be adjusted to meet changes in the composition of the vapor entering the fractionating column. In any dis-

continuous distillation process the vapor entering the bottom of the column becomes progressively poorer in the lighter component as the distillation proceeds, and in running any particular fraction it is necessary to increase the reflux ratio progressively to meet this change in vapor composition; in any discontinuous distillation process there may occur variations in the composition of the feed which necessitate a change in the reflux ratio. In a still operated by the partial condenser method this change in reflux ratio is effected by changing the rate of flow of the cooling water. The exact effect of any given change in the rate of flow of cooling water can be predicted only by experience and determined only by trial. Moreover, the full effect of a given change in the rate of flow of cooling water does not appear at once, but develops rather slowly. These facts render it necessary to control a partial condenser still largely by the method of "trial and error" and necessitate close attention and frequent regulation in order to obtain satisfactory results.

Moreover, the difficulties of control make it difficult to standardize the operation of the still and make it necessary to rely very largely upon the judgment of the still runner. In a still operated by the single condenser method, the dividing device can be calibrated and provided with a scale to indicate the ratio between reflux and distillate corresponding to any position of the divider. The exact effect of a given change in the position of the divider can be foretold very closely and the change in reflux ratio necessary to meet any change in the conditions within the still can be made easily and quickly. Moreover, the full effect of a change in the reflux ratio appears very soon after the change is made. For these reasons, a still operated by the single condenser method requires a minimum of attention, and the operation of such a still can be standardized so that it is not necessary to rely so much upon the judgment and experience of the still runner.

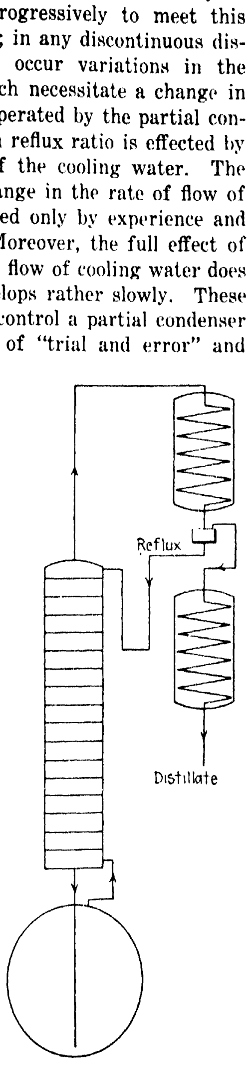

FIG 1—PARTIAL CONDENSER METHOD

A third advantage of the single condenser method is the fact that it can be applied successfully to the fractional distillation of high-boiling liquids, while with the partial condenser method the regulation of the reflux ratio (and therefore the proper control of the fractionation) becomes very difficult when working with substances which boil at temperatures considerably above the boiling point of water. In a partial condenser handling vapors which condense below, or only slightly above, 100 deg. C. the reflux may be regulated by varying the rate of flow of cooling water through the condenser. With vapors condensing at somewhat higher temperatures, the dephlegmator may be partly filled with water which is kept boiling by the heat absorbed from the vapor, and the amount of material condensed as reflux may be varied by varying the *height* of the boiling water surrounding the condenser tubes.

This method is not very satisfactory, because the exact regulation of the height of the boiling water in the condenser is rather difficult and because a slight change in the height of the water may produce a very large change in the amount of material condensed as reflux. With vapors which condense at temperatures considerably above the boiling point of water it is usually necessary to resort to the use of air-cooled partial condensers, which are very difficult to regulate, or to use partial condensers cooled by circulating oil, which present obvious operating difficulties. With the single condenser method of operation, high-boiling liquids can usually be handled in essentially the same manner as liquids which condense at relatively low temperatures—i.e., with a water-cooled condenser and a dividing box—and the reflux ratio can be controlled as accurately and as easily as when working with liquids which condense at temperatures below the boiling point of water.

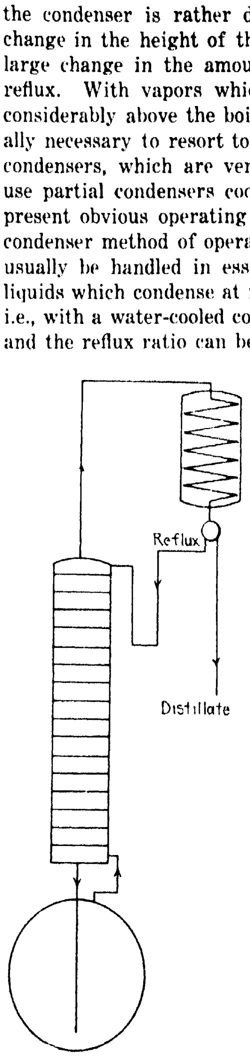

FIG. 2—SINGLE CONDENSER METHOD

For example, naphthalene may be distilled fractionally by the single condenser method about as easily as can benzene, whereas the fractional distillation of naphthalene in a still operated by the partial condenser method presents considerable difficulty. Of course, if the distillate has a melting point above the boiling point of water, it will be necessary to use an air-cooled condenser instead of a condenser cooled by water, but even this introduces no particular difficulty, since it is not necessary to *regulate* the amount of condensation in the air-cooled condenser, but only to insure that the amount of cooling surface is sufficient to condense all of the vapor. Thus it is evident that the single condenser method of distillation has a much wider range of application than has the partial condenser method.

Some Objections to the System

One objection to the single condenser method of operation that is sometimes raised is that it is not possible, by this method, to recover and utilize the heat contained in the vapor. In continuous stills operated by the partial condenser method the crude liquor going to the still is frequently used as the cooling medium in the partial condenser, so that the heat liberated by the condensation of the reflux is utilized to preheat the still charge. In a single condenser still exactly the same result may be secured by building the condenser in two sections in series, the upper section being cooled by the ingoing charge to the still and only the lower section being cooled by water, and the total condensate from the entire condenser being separated into reflux and distillate by means of the dividing device. In some

cases it is even possible to condense all of the vapor in a single condenser cooled by the ingoing charge and to pass only the condensed distillate through a water-cooled "cooler" placed below the dividing device; and in such cases the amount of heat recovered is actually greater than the amount usually recovered in stills operated by the partial condenser method. The use of such a two-stage condenser or of a condenser and cooler does not in any way interfere with or complicate the control of the reflux ratio. Therefore it is evident that the thermal efficiency of a still operated by the single condenser method is just as high as the thermal efficiency of a still operated by the partial condenser method and giving the same quality of distillate from the same still charge.

Another objection to the single condenser method of operation is that the reflux has exactly the same composition as the distillate, whereas the reflux obtained from a partial condenser is richer in the heavier components and poorer in the lighter component than is the distillate. In other words, by adopting the single condenser method we sacrifice the fractionating effect of the partial condenser. It is true that the partial condenser does act, to a certain extent, as a fractionating device, but it is also true that as a fractionating device the usual form of partial condenser is very inefficient. The contact between liquid and vapor is poor, there is considerable difference in temperature between vapor and condensate, and the condensate and vapor usually flow in parallel rather than in counter current through the condenser.

In running pure fractions the difference between the reflux and the distillate is usually so slight as to be undetectible; in running wide-boiling or intermediate fractions there may be considerable difference in composition. In practically every case, however, the increased fractionation and the greater purity of the product obtained by the use of a partial condenser could be secured in a still operating on the single condenser method by simply adding one more plate to the column. Furthermore, it is possible to use, in a single condenser installation, a condenser which is made up of two units in series, and so to arrange the dividing box that substantially all of the reflux is obtained from the first unit and substantially all of the distillate is obtained from the second unit. In this way the advantages of the single condenser method of operation can be secured without sacrificing the slight fractionation obtained by the use of a fractional condenser

SUMMARY

In summation, therefore, the single condenser method of operation offers the following advantages:

1. The ratio between the reflux and the distillate may be maintained constant at any desired value, irrespective of any fluctuation in the rate of flow or the temperature of the cooling water or of any variation in the rate of distillation.

2. The reflux ratio may be more easily regulated, thus permitting better control of the fractionation and making it possible better to standardize the operation of the still.

3. Fractional distillation may be applied to the separation and purification of high-boiling materials as well as to the rectification of liquids which boil at relatively low temperatures, and the close control of these high-temperature fractional distillations presents no particular difficulty.

The thermal efficiency of a fractional distillation process controlled by the single condenser method need be no lower than the thermal efficiency of a similar distillation process controlled by the partial condenser method—it may, in some cases, be higher.

The substitution of the single condenser method of operation for the partial condenser method may involve the sacrifice of the slight fractionating effect of the partial condenser, but this can be compensated for by a slight increase in the number of plates in the fractionating column or by the use of a double-effect condenser and a suitable arrangement of the dividing box.

Reduction of Hematite by Methane

While studying the reduction of iron ore by fuel gas, E. D. Eastman noted that at 700 deg. C. about one-fourth the hydrogen and CO and over half the unsaturated hydrocarbons were oxidized by reacting with iron ore, but the methane was practically untouched. C. M. Bouton, of the Bureau of Mines, verified this observation by passing a stream of mixed gas (40 per cent H_2 and 50 per cent CH_4) through a heated tube filled with fine hematite (+ 28, − 14 mesh) and analyzing the products of the reaction. If this gas take 30 seconds in passing the mass, Fe_2O_3 is reduced to Fe_3O_4 by the following reactions

$$3Fe_2O_3 + H_2 = 2Fe_3O_4 + H_2O$$
$$12Fe_2O_3 + CH_4 = 8Fe_3O_4 + 2H_2O + CO$$

the first going to completion (i.e., exhausting the gas mixture of free hydrogen) at any temperature between 600 and 900 deg. C. No CO is formed from the CO_2 or methane at these temperatures. Reduction of methane varies with the temperature, as follows:

Temperature Deg. C	Amount of CH_4 Consumed, Per Cent	K, Seconds
600	4	56,500
700	30	7,800
800	55	3,150
900	90	1,050

K is the number of seconds required for methane content of a gas to fall to one-tenth its value when the gas is agitated between walls of hematite 1 cm. apart.

In studying the reactions between gases and solids the scientists of the Bureau of Mines have erected the following hypotheses:

That the rate of reaction of each molecular species in the gas is directly proportional to the concentration of the molecular species.

That the passage of a gas through the intricate porosity of a fine ore is equivalent to passage between parallel walls of equal surface which inclose an identical volume.

That the rate of reaction of each molecular species (in terms of the percentage of the total gas) is inversely proportional to the distance between these equivalent walls.

Cascara Situation Causes Alarm

The Cascara tree, native of the Northwest, faces extinction. Unless steps are taken for its preservation and cultivation, this tree may not continue to flourish on this continent. It is cut at present as waste growth in many sections, despite the fact that its bark is of value commercially. When harvested the average tree of the Pacific coast yields 10 lb. of dry bark. Experiments conducted at the Agricultural Experiment Station on Vancouver Island indicate that the cultivation of this tree on cheap land may be fairly profitable.

Production Statistics of the Alkali Industry

The $81,884,100 Output in 1921 an 18 Per Cent Decrease From Record Total of 1919 —Soda Ash Leads

PRODUCTION statistics for one of the most formidable branches of the heavy chemical industry have just been released by the Census Bureau in the Department of Commerce. These figures show that the alkali industry of the United States had an output in 1921 aggregating in value $81,884,100, as compared with $99,689,828 in 1919, a decrease of 18 per cent.

Soda ash is the leading commodity of the group, with a production for sale of 776,520 tons, valued at $29,355,800, or 36 per cent of the group total in 1921, as compared with 1,033,480 tons, valued at $31,195,149, or 31 per cent of the total value in 1919.

Caustic soda is second, with 231,350 tons, valued at $18,434,300, or 23 per cent of the total value in 1921, and 302,121 tons, valued at $18,691,047, or 19 per cent of the total value in 1919.

TABLE I—PRODUCTION OF SODIUM COMPOUNDS IN THE UNITED STATES
(Ton, 2,000 lb.)
